AN article by Mr. Morton in a recent number of the *Journal of the American Medical Association* gives, in concluding, an excellent summary of the data which, up to the present, have been furnished by observation and experiment on the X-ray treatment of malignant growths. The net results hitherto arrived at are as follows:—(1) Relief from excruciating pain and constant suffering, often immediately; (2) reduction in the size of the new growth; (3) establishment of the process of repair; (4) removal of the odour, if present; (5) cessation of the discharge; (6) softening and disappearance of lymphatic nodes; (7) disappearance even of lymphatic enlargements not directly submitted to treatment, and often at some distance; (8) removal of the cachectic colour and appearance of the skin; (9) improvement in the general health; (10) cure, up to date, of a certain number of malignant growths.

⁂

To the subscribers to the annual volume of "St. Thomas's Hospital Reports" it is unnecessary to say anything of the wealth of information that it contains. The statistics of 5,261 cases cannot be uninteresting, particularly as they were one and all serious as shown by the death-rate, which was 10·49. An "In Memoriam" notice of the late Dr. Cory, though a little late in appearance, is very welcome and well deserved. It contains the pleasing information that Dr. Cory's widow has been granted a pension, a recognition of the heroic self-sacrifice of her husband on the altar of science. We would like to see these valuable Reports better known and more read; their analyses and summaries of cases are just such information as the physician and surgeon seek: practical and trustworthy.

⁂

Vol. X. of *The Scottish Medical and Surgical Journal* is on our table (January to June, 1902). It offers 581 pages to the curiosity of the inquiring reader, many of which contain a large proportion of interesting and valuable information. Among the articles which transgress, very instructively, the every-day boundaries of British professional routine we may mention the description of "'Latah' among South African Natives," contributed by Andrew Gilmour, M.B.; and "Extracts from the Talmud and from Celsus, illustrative of the State of Gynæcological Medical Science at the Beginning of the Christian Era," by Dr. H. M. Church. The latter forms a valuable supplement to the interesting and erudite "History of Ancient Gynæcology," produced in Australia by Dr. McKay, and recently published by Messrs. Baillière, Tindall, and Cox.

⁂

A small, but very instructive, booklet, bearing title "Les Oxydations de l'Organisme," has just been issued by Messrs. Ballière et Fils, of Paris. The authors, Drs. E. Enriquez and J. A. Licard, deal very lucidly and instructively with the recently discovered soluble ferments, which have been baptised by Duclaux with the generic appellation of *oxydases*. The field is still a vast prairie level, in which few landmarks have been firmly erected, and the overhanging firmament is not yet sufficiently luminous to enable us to focus, to our mental satisfaction, many of the local areas which the pioneers in this department have been attempting to bring under geometrical limitation and reproductive cultivation. But that there is a recuperative future before them we have little doubt; and whatever the ultimate verdict of the scientific world may prove to be, we consider that the matter and methods of their present exploration are worthy of the best attention of our professional brethren.

⁂

"Passages in the History of York Lunatic Asylum" is the title of a pamphlet comprising about eighty pages published by Mr. Charles G. Milnes-Gaskell, Chairman of the West Riding County Council. Mr. Gaskell has culled much interesting information regarding the early history of this asylum and the treatment of the insane a hundred years ago, although some may be inclined to question the justification of again bringing under public notice many degrading incidents that occurred here and elsewhere in those days. The author vindicates himself by setting forth that the influence of the early history of this hospital cannot be overrated in any account of the treatment of lunacy, and further quotes the opinion of Dr. Hack Tuke that they should be "remembered for ever as the only means of preventing their recurrence." York led the way in the beneficent reform movement, and Mr. Gaskell well deserves the gratitude of his fellow-Yorkshiremen for this interesting account of the boons won by their forefathers at the cost of much suffering and self-sacrifice.

⁂

"Protoplasm: its Origin, Varieties, and Functions," is the title of a very small volume by John W. Hayward, M.D., author of several works on medicine, sanitation, house-building and hospital construction, &c., published by Messrs. John Wright and Co., Bristol. The domain of inquiry which the writer has undertaken to elucidate in a small space is a very wide one indeed, and, as our readers—at least, those of experience—will at once surmise, the surface of the soil is but skimmed, and nowhere does the author make appreciable progress towards plucking out the heart of the mystery of organic life. Towards the end of this booklet we are informed that the grey matter of the frontal lobe of the brain is "the most highly developed protoplasm there is. It must be of an exceptionally fine quality in such brains as those of Messrs. Chamberlain and Asquith; perhaps a little less fine but more in quantity in such as those of Lord Rosebery and the late W. E. Gladstone." Dr. Hayward appears to think the *political* intellect the most "highly developed" of all. We can assure him that all members of his profession do not think so.

⁂

Books on the subject of vaccination are particularly welcome just now, and it behoves every practitioner to fortify his memory with statistics in order that he may be enabled to influence public opinion within his particular sphere in favour of more complete protection against small-pox, a disease which is always lying in wait for the unprotected or the imperfectly protected. Dr. E. J. Edwardes' "Concise History of Small-pox and Vaccination in Europe" (H. K. Lewis) supplies in a handy form the chief official statistics of Europe, and the author proceeds to urge the imperative necessity of confiding the enforcement of the Vaccination Laws to a central authority in place of the guardians, who are elected for purposes altogether foreign to the public health. The little work contains an interesting *résumé* of the history of small-pox, inoculation, and vaccination down to the Report of the Royal Commission, followed by "the great surrender." In less than 150 pages the author publishes statistically irrefragable evidence of the immense protective influence of vaccination throughout Europe. A knowledge of this important subject might well be exacted of all aspirant practitioners, but since that is not so, the omission may be remedied by voluntary effort.

Literature.

FREYER ON STRICTURE OF THE URETHRA. (*a*)

Mr. Freyer, who is so well known in this department of surgery, states that the subject contained in this volume consists of a series of lectures delivered at the Medical Graduates' College and Polyclinic. There is no class of maladies to which man is subject that causes more misery and pain than stricture of the urethra and enlarged prostate. It is therefore very convenient to take up a small and readable volume in which one can obtain at a glance a clear, concise and practical *resume* of the most recent knowledge of the subject and the methods of treatment recommended, which Mr. Freyer states he has found from personal experience to be sound and effective. Stricture of the urethra is the bane of the many in young and adult life, while enlarged prostate more or less affects every man after the age of sixty. The various points regarding stricture of the urethra together with the management of complicated cases with the various treatments recommended from time to time are clearly and concisely given.

But the last chapter on the "Total Extirpation of the Prostate in its Capsule" is the most interesting of all. On reading such a statement for the first time it is rather startling owing to our old and preconceived ideas concerning the dangers of meddling with such an organ. However, it is wonderful to observe the enormous advances that have taken place in surgical procedure in the last twenty-five years. As regards this radical operation Mr. Freyer says in his lecture, "I think I shall not be accused of exaggeration when I state that all previous so-called methods of radical cure of enlarged prostate are unsatisfactory, and that catheterism, though the least objectionable mode of treatment in the vast majority of cases, is liable sooner or later to terminate in cystitis or other dangerous complication. I submit that the results obtained in these cases of total extirpation of the enlarged prostate encourage us in the hope that we have at last arrived at a rational method of dealing with this painful and frequently fatal malady."

The reviewer of this volume was present at St. Peter's

(*a*) "Clinical Lectures on Stricture of the Urethra and Enlarged Prostate." By P. J. Freyer, M.A., M.D., Mch., Surgeon to St. Peter's Hospital, Examiner in Surgery, Durham University. Second Edition. London: Baillière, Tindall and Cox. 1902. Price 5s.

Hospital when Mr. Freyer removed the entire prostate by his method, and the simple and rapid manner by which the gland was extirpated struck him with the greatest surprise. We commend this little work to those interested as a valuable addition to the surgery of the subject.

"YEAR-BOOK OF PHARMACY. (a)

"The Year-Book of Pharmacy" for 1901 is of great interest and permanent value to members of the medical profession in that it deals very fully with the recent arsenical beer poisoning. It is unaccountable how arsenic contaminating glucose could produce toxic effects in quantities so much less than we formerly supposed possible, a toxicity greatly in excess of any of our pharmaceutical preparations of the drug. We also get an excellent summary of Ischirch's researches on resins, oleo-resins and allied substances, and of his attempt to classify resins on the rational ground of their chemical constitution. The alkaloidal assay of drugs by Gordin's method is given—a method by which a rapid and accurate determination of the basic active principles may be made.

No new remedies were introduced during the year, and of the many synthetical, so-called new, preparations introduced they were little more than proprietary mixtures introduced under catching fancy titles. If space permitted we would like to make more than passing reference to the effect of the weather on the physiology of plant life and its influence on the production of esters as shown by the effect of the unfavourable influence of the weather on the recent crop of bergamot and lemon oils, to which reference is made in the "Year-Book."

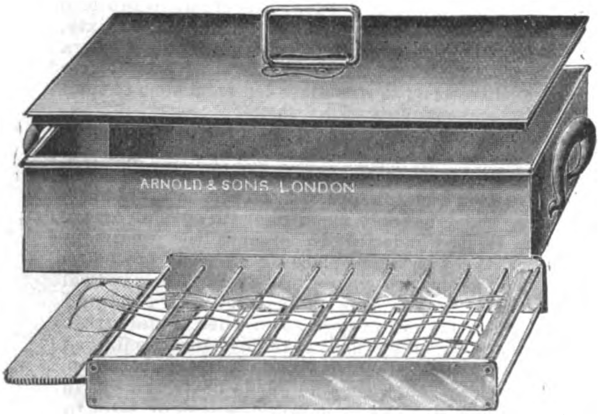
Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

A SURGICAL SILK RACK.

To the Editor of The Medical Press and Circular.

Sir,—It is strictly in accordance with the principles of aseptic surgery to boil the silk used for operations for half an hour, and to keep it boiling until the time it is inserted, and to facilitate this object, and coincidently to greatly save the time of the operator, I would ask permission to call the attention of your readers to the following device.



A rack is constructed the appearance of which is illustrated in the accompanying sketch. It consists of two parallel metal sides united by parallel steel bars at right angles to the sides. The disposition of the bars need not be described, suffice it to say that their thickness and distance apart has been the subject of experiment. At one end is stretched horizontally, between two adjacent bars, linen, or preferably Billroth's cambric, extending from one side to the other. A similar arrangement is made at the opposite end diagonally. Projecting beyond the end of the rack proper is a horizontal tray, constructed of cambric, stretched on steel wire. All the metal work is thickly nickelled, and the apparatus is not liable to rust. The device is made in two sizes. The larger size, for use in the theatre of a hospital, is 13 inches long, 7½ inches wide, and 1¼ inches high, and the tray projects 2¼ inches, making the total length 15¼ inches. The smaller size for use at single, or it may be emergency operations, is 7½ inches over all, 3 inches wide, and 1 inch high.

The use of the rack is this: The needles are threaded with the silks to be used and fixed in the rack as described later on. The rack is boiled in a steriliser for half an hour, and kept boiling until the silk is required. The lid of the steriliser is removed, and the surgeon selects with forceps whatever needle and silk he requires. By pulling the needle from the tray and gently dragging on the silk the needleful is extracted with certainty, and removed for use without causing any tangling of the other contents of the rack. The larger rack when fully loaded will hold sufficient silk for half a dozen major operations. The smaller will comfortably hold sufficient for one or two. The racks should be boiled up again between the operations.

The loading of the rack is accomplished in the following manner:—The needles are threaded and the ends of the silk adjusted to approximate equality, the rack is turned on its side and a needle passed through the stretched cambric, and then over and under alternate bars in the same row until the tray is reached. Into this the point of the needle is stuck, the silk pulled moderately tight, and the loose ends cut off to within one inch of the stretched cambric. Both ends of the silk are fixed by this proceeding. One should start at one side of the rack with thick silk and large needles and proceed towards the other side with ever decreasing thicknesses of silk. Each needleful should not only be threaded over and under alternate bars, but should also alternate with the threads on each side of it, just as the woof crosses the warp in weaving.

In the smaller rack the starting-point is at the same end as the tray, and on the lower set of bars. In the larger form if the length of the doubled thread is desired greater than the length of the rack, the starting point is on the lower set of bars and a transition is made to the upper set after a suitable number of bars has been passed. The rack may be loaded with any length of silk up to eight times the length of the rack with the certain knowledge that the silk may be readily extracted when required.

If unthreaded "*ligatures*" are required, they are loaded in a similar manner except that they are single, and that after having been put in place the needle is removed. Great lengths of silk may also be sterilised by merely winding the silk round and round the four corner bars, which are placed on a different level from the others for this purpose.

If the loading is done in a systematic manner it only takes three-quarters of an hour to completely fill the large rack with silk. The most convenient sizes for an average afternoon's operations are:—

No. 3 silk ... 12 straight and 6 fully curved needles
No. 1 „ ... 3 „ „ 3 „ „ „
No. 00 „ ... 9 small „ 9 „ „ „

The advantages claimed for the apparatus are these: First, the silk is, often unlike the deeper layers of silk on a boiled reel, sterile at the time it is used. Second, any kind of silk on any kind of needle may be selected and obtained by the operator with great speed, often with the saving of valuable time. Third, the silks do not get entangled; indeed, the ease with which they may be extracted is quite remarkable.

The above pieces of apparatus may be used in any steriliser large enough for the purpose. It is, however, much more convenient to have one to fit the apparatus. The one supplied has a simple device which, while it allows the easy lifting out of the rack yet prevents its displacement when in use. The steriliser is also of such a size as to leave a space two inches wide for the coincident boiling of drainage tubes. Such a steriliser is kept boiling in the annexe to the theatre, and when required is brought in and used. It should not be laid directly on a towel-covered glass table, for the glass is liable to crack, but on a wooden or asbestos pad placed to receive it. The above apparatus is made in a most excellent manner by Messrs. Arnold, of West Smithfield, from an experimental model of my own construction.

(a) "Year-Book of Pharmacy:" comprising Abstracts of Papers relating to Pharmacy, Materia Medica, and Chemistry, contributed to British and Foreign journals, from July 1, 1900, to June 30, 1901. London: J. and A. Churchill. 1901.

WHOOPING-COUGH IN PUBLIC CONVEYANCES.

To the Editor of The Medical Press and Circular.

Sir,—Travelling as I do a good deal in omnibuses and tramcars, I have been struck by the recklessness with which children suffering from whooping-cough are allowed to avail themselves of this mode of conveyance, with utter disregard, possibly in utter ignorance, of the extreme infectiousness of this troublesome and, in the aggregate, fatal malady. Whooping-cough not being scheduled as a notifiable infectious disease, no restrictions are apparently enforced in respect to the liberty to circulate of persons suffering therefrom, a lapsus in our sanitary administration which calls for immediate attention.

I hardly know to whom to address this suggestion, and I therefore avail myself of your columns in the hope that it may attract the attention of those with whom it rests to deal with the matter.

I am, Sir, yours truly,
Practitioner.

Medical News.

Small-pox in London.

The number of patients suffering from small-pox actually under treatment in the hospitals of the Metropolitan Board has now fallen to ninety, only twenty-five fresh cases having been admitted during the fortnight ending Saturday last. The report of the Committee on the communication from the Local Government Board, enclosing for the managers' observations, prints of a draft order prescribing fresh regulations with regard to the use of the small-pox hospitals for purposes of medical instruction, states that, after carefully considering the terms of this draft order, they had made application to the Board to issue the order subject to provision being made therein empowering the managers to determine from time to time the fees to be paid to the medical superintendent who might act as clinical instructor. Under Clause (3) of the draft order, the managers might make regulations in regard to the mode of conveyance to and from the small-pox hospitals and disinfection and discipline of students, provided that no such regulations should come into force until they were confirmed by the Board, and the committee had accordingly asked the Board to sanction the draft rules and regulations on this subject which were adopted by the managers on February 8th, 1902. It was reported that the admission of small-pox patients to the hospital ship had been suspended as from July 19th last.

A Munificent Donation.

It is announced that the Committee of King Edward's Hospital Fund for London has just received a magnificent endowment due to the generosity of Lord Mount-Stephen and Lord Strathcona, a gift estimated to produce £16,000 per annum at present, with a prospect of more in the future. An annual subscription of £500 by Sir Savile Crossley, M.P., is also promised.

Deaths under Chloroform.

An inquest was held on the 1st inst. at St. Pancras on the body of a man, æt. 40, who had succumbed at the workhouse to the effects of an anæsthetic administered for the purpose of an operation. A verdict of death from misadventure was returned. A death from the same cause is reported from Croydon, the victim being a man about to undergo a dental operation. It is unfortunate that in the reports of these inquests no information is usually forthcoming on the points which would assist us in elucidating the cause of the catastrophe, a catastrophe which, in a certain, but unascertainable, proportion of the cases, might doubtless be averted by more scientific methods of chloroform administration.

No Poison Label.

An inquest was held at Battersea a few days since on the body of a young married woman, who had succumbed to the effects of an overdose of morphine, taken under somewhat peculiar circumstances. It seems that her mother, who was suffering from cancer, was in the habit of taking large doses of morphine supplied by a local practitioner who had also supplied some medicine for the younger woman. The two bottles being very similar, the daughter took a dose from the wrong bottle, each dose of which contained two grains of the alkaloid. The sad occurrence suggests the propriety of affixing a caution label to medicines containing doses of a drug which would be lethal to others than the person for whom it is intended.

Cholera in Egypt.

The epidemic of cholera in Egypt is still in the period of extension, and during the four days ending Saturday last there were close upon 5,000 fresh cases, three-quarters of which proved fatal. Down to Wednesday of last week there had been 14,500 cases, with only 1,183 recoveries. It is anticipated that for some days to come we may anticipate some 1,500 fresh cases daily, and it will not be until towards the end of October that any notable decrease can be looked for. In Cairo itself there are marked indications of improvement, and this remark applies to most of the large towns.

Sudden Death of a Medical Practitioner.

Mr. Frederick Pratt, M.R.C.S.E., of Appledore, died suddenly while in attendance on a parturient woman, on the 3rd inst., the cause of death being heart disease.

A Public Vaccinator Asked to Resign.

Dr. Nix, Public Vaccinator to the Bury St. Edmunds Board of Guardians, originally sent in a bill for vaccinations amounting to upwards of £390, which was subsequently reduced by him to the comparatively modest figure of £50. At a recent meeting of the board surprise was expressed that he had not apologised for his mistake, and it was decided to request him to send in his resignation.

Dublin Death-rate.

The deaths registered in the Dublin registration area during the week ending Saturday, August 30th, 1902, represent an annual rate of mortality of 21·5 in every 1,000 of the population. Diseases of the nervous system caused 14 deaths; of the circulatory system, 18 deaths; and of the respiratory system, 16 deaths. Fifty-three infants died during the week, of whom 23 were under twelve months old. Within the city proper the death-rates in the following districts of Clarence Street North, Blackhall Place, and Castle Street were 29·9 per 1,000, 26·3 per 1,000, and 30·5 per 1,000 respectively.

Municipal Trading.

The Battersea Borough Council has for the last three months undertaken the task of supplying sterilised milk for the use of infants, and the innovation, we are assured, has met with a greater measure of success than was anticipated. Three different strengths of milk are prepared; one for children under three months, one for those under six months, and the third is intended for children up to a year. The milk when first received is filtered and diluted with the necessary amount of water. Cream and lactose are added to bring the milk up to the standard of human milk. It is then poured into stoppered bottles, which are placed, 500 at a time in the sterilising chamber. By means of steam jets the temperature is raised to about boiling point, at which it remains for a quarter of an hour. All germs are thus killed. The charge made for milk is 3d. per day, or 1s. 6d. per week for the full quantity required.

Medical Inebriety.

A Mr. Allan Wilson, described as a medical man, was fined for being drunk and disorderly at Horncastle, Lincolnshire, last week.

Notices to Correspondents, Short Letters, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REMEMBER!

A correspondent suggests the following points in respect of pericarditis:—

Pericarditis.

Remember that the pericardium is a visceral joint.

Any cause which may give rise to inflammation of a joint may give rise to pericarditis.

Remember that pericarditis may usher in an attack of rheumatic fever.

Remember that pericarditis may be latent as in some renal cases, in which it may occur as a complication.

Remember in tuberculous pericarditis that if the left side of the chest be fixed by strapping, pain and dyspnœa will be relieved.

Avoid blisters in cases of pericarditis of renal origin, and remember that opium is badly borne by patients whose kidneys are incompetent. If effusion be present remember that the fluid may be (1) serum, (2) blood, or (3) pus. Therefore use an exploring needle of sufficiently wide calibre. A hypodermic needle is in many cases useless.

If the effusion be small, explore in the fifth intercostal space 1½ ins. from the left sternal border, thus avoiding the left internal mammary artery which runs down 1 in. from that border.

If the effusion be extensive explore in the left xiphi-costal angle in the direction directly upwards. Remember that every young anæmic girl complaining of dyspnœa and left infra-mammary pain is not simply a case of anæmia and hysteria, but may be suffering from pericarditis. Therefore in every case carefully examine the patient's chest.

In fifty cases a hæmic bruit only may be present, but in the fifty first early signs of pericarditis may be discovered.

Nemo.—There is really no occasion to invent a "tasteless" castor oil—the pure oil is normally tasteless, and it is the odour to which patients object. If the nose be firmly held during ingestion, and the mouth thoroughly cleansed before permitting the entrance of oil no inconvenience will be experienced.

THE CONSUMPTION OF TEA.

In 1882 the quantity of tea imported into France amounted to 475 tons. In 1895 it was 728 tons, and in 1901 861 tons. For the last four years the consumption of tea has remained stationary. As matters stand this consumption works out at only three-quarters of an ounce per head of the population as against 6 lb. per head in Russia, and 5 lb. per head in England. In the United States the quantity per head is estimated at about 1 lb., but tea seems to be giving place to coffee. In other countries, Switzerland stands at 1½ lb. per head, Germany at ¾ lb., Belgium about 2¼ ozs., Spain 1½ oz., and in Italy only ½ oz. per head.

D. I. (London).—We are ignorant of the nature of the proprietary medicine to which you refer, and cannot therefore offer any opinion as to its innocuousness. The practice of taking self-prescribed nostrums is one fraught with manifest dangers. Intellectual fatigue is not to be fought by drugs. It would be far better to seek skilled advice as to the cause of the debility and the means of preventing it.

GARNAULT *VERSUS* KOCH.

The *N. Y. Medical Record*, commenting upon the acrimonious remarks made by Koch on Garnault and *vice versa*, recalls that Koch accused Garnault of "playing to the gallery" by experiments which were neither scientific nor even serious. Garnault, much piqued, replied by calling Koch a "poseur" and a plagiarist. Our contemporary concludes that both parties are right in this wordy war—in their characterisations of each other.

Mr. A. R. Simson.—Your letter is much too long for our columns, moreover the subject has been already adequately dealt with.

DEPRAVITY IN WORDS.

If the Americans like to add new and outlandish words to their private language, that is exclusively their affair. But it is not altogether pleasant to find some of these words creeping into English newspapers. Latterly that most atrocious word, "electrocute," has made its appearance in more than one London newspaper. It was evidently invented by a man who fancied that "cute" meant "kill." Hence, if a man was killed by electricity he was said to be "electrocuted." There is no limit to the extent to which this system of inventing new words might be carried, says W. L. Alden in *Gossip*. If a man is drowned he may be said to be "watercuted." Similarly he may be "knifecuted," or "poisoncuted"; or "firecuted" if he is burned to death, or "traincuted" if he is killed on the railway, or "talkcuted" if he is a member of the House. Of all the words which have been recently thrust into the last edition of the biggest dictionary in the world, "electrocuted" is the most utterly depraved and infamous.

Appointments.

Bernstein, Julius M., L.R.C.P., M.R.C.S.Eng., House Physician at the Manchester Royal Infirmary.

Bowdler, A. Penrhyn, M.A., M.B., B.C.Camb., L.R.C.P., M.R.C.S., House Physician to the Victoria Hospital for Children, Chelsea.

Crow, John, M.B., Ch.B.Glasg., Certifying Surgeon under the Factory Act for the Large District of Ayrshire.

D'Ewart, John. M.R.C.S., L.R.C.P., House Physician at the Manchester Royal Infirmary.

Ellerton, H. Byam. M.R.C.S.Eng., L.R.C.P.Lond., Senior Assistant Medical Officer to the Metropolitan Asylum for Imbeciles, Leavesden, Herts.

Merrick, Ferdinand R. H., M.D.Dubl., Medical Officer of Health of the Rural District of Basingstoke.

Moore, W. B. A., L.R.C.S., L.R.C.P.Irel., Resident Medical Officer Mercer's Hospital, Dublin.

Tylecote, J. H. L., M.B., Ch.B.Vict., Chief Medical Officer of the Gold Coast Government Railway.

Valentine, W. R., M.D., B.Ch.Dubl., Honorary Surgeon to the Bideford and District Dispensary and Infirmary.

Walker, T., M.R.C.S., L.R.C.P., House Surgeon at the Manchester Royal Infirmary.

Wilkins, Arthur G., M.B., Ch.B., Resident Medical Officer to St. Mary's Hospital for Women and Children, Manchester.

Vacancies.

Clifden Union.—Midwife. Salary £25 per annum. Immediate applications to F. King, Clerk of Union. (See advt.)

County Borough of Northampton.—Medical Officer of Health. Salary £500 per annum. Applications to Herbert Hankinson, Town Clerk, Guildhall, Northampton.

County Mayo Infirmary.—House Surgeon and Compounder. Salary £109 per annum, with apartments, &c. Applications to Dr. O'Malley Knott, Mayo Infirmary, Castlebar. (See advt.)

Denbighshire Infirmary, Denbigh.—House Surgeon. Salary £100, with board, residence, and washing. Applications to W. Vaughan Jones, Secretary.

East Sussex New Lunatic Asylum.—Medical Superintendent. Salary £900 a year, with unfurnished house, electric light, coals, vegetables, milk, and washing. Applications to Reginald Blaker, Clerk of the Visiting Committee, 211, High Street, Lewes.

Glenties Union.—Medical Officer. Salary £100 per annum Applications to Michael M'Nelis, Clerk of Union. (See advt.)

Liverpool Dispensaries.—Assistant Surgeon. Salary £100 per annum, with board and apartments. Applications to Sam. B. Leicester, Secretary, 56, Vauxhall Road, Liverpool.

Liverpool Infectious Diseases Hospitals.—Assistant Resident Medical Officer. Salary £120 per annum, together with board, washing, and lodging at the Hospital. Applications to the Chairman of the Port Sanitary and Hospitals Committee, under cover to the Town Clerk, Municipal Offices, Liverpool.

Morpeth Dispensary.—House Surgeon. Salary £120 per annum, with furnished rooms and attendance. Applications to Honorary Secretary.

North-Eastern Hospital for Children, London.—Resident Medical Officer. Salary £120 per annum, with board, residence, and washing allowance. Applications to T. Glenton-Kerr, Secretary, 27, Clement's Lane, London, E.C.

Pharmaceutical School of Botany and Materia Medica, Ireland.—Professor of Materia Medica. Applications to Arthur T. Ferrall, Registrar. (See advt.)

Roxburgh District Asylum, Melrose, N.B.—Assistant Medical Officer. Salary £120 per annum, with board, rooms, and washing. Applications to the Medical Superintendent.

Southwark Union, London.—Second Assistant Medical Officer at their Infirmary, East Dulwich Grove, S.E. Salary £100 per annum, with board, lodging, and washing. Applications to Howard C. Jones, Clerk, Union Offices, John Street West, Blackfriars, S.E.

Births.

Arkwright.—On Sept. 5th, at Halesowen, the wife of Joseph A. Arkwright, M.D., of a daughter.

Berry.—On Sept. 3rd, at Richmond House, South Lowestoft, the wife of Walter Berry, M.D., of a daughter.

Bulleid.—On Aug. 30th, at Midsomer-Norton, the wife of Arthur Bulleid, L.R.C.P., L.R.C.S.Ed., of a daughter.

M'Clintock.—On Sept. 1st, at Rowley, Church Stretton, the wife of John M'Clintock, L.R.C.S.Ed., of a daughter (prematurely).

Marriage.

Fox—Lewis.—On Sept 3rd, at All Souls' Church, Langham Place, London, W., Campbell Tilbury Fox, F.R.C.S.Eng., L.R.C.P. Lond., of Ashford, Kent, son of the late Tilbury Fox, M.D., F.R.C.P., to Hilda Lewis, daughter of A. Lewis Esq., of Seaham Harbour, Co. Durham.

Holzberg—Korthals.—On Sept. 8th, at St. George's Church, Hanover Square, London, Albert Holzberg, E.A., Ph.D. Principal of Heidelberg College, Heidelberg, to Henriette Gertrude, only daughter of W. C. Korthals, formerly Dutch Consul, Japan.

Horder—Doggett.—On Sept. 3rd, at the Parish Church, Newnham, Herts, Thomas Jeeves Horder, M.D.Lond., M.R.C.P., 141, Harley Street, London, W., youngest son of the late Albert Horder, Wincombe, Swindon, to Geraldine Rose, only daughter of Arthur Doggett, Esq., of Newnham Manor, Baldock, Herts.

McGinn—Murphy.—On Sept. 6th, at St. Peter's Church, Cardiff, John McGinn, L.R.C.S.I., of Newport, Mon., to Florence Louise, younger daughter of Arthur J. Murphy, of Llantarnam.

Deaths.

Ashley.—On Sept. 3rd, at 3, Sion Hill, Clifton, Bristol, Ambrose Humphreys Ashley, M.R.C.S., &c., late H.E.I.C.S., aged 87 years.

Aveling.—On Sept. 5th, at Mullion, Cornwall, whilst bathing, Charles Taylor Aveling, M.S., M.D.Lond., F.R.C.S., late of Stamford Hill, aged 58 years.

Grant.—On Sept. 2nd, at Ninnage Lodge, Westbury-on-Severn, Henry Sanders Grant, M.R.C.S., aged 76.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

VOL. CXXV. WEDNESDAY, SEPTEMBER 17, 1902. No. 12.

EDUCATIONAL NUMBER, 1902—1903.

INTRODUCTORY REMARKS.

THE conditions of medical education have undergone considerable modification during the past quarter of a century, but the First of October remains a red-letter day in the medical student's career. Not of course that this date marks the epoch of the momentous decision in virtue whereof the young man, not long since liberated from the strict discipline of school life, enters his name at a recognised school of medicine. It remains for the most part the day of the *entrée en scène*, the day when, for the first time, he enters into possession of his status as a medical student; when, for the first time, he is brought face to face with the surgical and medical authorities who, for a brief span of years, will constitute his intellectual horizon. By way of preparing him for his new life it is the custom — a custom gradually falling into disuse — to treat him, collectively, to an address of welcome. In this address it is traditional to sketch the main features of the career upon which the student has now solemnly entered, coloured according to the mental temperament of the lecturer, sometimes in rosy hues, sometimes with a liberal allowance of darker shades. The truth, of course, lies between the extremes. We may premise, by way of an introductory aphorism, that "Medicine is a wholly admirable profession, but for the most part it is a poor business"; in other words, while it secures to its followers a certain social position (which, however, is determined far more by personal than by professional status) it must not be expected to provide them with "wealth beyond the dreams of avarice," or even that which an equal amount of brains and energy might, with good luck, secure in the commercial walks of life. Virtue, we are assured, is its own reward, and so is very largely the practice of medicine. It is distinctly a sympathetic calling, one which brings us into contact with poor suffering humanity under circumstances which divest human intercourse of much of its acrimony and bitterness, circumstances in which it is at once a privilege and a pleasure to minister to the requirements of those who look to us for assistance.

A lawyer is of service at most in his own country, his ministrations are limited to the territory within the jurisdiction of the courts to which he owes allegiance. The medical man, on the other hand, is cosmopolitan, his nationality, his language, his creed, are lost sight of provided only that in case of need he can render the precious services which are his prerogative irrespective of environment. *Acta non verba* is his maxim, and the object and aim of medical education is to place it within his power to put that maxim in practice in assuaging suffering and prolonging life.

There are no Lord Chancellorships in medicine, and politics, which, in the legal world, are often the stepping stone to promotion, are injurious to the practice of medicine and inimical to the pursuit of studies which tend to extend the horizon of medical science.

Medicine, then, is a career only to be entered upon by those who are willing to live a life of sacrifice and abnegation in exchange for a modest but assured livelihood. The labourer is worthy of his hire, but he must not expect more. The medical practitioner must not expect great social success, honours, and sittings in the seats of the mighty. It is quite open to question whether such things are intrinsically worth striving after, whether in fact they are legitimate aims in life. Such honours, when they come, are of value, less in that they honour the individual than because they testify to public appreciation of the profession. If they are not more frequently the lot of the practitioner of medicine it is doubtless because the practice of medicine is not a calling in which the merits of its adepts are proclaimed from the housetops, the newspapers do not chronicle its heroism, and it occupies a subsidiary place on the world's stage; moreover, even the leaders of the profession are rarely rich enough to support the burden of embarrassing dignities or hereditary honours.

THE MEANS AND THE END.

Much might be written in regard to the choice of a school, large or small, metropolitan or provincial, but the choice is almost invariably made on other than purely reasonable grounds. Often it is decided by parental example, sometimes having regard to the question of comparative fees, and at others it is decided by fortuitous circumstances. The self-controlled, strong man, especially if he has already had the advantage of a period of university training, will find most scope in the large schools, where competition is fiercest but where the prizes are more important. The younger student, as yet hardly fit to be entrusted with his own destiny, will be better looked after in one of the smaller schools where the staff take a keener personal interest in their pupils. But ere now the die is cast, and it only remains for the student to survey the *champ de manœuvres* and do his best.

Of greater immediate importance is the choice of qualifications, for this is a point which has to be decided at the very onset of the student career. Not so many years ago the membership of the College of Surgeons with, perhaps, the licence of the Apothecaries' Society, was held to be amply sufficient for general practice. Nowadays, however, even with the licence of the College of Physicians thrown in, mere diplomas are looked at askance by all save the unambitious. Not that the diploma of the Conjoint Boards indicates other than a high standard of professional attainments; indeed, as a matter of fact, the examinations are as severe, and their diplomas as difficult to obtain, as those of most universities. The northern universities, however, have flooded the country with graduates who, on the strength of the M.D., are credited by the public with superior professional attainments, in such wise that the college diplomate who is not technically entitled to assume the title of "Dr." finds himself in an invidious position in practice, hence the very general desire to obviate any drawback of this kind. The difficulty has been surmounted in the provinces to a great extent, thanks to the multiplication of universities, but in London matters are still in a stage of transition. Under existing circumstances the student at a London school will be well advised to enter for the London University course, although there is every prospect that before those now commencing their studies have completed the curriculum the colleges will have become affiliated to the university.

The Course of Study.

Owing to the numerous additions which have been made to the curriculum and to the steady rise in the standard of knowledge required of students all round, the extended period of five years will be found none too much for the work to be done within that time. The student therefore will find it necessary to start methodical work at once. He begins with anatomy, physiology, and materia medica, the threefold basis of practical medicine, assuming that he has availed himself of the facilities afforded him to get through his preliminary scientific work before entering a medical school. He should especially bear in mind that medicine is a practical science, and that the value of his knowledge will be in proportion to its practical bearings. The importance of actual dissection cannot be over-estimated, for no amount of mere book work can confer on him that familiarity with the anatomical structure o the human body which is indispensable to useful work later on. The study of practical anatomy is a valuable mental training, to say nothing of the manual dexterity which is acquired by careful dissection. Hardly less important is it to acquire an individual knowledge of the physical characteristics of drugs and their properties. The great majority of students will, later on, have to dispense their own medicines, and to do this with safety to the patient and credit to themselves necessitates a certain familiarity with the substances employed. The student should bear this fact in mind, especially as the licensing bodies of late display a tendency to treat this department of study with less respect than it merits.

The Clinical Work.

It is in the wards and in the out-patient department after all that the student acquires most of his information concerning the course and treatment of disease. There he watches the daily progress of morbid processes, and learns the means employed to afford relief or to bring about recovery. It will be his privilege to unravel the tangled threads of each patient's life history, and by the careful collection and careful examination of data to arrive at a reasoned conclusion known as the diagnosis. In this way he will gradually learn to recognise the main principles which underlie the practice of medicine. Each patient who comes under his observation will, if properly studied, yield his quota of practical knowledge, and the value of the opportunity depends upon the ability and willingness of the student to avail himself thereof. The object and aim of clinical training is to cultivate the student's powers of direct observation and to train him to make correct deductions, and the habit of careful observation is one which should become second nature. The instruction received in the wards is incomplete unless supplemented by the lessons to be learned in the post-mortem room. The post-mortem examination is the touchstone of diagnosis and, in some cases, the opprobrium of treatment. There the student can follow the morbid process to its logical conclusion. The post-mortem room is the natural complement of the ward, and it is often only in this room that the clinical problem is unravelled and the student enabled to observe the organic lesions which determined the symptoms he has been studying. Incidentally the student should learn as much as he can of the method of carrying out these examinations, for it falls to the lot of most practitioners to have to make such examinations, and errors of observation or appreciation may be fraught with the gravest consequences to possibly innocent persons.

The Higher Qualifications.

There remains the question of the higher qualifications, *e.g.*, the Fellowships of the Royal Colleges, which are indispensable to those who contemplate a hospital career either as physician or surgeon. The Fellowship of the Royal College of Physicians is not obtained by examination but by selection from among the members. Candidates for the membership are required to pass a searching examination and to satisfy certain other requirements before they can be admitted thereto, and subsequent elevation to the Fellowship is largely a matter of personal influence, though merit *per se* is not a bar to selection. The Fellowship of the Royal College of Surgeons, on the other hand, is a purely professional distinction, and is open to anyone who can pass the examinations. It is advisable to pass the first examination for the Fellowship as soon as possible after passing the first membership in order not to have to go over the ground afresh later on.

Choice of a Career.

For five long years at a minimum the student's ambitions do not soar beyond the boards of examiners. To obtain the right to practise is, for the time being, the object of his existence. When he has entered the portals of the profession he is confronted with the troublesome question of deciding in what particular direction he shall direct his energies. Many neo-practitioners, not unwisely, spend a year or two in resident appointments at their own hospitals or at some provincial hospital, infirmary, &c. Others acquire a knowledge of the practice, as distinguished from the theory, of medicine by serving as assistant or locum tenens. Others, again, either join their parents in practice or purchase partnerships. Then, too, there are the Services—Indian, Army, Navy and Colonial—to choose from. The Poor Law Infirmaries provide each year a certain number of appointments, and these are the first rungs of the ladder which leads to the superintendency of these institutions. These posts are fairly remunerated, and afford reasonable security of tenure, but they entail much hard work, together with heavy responsibilities.

Public Health Service.

Every student who can afford the time is strongly advised to qualify in State Medicine, since this diploma renders its holder eligible for appointment as medical officer of health, and moreover the knowledge thus gained is invaluable in every department of practice. A diploma in State Medicine entails a special course of preparation and training subsequent to qualification, the conditions of which will be found under the appropriate heading. Although the tenure of office is not as yet on a satisfactory basis, there are many valuable appointments of the kind which afford magnificent scope for intelligent activity.

Post-Graduate Instruction.

Medicine, with its continually widening scope and added requirements, has become a field of vastly greater extent than was the case a few decades ago, and when he enters upon his professional work the conscientious practitioner is apt to experience a painful sense of his shortcomings in very many branches of medical practice. The knowledge which has been rendered available of recent years has obviously placed a peculiar responsibility upon the physician fresh from his studies. The desire so generally felt by men in practice to extend and complete their knowledge of special subjects has led to the organisation of post-graduate institutions on a large scale, of which advantage is freely taken by those who are fortunate enough to reside within accessible distance thereof. We would strongly urge senior students and young practitioners to avail themselves of every opportunity to acquire a working knowledge of the various special branches—eye, ear, throat, gynæcology, &c. This leads us to the question of

Specialism in Medicine.

Hitherto the student has been taught that "the greatest mistake of all is to start in a specialty without being thoroughly grounded in general practice." Admitting that it behoves everyone, no matter what particular department of practice he may decide to adopt, to have acquired a thorough grounding in the general principles of medicine, it is impracticable for him to devote much time to general *practice*. On the contrary, there is much to be said in favour of the view that it is best for the young practitioner to make his choice at the earliest possible moment of the line of work which he designs to follow. Vacillation at this early stage of his career does not tend to beget confidence among his elder colleagues, and certainly does not improve his chances of making a reputation as a specialist. As soon as he has qualified, therefore, or as soon after as may be, the intending specialist should endeavour to obtain a junior post in one or other of the special hospitals, where he can gradually work his way up.

Medical Practice in Foreign Countries.

Practitioners qualified in Great Britain who desire to practise their profession abroad are still confronted with many difficulties. True, a step in the direction of reciprocity has been taken in the case of Italy, but elsewhere in Europe considerable difficulty will be experienced in obtaining permission to practise; indeed, with the one exception of Italy, it is usually necessary to go through the whole curriculum and pass the totality of the examinations. These special requirements will be found elsewhere.

LONDON SCHOOLS.

The Schools of Medicine in the Metropolis are the following, the scholarships, prizes, students' appointments, fees, &c., being set forth in connection with each place named. The names of the hospital staff, lectures, residential terms, and detailed information will be found, as a rule, in our advertisement columns.

St. Bartholomew's Hospital.—This hospital has 750 beds, and for many years past the school attached has had a larger number of entries than any other medical school in London. Collegiate residence is here permissible, subject to the ordinary rules. The recreation ground for the use of students is at Winchmore Hill.

Appointments.—Ten house physicians and ten house surgeons are appointed annually. During the first six months of office they act as "junior" house physicians and house surgeons, and receive a salary of £25 a year. During their second six months they become "senior" house physicians and house surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant and an ophthalmic house surgeon are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two assistant anæsthetists are appointed annually, and receive salaries of £120 and £100 a year respectively. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. Two assistant electricians are appointed every six months, and in-patient dressers, in-patient clinical clerks, clerks and dressers to the assistant physicians, and to the physicians and surgeons in charge of special departments are appointed every three months without fee.

Scholarships, &c.—There are four open scholarships in science, £75, £75, £150, £50, tenable for one year, and a Jeaffreson exhibition, value £20: at the end of first year four junior scholarships of £30, £20, £25, £15, respectively; Treasurers' prize for practical anatomy: Foster prize in practical anatomy; senior scholarships, value £50, for anatomy, physiology, and chemistry; Wix prize, Hichens prize, Lawrence scholarship and gold medal, value 40 guineas, for medicine, surgery, and midwifery; two Brackenbury scholarships, of £39, in medicine and surgery: Bentley prize, for reports of surgical cases; the Kirkes gold medal for clinical medicine, with scholarship of £30 Shuter scholarship of £50; Skynner prize of £15: Sir G. Burrows' prize of £10 and Matthews Duncan medal and prize, value about £20; the Treasurer's Research Studentship, of the value of £100, is given annually, the elected student being required to engage in original research in pathology.

Fees.—Fees for perpetual attendance on lectures and hospital practice, 160 guineas, payable in the following instalments:—First year, 40 guineas; second year, 40 guineas; third year, 40 guineas; fourth year, 40 guineas; or a single payment of 150 guineas. Fee for general subjects for students of general surgery: First winter, 31½ guineas; first summer, 31½ guineas; or a single payment of 63 guineas. Fee to University students, 80 guineas; fee for laboratory instruction for D.P.H., 15 guineas; composition fee to University of London students for one year's instruction for the Preliminary Scientific Examination, 20 guineas. Composition fee to University of London students who have passed the preliminary scientific examination, 150 guineas.

The Warden, Dr. James Calvert, will furnish further details on application.

Charing Cross Hospital.—The school attached to this hospital is situated in central London, and contains new physiological, pathological, and bacteriological laboratories, materia medica museum, an anatomical theatre, enlarged dissecting-room, and chemical theatre. The hospital and convalescent home contain 260 beds available for clinical study.

Clinical instruction is given in medicine, surgery, and obstetrics, and in the special department, diseases of the skin, diseases of children, mental disorders, the throat, the eye, nose and ear, and in the orthopædic, Röntgen, and electrical departments.

Scholarships, Medals, &c.—Five entrance scholarships, the Livingstone scholarship, 60 guineas, and 55 guineas; Huxley scholarship, 40 guineas and 30 guineas. Three (100 guineas, 60 guineas, and 40 guineas) are open to all general students, one (55 guineas) is reserved for the sons of medical men, and one (30 guineas) is open to dental students only. All are awarded annually. Two Universities scholarships, value 72 guineas each, are open to students from the University of Oxford who have passed the 1st M.B., to students of the University of Cambridge who have passed the 2nd M.B., and to students of the University of London who have passed the intermediate examination in medicine. Candidates must give notice to the librarian of their intention to compete on or before September 21st, 1902. The Golding Prize of £10 is open to students at the end of their first winter session. The Huxley Medal, with prize of £10, is open to students at the end of their second winter session. The Pereira Prize of £5 is open to all general students. The Llewellyn Prize of £25 is awarded annually at the end of the curriculum. The Governors' Clinical Gold Medal is also open to students at the end of their curriculum, and a silver medal or its equivalent in books is awarded to the most distinguished student in each class.

Appointments.—The curator and pathologist is appointed annually, and receives £100 a year; medical and surgical registrars to the hospital receive £40 a year each, with luncheon in the hospital; obstetric registrar, six house physicians, six house surgeons, and two resident obstetrical officers are appointed each year; clinical clerks, dressers, and surgical ward clerks are appointed in all the general and special departments of the hospital.

Fees.—For the curriculum of study required by the various examining bodies and hospital practice, 110 guineas in one sum, or 121 guineas in five instalments.

The composition fee for sons of registered medical practitioners is 110 guineas, and the fee by instalments, 121 guineas. For dental students, 54 guineas in one sum, or 60 guineas payable in two instalments.

St. George's Hospital.—This hospital is situated in a favoured position in the West End, facing Hyde Park. It contains 350 beds, and special wards for ophthalmic cases and diseases of women.

Appointments.—Four house physicians and four house surgeons, entitled to reside and board in the hospital free of expense; two assistant house physicians, two assistant house surgeons, four assistants in the special departments. Candidates for the above offices are selected quarterly by competition from among the perpetual pupils, and hold all the offices in succession during a period of two years, sixteen pupils being in office at any one time. Obstetric assistant with a yearly salary at the rate of £100 and board and residence in the hospital; pathological curator with a salary of £100; assistant curator with a salary of £50; two medical registrars, with salaries of £50 and £30 per annum; a surgical registrar with a salary of £50 per annum; an administrator of anæsthetics with a salary of £50 and two with salaries of £30 per annum; a surgery officer with a salary of £100 a year; two or more demonstrators of anatomy with a salary of £50 each; and assistant demonstrators. All offices are open to candidates without additional fee.

Exhibitions, &c.—The Brown exhibitions, one of £100 per annum, tenable for two years, and open to perpetual pupils possessing a registrable diploma; and one of £40 per annum, tenable for three years and open to students of two years' standing or upwards, who at the time of competition have not been qualified to practice medicine and surgery for more than three years. The Brackenbury prizes of the value of £40 each, one each in medicine and surgery. The Webb prize in bacteriology, value £30. The Clarke good conduct and clinical work prize in surgery, the Thompson medal, the Brodie clinical prize in surgery, the Johnson prize in anatomy, the Pollock clinical prize in physiology, the Treasurer's prize for clinical reports, and four general proficiency prizes of ten guineas each.

Scholarships.—One in Arts of £150 for sons of medical men who have entered the school during the current year. One in Arts, of £50, open to students under twenty years of age. Examination, September 24th. Two of £85 in anatomy and physiology, open to students who have signed up for or passed the first M.B. Oxford or second M.B. Cambridge. One of similar value for students of Provincial University colleges of similar standing Examination, September 24th.

Fees.—Composition fee for perpetual pupils, £150, or £160, in the following instalments: First year £50, second year £50, third year £40, fourth year £20. The fee for general subjects in dental surgery is £55, payable in two instalments: first year £30, second year £25. Only perpetual pupils can hold house office or compete for the Brown exhibitions.

Guy's Hospital.—This hospital is situated on the Surrey side of London Bridge, and contains 650 beds with special wards for ophthalmic and obstetric cases. A special ward has now been set apart for diseases of women, eight beds being appropriated for difficult cases of labour. An obstetric registrar and tutor and an ophthalmic registrar and tutor have been appointed to augment the teaching in the special departments. Attached to the hospital is a large residential college with rooms for about sixty men, whilst for students who prefer to live in the suburbs, no other hospital is so conveniently placed, the railway accommodation being good and close at hand. There is now a complete School of Dental Surgery at this Institution, which is recognised by the Royal College of Surgeons of England, the facilities thus afforded of completing the whole course of dental study within the walls of one hospital will be appreciated by those intending to practise dentistry.

Appointments.—Eight house surgeons, eight house physicians, eight assistant house physicians, twenty-four assistant house surgeons, eight obstetric residents, twenty-four clinical assistants, and ninety-six dressers are selected annually from the students according to merit, and without payment. There are also a large number of junior appointments, every part of the hospital practice being systematically employed for instruction.

Scholarships.—Open scholarships of £100 or £50 in classics, mathematics, and modern languages. Open scholarships of £150 and £60 in chemistry, physics, and biology, and an open scholarship of £50 for University students in two of the following subjects:—Anatomy, physiology, organic chemistry, zoology, physics. Six scholarships, varying in value from £13 to £25 each, for general proficiency in medical study, open to students of different years. The Treasurer's gold medal in medicine; the Treasurer's gold medal in surgery; the Sands Cox scholarship of £15 per annum for three years for physiology; the Michael Harris prize of £10 for anatomy; Beaney prize in pathology, 30 guineas; the Beaney scholarship in materia medica, 30 guineas; the Golding-Bird gold medal and scholarship (£20); and the Gull Research scholarship of £150 per annum. The Physical Society awards two prizes, each of £5, to the authors of the best essays on selected subjects, prizes of £10 and £5 for the best papers read before the Society, and a prize of £5 to the member who has most distinguished himself in the debates of the session.

New School Buildings.—A considerable addition to the school buildings was opened in 1897, comprising a series of class-rooms, laboratories, and a lecture theatre for the teaching of physiology.

Fees.—For the entire course of lectures and hospital practice, 150 guineas, if paid in one sum on entrance; or payment may be made by four instalments of 40 guineas each, payable at the beginning of the first, second, third, and fourth years respectively.

King's College Hospital.—This hospital is centrally situated, being contiguous to the Royal College of Surgeons, Lincoln's Inn Fields. The College adjoins Somerset House and is close to the hospital, in which there are 220 beds available for clinical teaching; ophthalmic, ear, throat, skin, and dental departments are attached to the hospital. Some wards are specially devoted to children's diseases. The wards have been recently refloored and the electric light installed throughout.

Scholarships.—£800 are awarded annually in scholarships and prizes. At entrance two science exhibitions of £60 and £40 value are open to all candidates under the age of nineteen; two scholarships of the value of £75 each (subjects literary), and two exhibitions of the value of £60 and £40 each (subjects scientific) are open to students commencing their curriculum. Two scholarships, value 70 and 60 guineas, are open to students of a British University who come up to London to complete their curriculum; two junior scholarships of £20 each for first year students, one of £30 for second year students, one of £50 for third year students in residence, and one of £40 for fourth year students. In addition students may compete for the Daniell scholarship, value £40; the Warneford prizes, value £40; the Rabbeth scholarship, value £20; the Carter, Todd, Jelf, Tanner, Leathes prizes, and all class and clinical prizes.

Appointments.—Medical and surgical Sambrooke registrarships, tenable for two years, each £50 per annum. Resident hospital appointments, viz., senior and junior house physicians, assistant house physician, physician accoucheur's assistant and assistant house accoucheur, and three house surgeons with free board and residence at the hospital; and senior and junior clinical assistants in special departments.

University of London.—Special courses of lectures and practical instruction in the chemical, physical, and physiological laboratories have been arranged for students preparing for preliminary scientific and intermediate science examinations of the University of London.

F.R.C.S. Examinations.—Special classes are arranged for the final F.R.C.S. examinations. Further particulars can be obtained from the Dean.

London Hospital.—This hospital is the largest in England, containing as it does, 800 beds. It has, moreover, wards and a teaching staff for almost every special department in the domain of medicine: the scholarships and prizes are many and valuable, and both school and staff are deservedly popular with students.

Scholarships and Prizes.—At Entrance.—Price scholarship in science, £120; Price scholarship in anatomy and physiology, £60; entrance scholarships in science, £60 and £35; Epsom scholarship, £126; Buxton scholarships in arts, £30 and £20. After Entrance.—Anatomy and biology scholarship, £20; anatomy and physiology scholarship, £95; Letheby prize, senior, £20; Letheby prize, junior, £10; scholarship in clinical medicine, £20; scholarship in clinical surgery, £20; scholarship in clinical obstetrics, £20; Duckworth Nelson prize, £10; Hutchinson prize, £35; Sutton prize, £20; Sir Andrew Clark prize, £26; Anderson prize, £9; Out-patient dressers' prizes, £60; practical anatomy prizes, £10.

Appointments.—The "House" appointments, which are more numerous than at any other hospital in the Kingdom, are made without fee of any kind, and all resident officers are provided with free board and rooms, and in some instances with salary also.

The additional buildings for the department of public health, for the biological, chemical, and physical laboratories, materia medica museum, &c., and the new bacteriological department with general laboratory, research laboratories, class rooms for D.P.H. work, sterilising room, animal room, &c., are now open. For all these departments special teachers have already been appointed, who are devoting their entire time to the particular subjects that they have undertaken. In addition to these alterations and additions, arrangements have been made in the hospital for additional clinical teaching.

Fees.—Perpetual fee for lectures, demonstrations, and Hospital Practice, payable in three instalments of 45, 45, and 40 guineas at the commencement of the first, second,'and third years respectively, 130 guineas; or, if in one payment, 120 guineas. A reduction of 8 guineas for chemistry and physics, and 5 guineas for elementary biology is made from the above fees, in the case of students who have passed in these subjects at the First Conjoint Examination before entering the College. Fee for students entering in their third year (their first and second years having been spent at a recognised medical school elsewhere), 60 guineas. (This fee is payable by students entering who have passed the first M.B. Oxford; the second M.B. Cambridge; or the Intermediate M.B. London.) Dental students (general hospital practice and lectures), 40 guineas. General fee for dental practice, 10 guineas.

Note.—A reduction of 15 guineas will be allowed to the sons of medical men from the perpetual fee if paid in full, or 5 guineas from each instalment.

Special entries can be made either for single courses of lectures or for hospital practice.

Accommodation is obtainable at a very reasonable rate close by, or in the suburbs a few minutes' distant by train. Dinners and luncheons are provided in the Students' Club, which, with the reading and smoking rooms, now form part of the college buildings. The "London Hospitals' Club Union" has a field for cricket, football, &c., with an excellent pavilion, at Hale End. The clubs and societies are open to all the students, and are warmly encouraged by the staff. The new club rooms, gardens, and forecourt are now open. Full particulars of the Warden, Mr. Munro Scott.

St. Mary's Hospital.—This hospital is situated at Paddington, near the terminus of the Great Western Railway, and at present contains 281 beds. Fresh laboratories, fitted with electric light and all modern improvements, for the study of pathology and bacteriology, have recently been added, and also a new physiological lecture-room. A special department of pathological chemistry has been instituted. The new wing, the ground-floor of which, comprising the new out-patient department, was opened in 1898, is now in process of completion. This will add to the hospital eighty-one new beds, and will include additional operating theatres, a new clinical laboratory, a clinical theatre, and an X-ray department.

Appointments.—All clinical appointments in the Hospital are free to students of the Medical School, and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, four obstetric officers, and two resident anæsthetists are appointed in each year, and receive board and residence in the Hospital.

Scholarships, &c.—One scholarship in natural science, of the value of £145, open to any gentleman who has not completed a winter session of study at a medical school. Two scholarships in natural science, each of the value of £78 15s., and one of £52 10s., under the same conditions. Two scholarships, each of 60 guineas, open to students from the Universities of Oxford and Cambridge. The scholarships will be awarded by examination on September 23rd and 24th.

Fees.—Fee for attendance on the full five years' curriculum of hospital practice and all lectures, demonstrations, and special tutorial classes, including membership of the Library, Medical Society, Students' Club, and all the athletic clubs, and the receipt of the hospital Gazette for five years, £140, paid in one sum on entering the school; or in instalments, £145

Students who have completed their examinations in anatomy and physiology at the Universities of Oxford, Cambridge, or other University, are admitted as perpetual pupils on payment of a fee of 60 guineas in one sum, or 65 guineas in two annual instalments. University students, prior to completing the anatomy and physiology examinations, pay an annual fee of 25 guineas. After completing the anatomy and physiology examinations, the inclusive fee may be paid.

Preliminary Scientific Course.—Special classes, including lectures and laboratory work, are held throughout the year.

Middlesex Hospital.—This hospital, which is conveniently situated in the centre both of business and residential London, contains 330 beds. There are special departments for cancer, and for ophthalmic, throat, aural, skin, dental, and children's diseases. Wards are also devoted to cases of uterine disease and of syphilis. The new school buildings are now in regular use. Residence for students is obtainable in the residential college, which has its frontage on the hospital garden.

Appointments.—Casualty surgical officer, casualty medical officer, six house surgeons, six house physicians, and two resident obstetric physicians. The above officers have residence and board in the college free of expense. Clinical clerks and dressers in all the departments are also appointed in addition to the foregoing.

Scholarships, &c.—Two entrance scholarships of the value of £100 and £60 respectively. One entrance scholarship of the value of £60, open to Oxford and Cambridge students only. (Subjects—Anatomy and physiology, including histology.) Two Broderip scholarships of £60 and £40 respectively, for medicine and surgery; John Murray medal and scholarship, awarded every third year; the Governor's prize of £21 for students in their final year. Hetley clinical prize, value £25, awarded annually for proficiency in practical clinical medicine, surgery, and obstetrics; the Lyell Gold Medal in surgery and surgical anatomy; the Leopold Hudson prize, value 11 guineas, in surgical pathology, including bacteriology; Freeman scholarship, £30, in obstetrics and gynæcology; exhibitions of 10 guineas and 5 guineas for anatomy and physiology to second and first year's students respectively, as well as class prizes in all subjects.

Fees.—General fee for the entire course of hospital practice and lectures, 135 guineas, if paid in one sum on entrance, or by instalments of 60, 50, and 35 guineas, payable at the commencement of the first, second, and third years respectively. General fee for members of a university who have completed one year of medical study, 90 guineas, if paid in one sum, or by instalments of 60 and 40 guineas. For those who have completed their anatomical and physiological studies the fee is 70 guineas on entrance, or in two instalments of 40 and 35 guineas. The composition fee for London University students who have passed the preliminary science examination is 115 guineas. The fee for the curriculum for dental students is 54 guineas on entrance, or two instalments of 40 guineas and 20 guineas.

St. Thomas's Hospital.—This hospital, with its medical school attached, is one of the schools of the University of London. It is situated on the southern embankment of the Thames, facing the Houses of Parliament, and contains 602 beds. The school buildings, which are separated from the hospital by a quadrangle, comprise numerous theatres, laboratories, and class rooms, which are well adapted for the modern teaching of large bodies of students in all subjects of the medical curriculum. There is a large library and reading room, and a very complete museum and gymnasium. A ground of more than nine acres in extent is provided at Chiswick for out-door sports.

A clinical laboratory is provided, in which all the more difficult methods of diagnosis, bacteriological, chemical, and microscopical, are carried on under the direction of a superintendent. The department for out-patients has been re-arranged, so that large numbers of students are enabled to follow closely the practice and teaching of the assistant staff. To this department there has been added a completely fitted operating room.

Appointments are open to all students. A resident assistant physician and a resident assistant surgeon are appointed annually at a salary of £100 with board and lodging. Two hospital registrars, at an annual salary of £100 each, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. An obstetric tutor and registrar is appointed each year at an annual salary of £50. Four house physicians, two assistant house physicians, four house surgeons, four assistant house surgeons, two obstetric house physicians, two ophthalmic house surgeons, and eight clinical assistants in the special departments are appointed every three months.

Scholarships, Prizes, &c.—Three entrance scholarships are offered for competition in September, viz., one of 150 guineas and one of £60 in chemistry and physics, with either physiology, botany, or zoology at the option of candidates, for first year's students; one of £50 open to University students who have passed in anatomy, physiology, materia medica, and pharmacy for a medical degree in any of the Universities of the United Kingdom, and have not entered as students in any London medical school. Copies of the examination papers of last year may be obtained on application to the medical secretary. Applications must be sent in not later than September 17th, with certificate of birth and of preliminary examination, and with a notification as to the optional subject chosen. Numerous scholarships, prizes, and medals are open to competition throughout the whole career of a student, including a Fellowship of £100 given by the Salters' Company for research in pharmacology.

Fees.—The fees may be paid in one sum or by instalments. Entries may be made separately to lectures or to hospital practice. Special arrangements are made for students from the Universities and elsewhere entering in their second or subsequent years, also for dental students and for qualified practitioners.

Special classes for the Preliminary Scientific and Intermed., M.B.Lond., for the Oxford and Cambridge examinations, and for the Primary and Final F.R.C.S., are held throughout the year.

A register of approved lodgings is kept by the medical secretary, who has a list of local medical practitioners and others who receive students into their houses. The prospectus of the school, containing full particulars as to fees, course of study advised, &c., and all necessary information, may be obtained on application to Mr. Rendle, the medical secretary.

University College Hospital.—This hospital is situated in Gower Street, not far from Euston Railway terminus. The college where the classes are held faces the hospital, on the opposite side of the street. The number of beds available for teaching purposes is 188.

Appointments.—Eight house physicians, six house surgeons, four senior and four junior obstetric assistants, and two ophthalmic assistants, are selected annually by examination from among the senior students, without fee. The house physicians and house surgeons reside in the hospital for a period of six months, and the senior obstetric assistants for three months, and receive their board and lodging free.

The offices of out-patient physicians' and surgeons' assistants, clinical clerks, surgeons' dressers, and ophthalmic surgeons' assistants are filled by pupils who are also students of the college, without additional fee.

Scholarships, &c.—Entrance scholarships: One of the value of £120, and two of 60 guineas for proficiency in science, the subjects being those of the Preliminary Scientific Examination of the University of London, and two of 80 guineas each, the subjects being anatomy and physiology; the Atkinson-Morley surgical scholarship of £45 a year, tenable for three years; Atchison's scholarship, value £55, tenable for two years; Sharpey physiological scholarship, value about £105 a year, tenable for three years; Filliter exhibition for proficiency in pathological anatomy, value £30; Erichsen prize, operating case, value £10 10s., awarded for practical surgery, Dr. Fellow's clinical medals, the Liston gold medal, Alexander Bruce gold medal, Cluff memorial prize, Tuke medals for pathology, class medals, &c., gold and silver medals or other prizes, as well as certificates of honour, are awarded after competitive examinations in particular branches of study. The Tuffnell scholarship of £80 for chemistry, two years', and the Clothworker's exhibitions in chemistry and physics of £30 each, can also be held in the medical faculty.

Fees.—The following have been grouped to meet the requirements of the various examining boards: 2. For the medical examination required by the Examining Board in England and the Society of Apothecaries: 150 guineas, if paid in one sum at the commencement of the course; 155 guineas if paid by instalments. 2. For those students who do not require to attend chemistry, pharmacy, and elementary biology at a medical school (under the regulations of the examining board in England) the fee is: 135 guineas if paid in one sum; 140 guineas if paid by instalments. 3. For the courses necessary for the Preliminary Scientific Examinations of the University of London, 25 guineas. 4. For the course of instruction for the Intermediate Examination in Medicine of the University of London, 60 guineas paid in one sum. 5. For the course of instruction for the final M.B. examination of the University of London, 80 guineas if paid in one sum; 82 guineas if paid by instalments. This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, and Durham. 6. Composition fee for dental students, for the courses required for the L.D.S., 65 guineas or exclusive of chemistry, practical chemistry, physics, and materia medica, 50 guineas. The composition fees, 1, 2, 4 and 5, admit to attendance on systematic lectures and to hospital practice, where this is included in the fee, during five years.

Westminster Hospital.—This hospital is conveniently situated, facing the Abbey, and is readily accessible from all parts of the metropolis. It contains 205 beds for general cases, and all the special departments. New school buildings have been erected close by which afford accommodation for 150 students. The class rooms, dissecting rooms, and lecture theatre are excellent samples of modern erections, affording ample scope for study.

Appointments.—Medical and surgical registrars, each £40 per annum; two house physicians, two house surgeons, two assistant house surgeons, and resident obstetric assistant. These officers, except the two first named, are all boarded free of expense Fourth year's students are appointed to be clinical assistants in the various departments.

Scholarships, &c.—(*a*) Winter Session—The Guthrie scholarship £60, entrance scholarship £40, entrance scholarship £30, dental scholarship £20; subjects, Latin, mathematics, experimental physics, chemistry, and either Greek, French, or German. University scholarships, £40 and £30, subjects, anatomy and physiology. Natural science scholarship, £60, same as for Prel. Sci. of University of London. Natural science scholarship, £40, chemistry and physics. Free presentation, open to pupils of Epsom Medical College. (*b*) Summer Session.—Natural science scholarship, £60, same as winter. Natural science scholarship, £40, same as above. Arts scholarship, £60, arts scholarship, £40, University scholarships, £40 and £30, subjects same as in winter session. (*c*) Prizes.—Treasurers', 10 guineas, for first year's men; Chadwick, 20 guineas for students of any year not exceeding fifth. To be competed for by unqualified men. Bird medal and prize, £14, for students who have completed fourth winter session. Sturges prize in clinical medicine £8, clinical surgery prize £5 to be competed for by unqualified men. And class prizes in the various subjects.

Fees.—In one payment of 110 guineas, or two payments of 60 guineas each, payable on entrance, and at the commencement of second year respectively, or by six payments distributed over six sessions of 25 guineas and 20 guineas alternately. Fees for shorter periods or for single courses may be learned on application to the Dean. Fees for dental students, payable in one sum on entrance, 50 guineas, or in two instalments of £27 10s.

London School of Medicine for Women (**Royal Free Hospital**).—This school, which is situated in Hunter Street, Brunswick Square, opens at the same time as, and the periods of study, lectures, &c., are similar to those at the ordinary medical schools. A dissecting-room, physiological, chemical, biological, physical, and pharmaceutical laboratories, and library are provided at the School, and clinical lectures are regularly delivered at the Royal Free Hospital close by, which institution is appropriated to the students at the School as a field of practical study; clerkships, dresserships, and two of the resident posts being tenable there without fee by women. Numerous scholarships and prizes are awarded, particulars of which can be obtained on application.

Fees.—The fee for the ordinary curriculum of school lectures is £90 if paid in one sum, or £95 if paid in instalments. The fee for clinical teaching is £35, or £40 if paid in instalments.

Special Classes for the Preliminary Scientific Examination of the University of London. For the whole course, 20 guineas.

EXTRA-ACADEMICAL INSTITUTIONS IN LONDON.

Cooke's Medical School.—This school is prepared to admit to its supplementary work all who may wish to join the same, but in regard to its curriculum work it does not receive more than half a-dozen students in the course of the year; these have special advantages both as regards anatomy and physiology, at charges but slightly in excess of current rates. By decision of various examining bodies gentlemen rejected at their anatomical and physiological examinations can get signed up for the supplementary work they are required to put in before re-examination. The school is also recognised for the special dissections for the Fellowship of the Royal College of Surgeons. The surgical operations are performed on the dead body, and these courses are recognised for army examinations, the Indian Medical Service, &c. The school possesses a good collection of physiological and chemical apparatus, and gentlemen preparing for the higher examinations, the F.R.C.S.Eng., M.B.London, Cambridge, Oxford, &c., receive special instruction in the more difficult subjects by separate classes.

London School of Dental Surgery.—This institution is the oldest of the Dental Colleges in the United Kingdom, and its teaching is recognised by the Royal College of Surgeons for the dental diploma. It is centrally situated in Leicester Square, is open daily, and under the supervision of a special staff and house surgeon. The mechanical laboratory is the most perfect of its kind, and its usefulness can hardly be overestimated. The Hospital, having been rebuilt recently, the accommodation is equal to all requirements. Demonstrators have been appointed to instruct the new students in the elements of operative dental surgery, and at the beginning of the session each demonstrator gives a course of lecture on this subject. There is the Saunders Scholarship and Walker Scholarship (entrance) value £20 each, awarded yearly, the Storer Bennett Research Scholarship, value £50, awarded triennially, and the eight house surgeoncies are filled by students of the hospital holding the L.D.S. Fee for two years' hospital practice required by the curriculum, including lectures, £50. The fee for three years' tuition in mechanical dentistry is 150 guineas.

National Dental Hospital.—This institution is situated near the border of North-West London (Great Portland Street, W.), and the same teaching faciliites and hospital practice are obtainable here as at the foregoing institution, special demonstrations being given by members of the staff There are also a mechanical laboratory, bacteriological laboratory, museum, students' common room, a metallurgical laboratory, extraction and stopping rooms, lecture hall, regulations room, &c., all lighted by electricity, and warmed and ventilated after the most approved requirements: in fact, this institution may be pronounced a model dental hospital and school. The winter session commences at the same time as at the medical schools, on October 1st. The medical tutors hold special classes before each College examination. The prizes include one entrance exhibition, value £15, and the Rymer prize of £5 5s. The fee for two years' hospital practice required by the curriculum including lectures, is £40.

London School of Tropical Medicine.—This institution is the outcome of a suggestion by the Right Hon.

Joseph Chamberlain, H.M. Secretary of State for the Colonies, and is situated at the Royal Victoria Docks, in connection with the Seaman's Hospital, than which no more suitable spot could be found, as ships arrive there in great numbers from the Tropics, affording immediate opportunity for the treatment of patients and for the study of tropical diseases. The school buildings are placed within the hospital grounds, and systematic courses of instruction are obtainable from duly authorised teachers throughout the year. Students also have the privilege of attending the medical and surgical practice at the Dreadnought Hospital, Greenwich. Information as to fees, &c., can be obtained of the Dean or the Secretary.

Medical students are admitted to the practice of the following metropolitan hospitals, to which no medical school is attached. Detailed particulars will be supplied on application to the various secretaries.

West London Hospital, Hammersmith.—This contains over 160 beds, and has an extensive out-patient department. Dresserships and clinical clerkships may be obtained. Two house surgeons and two house physicians are selected every six months. Special departments have recently been opened for diseases of the throat, ear, skin, and deformities. An electrical department has also been added.

Great Northern Central Hospital, Holloway Road, N.—This institution has been recently enlarged, and now contains 159 beds. The practice of the hospital is open to practitioners and senior students, and clinical and pathological assistants are appointed in the wards and out-patient departments, as in the larger general hospitals.

Bethlem Royal Hospital.—Two resident house physicians who have recently obtained their diplomas to practise medicine and surgery, are elected every six months, and are provided with apartments, complete board, attendance, washing, and an honorarium of 25 guineas per quarter. The students of certain specified London medical schools receive clinical instruction in the wards of the hospital, and qualified practitioners may attend for a period of three months on payment of a fee.

National Hospital for Epilepsy and other Diseases of the Nervous System, Queen's Square, W.C.—Contains 200 beds. It has on its staff men of European reputation, and the institution is recognised by the Conjoint Board where part of the fifth year of study may be devoted to clinical work. Clinical clerks are appointed to the physicians for out-patients, and courses of lectures and clinical demonstrations are given each year.

Hospital for Consumption and Diseases of the Chest, Brompton.—The largest institution for the treatment of affections of the chest in the United Kingdom, there being 320 beds in the two buildings. There are four house physicians, who reside in the hospital, each for a period of six months. Lectures and demonstrations are given by members of the medical staff on Wednesdays and Fridays at four o'clock, save during the vacations. Terms, £3 3s. for three months; six months, £5 5s.; perpetual, £10 10s.

City of London Hospital for Diseases of the Chest, Victoria Park.—This is a large and well-equipped hospital at the East End, containing 164 beds. Clinical lectures and demonstrations are given by the members of an exceptionally experienced staff. Fee for three months' attendance on hospital practice, 2 guineas; six months, 3 guineas.

Throat and Ear Hospitals.

Central London Throat, Nose, and Ear Hospital, Gray's Inn Road, contains seventeen beds, with an extensive out-patient department recently enlarged. Clinical demonstrations and instruction to qualified practitioners and senior students daily during the hours of the surgeon's visits. Twelve clinical assistants who must be duly qualified are elected to assist the surgeons. Operation days—In-patients, Tuesdays, 2.15 p.m.; out-patients, Tuesdays and Fridays, 2 p.m. Fees for the three months' attendance, £3 3s.; six months', £5 5s. Full details of this institution will be found on reference to our advertising columns.

Hospital for Diseases of the Throat and Chest, Golden Square, W., with branches at Newington, Walworth and Notting Hill, contains 50 beds. Students are admitted to hospital practice on payment of fee of three months' course, £3 3s.; for six months, £5 5s.; perpetual, £7 7s.

Women and Children.

The Hospital for Women, Soho Square.—The hospital contains 61 beds. In connection with this institution there is now an organised school of gynæcology, open to qualified medical men and to students after their third year. Clinical assistants to the physicians and surgeons in the in-patient and out-patient departments are appointed every three months. Fee for the three months' course, £5 5s.

The Samaritan Free Hospital for Women and Children, Lower Seymour Street, W., offers excellent opportunities for clinical study and training in the details of operative gynæcology. The success of the staff in this department have gained for them an European reputation. There are 47 beds.

Hospital for Sick Children, Great Ormond Street, Queen's Square, and Cromwell House, Highgate.—Fee for three months' attendance, £2 2s.; perpetual, £3 3s. There are now 200 beds, besides 52 additional at the convalescent branch, and it is probably the largest institution of the kind in the world. The practice of the hospital has been thrown open gratuitously to pupils of the different hospitals and medical schools of London, on conditions to be ascertained from the secretary.

Eye Hospitals.

Royal London Ophthalmic Hospital, formerly in Moorfields, was rebuilt three years ago in the City Road, is the largest hospital devoted to this specialty in Great Britain, and contains 138 beds. Students and practitioners are admitted to the practice daily at 9 o'clock. Operations, 10 o'clock and after. Fee for six months, £3 3s.; perpetual, £5 5s. Further particulars of the secretary.

Royal Westminster Ophthalmic Hospital, King William Street, Charing Cross, has about 34 beds and a very large out-patient clinique. The lectures and demonstrations are arranged with special reference to the requirements of practitioners and senior students. Fee, six months, £3 3s.; perpetual, £5 5s.

Royal Eye Hospital, St. George's Circus, Southwark.—There are 40 beds and two cots. Fees, £2 2s. for three months, £3 3s. for six months, and £5 5s. perpetual. Courses are held on ophthalmoscopy, refraction, and diseases of the eye; fee, £1 1s. for each course, but perpetual students may attend each course once without extra fee. Pathology class, £1 1s. extra to cover cost of materials.

Skin Hospitals.

St. John's Hospital for Diseases of the Skin.—Out-patient department, 49, Leicester Square; In-patient department, 238, Uxbridge Road. This hospital has a well-equipped in-patient department, with 50 beds. There is a School of Dermatology in connection with the hospital, which is conducted by the medical staff of the hospital. A spacious laboratory is also provided. During the past year the free course of Chesterfield Lectures given by Dr. Morgan Dockrell has proved a great success, being well attended by the profession. The next course (free) will commence in October next, and the dates and times will be duly announced in our columns. (See advt.)

One of the oldest institutions of the kind is the Western Skin Hospital (Welbeck St., W.), which was started as long ago as 1851. The practice of the hospital is open to students and practitioners. Students of this specialty have also the "London Skin Hospital," in Fitzroy Square, with seven beds and an out-patient department of over 1,400. There is also the Stamford Street

Skin Hospital, in the southern part of the metropolis, with 10 beds and an out-patient department of 5,600, so that the students' needs in this direction are well catered for.

St. Peter's Hospital for Stone.—This is the only special hospital for the treatment of stone and genito-urinary diseases in the United Kingdom. It contains 27 beds and one private ward, and has an excellent record. Students are admitted on the usual terms.

London Temperance Hospital.—The hospital contains 110 beds. The medical and surgical practice is open to students and practitioners. Appointments (vacancies for which are advertised in the medical journals): Surgical and medical registrars, resident medical officer, and one assistant resident medical officer.

Metropolitan Hospital, Kingsland.—This was until recently known as the Metropolitan Free Hospital, is situated in the north-eastern district of the metropolis, and contains 160 beds. It is a general hospital, with various special departments for the treatment of diseases of the eye, throat, ear, &c.

Tottenham Hospital, N.—This hospital contains medical and surgical wards and a ward for children, having in all 73 beds. There are special departments for gynæcological cases, diseases of the eye, ear, throat and nose, and skin diseases. It has now been authorised by the University of London to give certificates of post-graduate study for the M.D. and M.S. degrees.

METROPOLITAN POST-GRADUATE INSTITUTIONS.

Medical Graduates' College and Polyclinic.—This institution, of which Sir William Broadbent is the President, affords to medical men special facilities for acquiring technical skill, and advancing their medical and scientific knowledge. The building, which is large and commodious, is situated at 22, Chenies Street, Gower Street, and contains lecture and consulting rooms, pathological and clinical laboratories, Röntgen ray room, an ophthalmoscope room, a library and museum, and reading and smoking rooms. *Cliniques*, at which patients are shown, are given every day of the week except Saturday, at 4 p.m. Clinical lectures are delivered on alternate Wednesdays at 5.15 p.m., and systematic lectures on special subjects are delivered twice a month on Monday and Friday evenings at 5.15 p.m. Four sessions of practical classes, each lasting six weeks, and a vacation session of three weeks' duration are held during the year; the subjects taught comprising ophthalmology, otology, clinical microscopy, laryngology, applied anatomy, nervous diseases, and practical X-ray work. There are, in addition, extra-mural classes in operative surgery, bacteriology, and public health.

A complimentary ticket for three days, admitting to *cliniques* and lectures, is issued to any medical practitioner on personal application at the college. A monthly journal, *The Polyclinic* recording the work done in the college, is issued free to subscribers and members. The annual subscription for practitioners residing in Great Britain and Ireland is one guinea, and for practitioners non-resident in the United Kingdom half-a-guinea.

Full information may be obtained from the medical superintendent, Mr. Hayward Pinch, F.R.C.S., at 22, Chenies Street, Gower Street.

West London Post-Graduate College.—The West London Hospital Post-Graduate College was started in 1895. The hospital, which contains 175 beds, is in the main road, within two minutes' walk of the Hammersmith Stations of the Metropolitan, the District, and the South-Western Railways. The physicians and surgeons attend daily, at 2.30 p.m. Post-graduates accompany the staff on their visits to the wards. Instruction is given in the out-patient department daily, at 2.15 p.m., by assistant physicians and assistant surgeons.

There are special departments for diseases of the eye; the ear, throat, and nose; the skin; for diseases of women; medical diseases of children; and for orthopædic surgery and X-ray work. Clinical assistants are appointed from among the post-graduates. Practical classes for instruction in these subjects are held each session. Operations are performed daily.

Instruction is given in the administration of anæsthetics by the anæsthetists on the operating days. Special classes are held each session.

Post-mortem examinations are performed at 5 p.m., and demonstrations on recent pathological specimens are given on Mondays and Fridays during each session, at 11 a.m., in the lecture room.

Practical lectures and demonstrations are given each afternoon (except Saturday), at 5 p.m., during the session.

Fees.—The fee for the hospital practice, including all the ordinary demonstrations and lectures, is £1 1s. for one week; £2 2s. for one month; £4 4s. for three months: £6 6s. for six months; £9 9s. for one year; and £21 for a life ticket; all fees to be paid in advance.

A course of attendance on either the medical or surgical practice alone may be taken out for the fee of £3 3s. for three months. The fee for three months' attendance in any one special department, other than medicine or surgery, is £2 2s.

All information can be obtained on application to the Dean at the West London Hospital.

North-East London Post-Graduate College.—At the Tottenham Hospital, N., facilities are afforded to qualified medical men for taking part in the work of an active general hospital, and for attending demonstrations of various branches of medicine, surgery, and gynæcology, with opportunities for clinical instruction, diseases of the eye, ear, throat, nose, diseases of the skin, and dentistry. Clinical lectures are given from time to time by members of the staff. Cases are demonstrated both in the wards and in the various out-patient departments; operations are performed every afternoon of the week, except Saturday. The fee for a three months' course of study, which may be begun at any time, in any single department, is one guinea. A fee of two guineas admits to the whole practice of the hospital for a similar term, and a perpetual ticket for the practice of the hospital may, for the present, be obtained on payment of a fee of three guineas. Additional information can be obtained from the Dean of the Post-Graduate College, Dr. A. J. Whiting, 142, Harley Street, W.

PROVINCIAL MEDICAL SCHOOLS.

Bristol University College.—Faculty of Medicine.—The lectures and instruction given in the Faculty of Arts and Science of University College, Bristol, are adapted to the various preliminary examinations, and students can complete in Bristol the entire course of study required for the medical and surgical degrees of the University of London and the Royal College of Surgeons of England, and of the Apothecaries' Society of London, and for the examination of the Army and Navy Boards. Students of the college are admitted to the clinical practice of those very important and well-equipped institutions, the Bristol Royal Infirmary and the Bristol General Hospital. The infirmary and the hospital comprise between them a total of 470 beds, and both have very extensive out-patient departments. Special departments for the diseases of women and children, and of the eye, ear, and throat, besides large outdoor maternity departments and dental departments. Students of the college also have the privilege of attending the practice of the Bristol Royal Hospital for Sick Children and Women, containing 104 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore 614. Very exceptional facilities are thus offered to students for obtaining a wide and thorough acquaintance with all branches of medical and surgical work.

Appointments.—At the Royal Infirmary, and also at the General Hospital, clinical clerks and dressers reside in the house in weekly rotation. A pathological clerk is appointed every three months. Also obstetric clerks and ophthalmic dressers. Clinical lectures are given regularly at both institutions.

Scholarships, Prizes, &c.—Prizes and certificates of honour are given in University College in all the subjects of the curriculum, open only to perpetual students. There are two entrance scholarships, value £50 and £30 respectively, two Martyrs' memorial scholarships (pathology and morbid anatomy) of £10 each, the Tibbit's memorial prize, value £9, for proficiency in practical surgery, one gold and silver medal awarded by the committee, and various prizes for clinical work in surgery and medicine.

Fees.—School fees for attendance on all courses of lectures, except comparative anatomy, 65 guineas, or 55 guineas. Dental composition fee, 55 guineas. Clinical fees—Surgical practice, one year, 12 guineas; perpetual, 20 guineas. Medical practice, 20 guineas; perpetual medical and surgery, 35 guineas; clerk or dresser, 5 guineas; obstetric clerk, 3 guineas.

Prospectus and further information on application to the Dean, Professor E. Markham Skerritt.

Bristol Royal Infirmary.—This is one of the largest provincial hospitals in Great Britain, and contains 270 beds. It is provided with all the necessary appliances for a complete clinical education. The resident appointments are five in number, the two juniors of which are each tenable for six months, and are intended for qualified students of the infirmary who have previously acted as medical and surgical registrars. Several scholarships and prizes are obtainable. Fees for admission to the medical practice, six months, seven guineas; twelve months, 12 guineas; perpetual, 20 guineas. The same fees are payable for surgical practice. Perpetual fee for medical and surgical practice, 35 guineas. Dental practice, one year, £7 7s.; perpetual, £12 12s.

Yorkshire College School of Medicine, Leeds.—This school was originally founded seventy years since as the Leeds Medical School, but it now forms the medical department of Yorkshire College, one of the constituent colleges of the Victoria University. The building, erected on a site contiguous to the infirmary, and opened five years ago, contains one of the finest dissecting rooms in the kingdom, extensive laboratories for physiology and pathology, with the most recent improvements in fittings and apparatus, ample lecture-room accommodation, a large library, and separate museums for pathology and anatomy. Professors and lecturers are attached, and the clinical teaching is given by the physicians and surgeons attached to the infirmary. Ophthalmic demonstrations and demonstrations of skin diseases are given in the infirmary by surgeons in each department, where also are obtainable various clinical clerkships, dresserships, and other appointments; and an extern maternity charity is attached, at which the necessary attendance at labours can be taken: besides the infirmary there are a large dispensary, a large hospital for infectious diseases, and a hospital for women and children, all of which are open to students of the school.

Students here have also excellent opportunities of acquiring a thorough insight into psychological medicine, as the renowned West Riding Lunatic Asylum is in connection, whereat lectures on mental diseases are delivered during the summer.

Scholarships, Prizes, &c.—(1) A Gilchrist scholarship of £50 a year for three years is awarded annually to the candidate who stands highest at the June Preliminary Examination at the Victoria University, provided he passes in the first division. (2) A university scholarship of £25 is awarded annually on the results of the second examination for the degree of M.B. and B.Ch., held in March. (3) An entrance scholarship of 64 guineas (covering composition fee for a full curriculum of lectures) is offered every September to university students. There are also a Hardwick prize in clinical medicine, a M'Gill prize in clinical surgery, each of the value of £10, and Thorpe prizes of £10 and £5 in forensic medicine and hygiene, and a Scattergood prize in midwifery, besides silver and gold medals and other class prizes. The composition fee for attendance upon all the required courses of school lectures is 64 guineas for university students who have attended the preliminary scientific courses, and the same for non-university students, exclusive of chemistry and biology.

At the General Infirmary, containing 447 beds, the perpetual fee for medical and surgical practice and clinical lectures is £42 in one sum, or two instalments of £22 each. These fees are not included in the composition fees for lectures, and are payable separately.

A scholarship of £42 to cover the cost of medical and surgical practice is also offered annually by the Infirmary.

University College, Liverpool (Victoria University).—Medical Faculty.—The new Dissecting Room is on the upper floor, and measures 70 by 40 feet, and the Anatomical Museum occupies the room below. It is provided with a gallery on each side, and the excellent series of models, dissections, and preparations can now be properly displayed for the use of students.

A new chair of Bio-Chemistry has been founded by the generosity of Mr. William Johnston.

Royal Infirmary.—The Royal Infirmary, which adjoins the school, contains 300 beds, with forty special beds for the treatment of diseases of women. The Lying-in, Eye and Ear, Women's, Children's, Dental, and Skin hospitals are in the immediate vicinity, and their practice is open to the students of the Medical Faculty.

Fees.—The composition fees are: £24 15s. for preliminary scientific classes; £60 for the medical classes required for the Victoria, London, and other University degrees; £70 for all the classes required for the diplomas of the Conjoint Boards. The medical composition fees are payable in two instalments, at intervals of twelve months. The fee for hospital attendance at the Royal Infirmary is 40 guineas, also payable in two annual instalments.

Appointments.—Three house surgeons, three house physicians, and one external house surgeon to the Thornton Wards are appointed for six months, after (if necessary) competitive examination. Clinical clerks for each physician, dressers for each surgeon, and clerks to the Thornton Wards for diseases of women, are appointed every three months. Post-mortem clerks are appointed for six weeks. All students are required to perform this duty before the schedule for the Final Examination is signed.

Fellowships, scholarships, and prizes to the value of over £700 are awarded annually, details whereof will be furnished on application to the Dean.

Entrance Scholarships.—Four Robert Gee entrance scholarships, of the value each of £25 for one year, are offered annually for competition. The holder is required to take out the science course for the University degree in Medicine. Communications should be addressed to the Dean, Professor Paterson, M.D., University College, Liverpool.

Manchester.—Owens College School of Medicine, Victoria University.—The medical school buildings, which include large laboratories, dissecting-rooms, library and reading-rooms, are on the most modern principles, and students wishing to engage in anatomical, physiological, or pathological research will find excellent opportunity for study in the complete and well-furnished laboratories. Hospital practice is taken out at the Royal Infirmary, which contains 300 beds. The Cheadle Lunatic Asylum, St. Mary's Hospital, the Southern Hospital, and other special hospitals also afford teaching facilities of great importance.

Appointments.—The following appointments are made in connection with the Manchester Royal Infirmary:—Surgical registrar, at £80 per annum: a pathological registrar, at £100 per annum; a medical registrar, at £70 per annum; two assistant medical officers, each at £80 per annum; a resident medical officer at the Convalescent Hospital, Cheadle, one year, £150 per annum, resident medical officer, one year, £150; resident surgical officer, one year, £150 per annum; two chloroformists, annually, at £50; two house surgeons and one house physician are appointed every three months for a term of six months; a resident assistant at the Convalescent Hospital, Cheadle, appointed every six months.

Scholarships.—Dalton entrance scholarships, £40 per annum for two years; Cartwright entrance scholarship, £35 per annum for three years; Hulme entrance scholarship, £35 per annum for three years; Rogers entrance scholarship, £40 per annum for two years; Seaton entrance scholarship, £40 per annum for two years; James Gaskill entrance scholarship, £40 per annum for two years; Kay Shuttleworth (Sir Jas. Philips) scholarship, £30 per annum for three years; Theodore's modern languages exhibition, £15; Honorary Research Fellowships; Manchester Grammar School scholarship, £18 per annum for three years; Turner scholarship of £20 to students who have completed four years of study in the College; Platt physiological scholarship, value £50, tenable for two years, open to students between the ages of 18 and 25; one Professor Tom Jones exhibition in anatomy of £25; one Professor Tom Jones memorial surgical scholarship of £100, awarded triennially; two Platt exhibitions, £15 each, for first and second year's students in physiology; Sidney Renshaw physiological exhibition, £15; Dumville surgical prize, £15, at the end of the winter session; two Dauntsey medical entrance scholarships, value £35, tenable for one year; John Henry Agnew scholarship in diseases of children, value about £30, awarded annually; Gilchrist scholarships of £50 per annum tenable for three years in any of the Colleges of the Victoria University, awarded to the candidate gaining the highest number of marks in the first division of the preliminary examination of the Victoria University: the Bradley memorial scholarship, £20, in clinical surgery is offered annually in the summer session to candidates who must be fourth year students; one medical and one surgical clinical prize are also offered annually.

Fees.—Composition fee, £70, in two sums of £35 each. Hospital practice: composition fee, £42, or two instalments of £22 each.

Dental Fees.—Composition fee, £50, payable in two sums of £25 each. Hospital practice, £21.

University of Durham College of Medicine, Newcastle-on-Tyne.—A very commodious and ornate new building has been erected here at a cost of about £31,000. The Royal Infirmary, at which clinical instruction is obtained, contains 280 beds. Pathological demonstrations are given as opportunity offers. Practical midwifery can be studied at the Newcastle Lying-in Hospital. Opportunities for practical study are also afforded by the Dispensary, City Infectious Diseases Hospital, Eye Infirmary, Children's Hospital and at the Northumberland County Lunatic Asylum.

Appointments.—Assistant demonstrators of anatomy receiving each an honorarium; prosectors for the professor of anatomy, assistant demonstrators of physiology and pathology, assistants to the dental surgeon, clinical clerks, and dressers are appointed at regular intervals. One year's attendance at the College is required on the part of candidates for the degrees in medicine of the University of Dublin.

Scholarships, &c.—University scholarships, value £100, for proficiency in arts, awarded annually at the beginning of winter session to full students in their first year only. The Dickinson memorial scholarship (value, the interest of £400 with a gold medal) for medicine, surgery, midwifery, and pathology, open to full students who have passed the primary examination of a licensing body. The Tulloch scholarship, interest of £400 annually, for anatomy, physiology, and chemistry. The Charlton memorial scholarship, interest of £700 annually, open to full students entered for the class of medicine at end of the fourth or fifth winter. The Gibb scholarship, interest of £500 annually, for pathology, at end of summer session. Goyder memorial scholarship in clinical medicine and clinical surgery, proceeds of £325 annually. The Luke Armstrong memorial scholarship, interest on £680. The Stephen Scott scholarship in surgery, interest on £1,000. The Heath scholarship in surgery (the next award will be in 1902); the interest on £4,000 is awarded every second year. The Gibson prize in midwifery and diseases of women and children; the interest on £225 is awarded yearly. At the end of each session a prize of books is awarded in each of the regular classes.

Fees.—(*a*) A composition ticket for lectures at the college may be obtained.—1. By payment of 70 guineas on entrance. 2. By payment of 45 guineas at the commencement of the first sessional year and 35 guineas at the commencement of the second sessional year. 3. By three annual instalments of 35, 30, and 20 guineas, respectively, at the commencement of the sessional year. (*b*) Fees for attendance on hospital practice: For three months' medical and hospital practice, five guineas; for six months, eight guineas; for one year, 12 guineas; perpetual, 25 guineas; or by three instalments at the commencement of the sessional year, viz., first year, 12 guineas; second year, 10 guineas; third year, six guineas; or by two instalments, viz., first year, 14 guineas; second year, 12 guineas.

Liverpool Dental Hospital and School of Dental Surgery.—The courses of systematic instruction are given in University College, five minutes' walk from the Dental Hospital. The two institutions are now closely associated, and the management of the curriculum is in the hands of a joint committee.

The staff of the Dental Hospital includes seven honorary dental surgeons, a demonstrator, two house surgeons, and a curator. Fees for two years' hospital practice, £21. Apprenticeship: A limited number of apprentices are admitted annually; fees for three years, £105. Further information may be had from the Warden, Mr. W. H. Gilmour. The various medical and dental lectures are given at University College.

Fees.—The composition fee for all lectures is £50, in one payment on entrance, or in two equal instalments (one half on entrance, and the remainder within twelve months). The fee for general hospital practice is £10 10s.

The winter session will begin on Wednesday, October 1st. Prospectuses and further information may be had on application to the Secretary, University College, Liverpool. (See also under "English Universities.")

Sheffield University College Medical Department.—The medical department contains a medical library, good class-rooms, an excellent anatomical department, and every provision for medical education under the most modern principles. The physiological department has been entirely reconstructed and equipped in memory of the late president of the school, Mr. Wm. F. Favell, through the generosity of anonymous donors. The department consists of a lecture and demonstration theatre, students' laboratory, preparing room and galvanometer room, all of which are equipped with the most modern apparatus. New premises have been acquired near the College for the pathological museum and laboratory, and also for a bacteriological laboratory, which has been completely equipped through the generosity of "A Sheffield Citizen." The course of lectures and instruction is adapted to meet the requirements of the various examining bodies. Full courses of instruction required for the D.P.H. are given. The new dental department has been recognised by the examining bodies. Students at this college obtain medical and surgical practice at the Royal Infirmary, a well-appointed institution, containing 247 beds, and also at the Sheffield Royal Hospital, containing 160 beds. The fees for attendance, £6 6s. each for medical and surgical practice during the winter session, and for three months £3 3s. each. Perpetual fee for medical and surgical hospital practice in a single payment of £45, or in two payments, viz., £26 on entrance, and £22 within twelve months afterwards. Students are also admitted to the practice of the Jessop Hospital for Diseases of Women, to the City Fever Hospitals, and to the South Yorkshire Lunatic Asylum at Wadsley. The winter session will commence on October 1st, when the introductory address will be delivered by Sir H. G. Howse.

Scholarships, &c.—An entrance scholarship of the value of £110 is annually awarded to the best candidate (if of sufficient merit) in mathematics, elementary physics, inorganic chemistry, Latin, English.

Composition fee, 60 guineas, or in two instalments of 35 guineas and 30 guineas, for lectures and practical classes required by the Examining Board in England.

The Kaye scholarship, for second year's students, natives of Sheffield, is awarded annually, under certain regulations. Prizes for clinical medicine and clinical surgery of 10 guineas; Simon prize in pathology, £10; prizes in books and certificates awarded annually.

University College, Cardiff, School of Medicine.—This college, which is one of the colleges of the University of Wales, has since its foundation, in 1883, prepared students for the Preliminary Scientific examination of the University of London, and for the corresponding examinations of other licensing bodies. In 1893 Chairs of Anatomy and Physiology and a Lectureship in Materia Medica and Pharmacy were established, making it possible for students of medicine to spend three out of the five years of prescribed study at Cardiff. Arrangements with the managing committee of the Cardiff Infirmary give students of the College the privilege of attending this large and well-ordered hospital, which is situated within five minutes' walk of University College. Many students, especially from Wales and Monmouthshire, avail themselves of the opportunities thus afforded to pursue the earlier part of the medical curriculum near home. All classes are open alike to both men and women students over sixteen years of age. The courses of instruction given at Cardiff are recognised as qualifying for the examinations of the universities, Royal colleges, and other licensing bodies of Great Britain and Ireland. Having spent two or three years in study at Cardiff, and having passed the corresponding examinations, a student may proceed to London or elsewhere and complete his qualifying course for a university degree or for a college diploma.

Students preparing for the first and second examinations of the Conjoint Board for England or for the corresponding examinations of the Conjoint Board for Scotland, or for those of the Society of Apothecaries, may compound for their classes by paying a single composition fee of £40, or by paying £18 10s. and £24 10s. at the beginning of their first and second years respectively.

Those preparing for the preliminary scientific and intermediate examination in medicine of the University of London may compound for their three years' instruction at Cardiff by paying a single composition fee of £57 10s., or by paying £13 13s., £28, and £21 at the beginning of their first, second and third years respectively.

In 1899 a department of Public Health was established, and lecturers in bacteriology and in public health and hygiene were appointed. Medical men preparing for a diploma in Public Health and Hygiene can attend complete courses of lectures and laboratory instruction in this department. These courses are recognised by the University of Cambridge, by the Royal Colleges of Physicians and Surgeons, and by Victoria University.

Scholarships, &c.—The attention of students about to matriculate is drawn to the numerous entrance scholarships for exhibitions which are offered at the college for competition in September, most of which may be held by medical students. Full particulars of the examination for these may be obtained from the Registrar.

LIVERPOOL ROYAL SOUTHERN HOSPITAL.—The clinical school of this hospital is situated within convenient distance of the school of medicine, and affords every facility for clinical and pathological study. The hospital contains 200 beds, and in addition to the general medical and surgical cases attention is devoted to the diseases of women and children. There is a special ward for tropical diseases in connection with the University College laboratories.

The medical and surgical staff visit the wards daily, and the ward instruction is supplemented by weekly clinical lectures. Additions have been made to the teaching staff so that students may now obtain instruction in diseases of the eye, ear and throat. Demonstrations in the use of the X-ray apparatus are given at intervals. There is an excellent pathological department, with laboratory attached, where demonstrations are arranged for and regular instruction is given in practical pathology. The practice of St. George's Hospital for Diseases of the Skin is free to students, and thus ample opportunity is afforded for acquiring a knowledge of dermatology. In addition to the clinical clerkships which are allotted to the students the resident posts of ambulance officers are given to the students whom the board may think most suited to hold them every three months. The Alexander Fellowship in Pathology of £100 a year is open to students of this school; three prizes of £5 each are also awarded to the gentlemen who present the best taken series of medical and surgical cases. Fees: Perpetual, £26 5s.; one year, £10 10s.; six months, £7 7s.; three months, £4 4s.

There are rooms for a limited number of resident students; terms (exclusive of fee for hospital practice), £15 15s. per quarter. The practice of the hospital is recognised by all examining bodies.

THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE.—This school was established in Liverpool in 1899. Sir Alfred Jones, K.C.M.G., is Chairman. It is in conjunction with the University College, Liverpool, and the Royal Southern Hospital, for the purposes of research and clinical teaching respectively. A special ward at the hospital has been set apart for the reception and treatment of tropical diseases, and all facilities for investigation and study are given in the Pathological Department of University College (Thompson Yates Laboratories).

Major Donald Ross, C.B., F.R.S., F.R.C.S., is the Walter Myers Lecturer in Tropical Medicine and Consulting Physician in Tropical Diseases at the hospital; Dr. H. E. Annet, Demonstrator in Tropical Medicine to the school; and Dr. R. Fielding Ould, Dr. A. S. Grunbaum, and Dr. Balfour Stewart, Assistant Lecturers. Dr. J. E. Dutton holds the Walter Myers Fellowship of Tropical Medicine. Mr. A. H. Milne, B.A., is the Honorary Secretary. Address, Chamber of Commerce, Liverpool.

The following are the principal provincial hospitals having the greatest number of beds, to which students are admitted where clinical instruction can be obtained, but to which there is no medical school attached:—

BATH ROYAL UNITED HOSPITAL.—This is a well-appointed hospital in the West of England, with 130 beds, at which students can obtain clinical instruction. The hospital is recognised by the Colleges, and is licensed for dissection. It contains also an excellent museum and library. Fee for six months' attendance, five guineas; twelve months' ten guineas.

BRADFORD INFIRMARY.—The hospital contains 230 beds. Non-resident pupils are received—and abundance of clinical material is obtainable. One year's attendance is recognised by the Examining Boards. Fee, perpetual, £10 10s.

BRIGHTON SUSSEX COUNTY HOSPITAL contains 190 beds. It is recognised by the College of Surgeons and by the Conjoint Board. Out-pupils are admitted to the clinical teaching and the classes at a fee of £21 for two years.

LIVERPOOL NORTHERN HOSPITAL, contains 155 beds. Clinical instruction is given by the staff during the summer and winter sessions. Clinical clerkships and dresserships are open to all students without additional fees. Fees for hospital attendance: Perpetual, £26 5s.; one year, £10 10s.; six months, £7 7s.; three months, £4 4s.; practical pharmacy, £2 2s.

NORFOLK AND NORWICH HOSPITAL.—This hospital is recognised by the Colleges, and contains 220 beds. Fees, £10 10s. for six months, £15 15s. for twelve months' medical and surgical practice. Pupils, resident and non-resident, are admitted.

NORTHAMPTON GENERAL INFIRMARY.—The number of beds is 163. Out-pupils are received, and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given in anatomy and materia medica and practical pharmacy. Non-resident pupils are taken at a fee of £10 10s.

ROYAL BERKSHIRE HOSPITAL.—The town of Reading, at which this hospital is situated, has a very large working-class population, and excellent opportunities for clinical instruction in the wards and extensive out-patient department are afforded here. It contains a splendid library, in which the Reading Pathological Society holds its meetings.

THE ROYAL HOSPITAL, Portsmouth.—The hospital is a preparatory school of medicine and surgery, and the attendance of pupils is recognised by the Examining Boards. The number of beds is 150, and during last year there were 1,303 in-patients and 9,191 out-patients.

Royal Devon and Exeter Hospital, Exeter.—The hospital contains 218 beds (including special children's wards), and has a good library, museum, dissecting room, and post-mortem room. Attendance on the practice of this hospital qualifies for all the Examining Boards. Arrangements can be made by which students can attend midwifery on application to the House Surgeon.

Wolverhampton General Hospital.—The hospital contains 230 beds, attendance at this hospital being recognised by all the Examining Boards. Pupils are trained in clinical work by the medical and surgical staff. Fees: Six months, £6 6s.; twelve months, £12 12s.; perpetual, £21.

THE ENGLISH UNIVERSITIES.

The English Universities are six in number, viz., Oxford, Cambridge, London, the Victoria, Durham, and the recently created University of Birmingham. The choice of a university is usually determined by social, geographical, and financial considerations. Evidently students whose parents are able and willing to incur the necessary expense would do well to select one or other of the ancient universities, since their degrees confer upon their holders a status not accorded by the public to the degrees of more modern educational institutions. To those less favoured by fortune, but blessed with energy and a fair share of intelligence, the London University offers ample scope, and its degrees are recognised as the outward and visible sign of high professional attainments. The Victoria University comprises Owens College, Manchester, University College, Liverpool, and the Yorkshire College, at Leeds. It thus covers a wide area and attracts considerable numbers of students whose aim is the possession of a degree in medicine.

OXFORD.

There are two degrees in medicine, M.B. and M.D., and two degrees in surgery, B.Ch. and M.Ch. The M.B. and B.Ch. degrees are granted to those members of the University who have passed the second examination. Graduates in Arts, B.A., are alone eligible for these two degrees. In order to obtain the degree of M.B. and B.Ch., the following examinations must be passed:—1. Preliminary subjects: Mechanics and physics, chemistry, animal morphology and botany. 2. Professional (*a*) First Examination (held twice a year): Subjects: Organic chemistry, unless the candidate has obtained a first or second class in chemistry in the Natural Science School; Human physiology, unless he has obtained a first or second class in animal physiology in the Natural Science School; Human anatomy and Materia medica with Pharmacy. (*b*) Second Examination: Subjects: Medicine, Surgery, Midwifery, Pathology, Forensic medicine with Hygiene. The approximate dates of the examinations are as follows.—Preliminaries — Mechanics, physics, and chemistry, December and June; Animal morphology and botany, December and March; Professional (First and Second M.B.), June and December.

The degree of M.D. is granted to Bachelors of Medicine of the University who have entered on their thirty-ninth term on their presenting a dissertation approved by the appointed professors and examiners.

The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term, who are members of the surgical staff of a recognised hospital, or have acted as dresser or house surgeon in such a hospital for six months, and who have passed an examination in surgery, surgical anatomy, and surgical operations. This examination is held annually, in June, at the end of the Second M.B. Examination.

The First Examination for the degrees of M.B. and B.Ch. may be passed as soon as the Preliminary Scientific examinations have been completed. The subjects of this examination may be presented separately or in any combination or in any order, provided anatomy and physiology be passed together.

The Second Examination may be passed at any time after the completion of the first. The subjects of medicine, surgery, and midwifery must be passed at the same examination, but candidates are allowed to present themselves in pathology at a separate examination.

Diploma in Public Health.—An examination is held yearly in Michaelmas Term, open to all registered medical practitioners. No one is admitted as a candidate unless his name has been on the "Medical Register" for twelve months.

Scholarships, &c.—Scholarships in some branch of Natural science (chemistry, physics, biology) of the average value of £80 per annum, tenable for four years and renewable under certain conditions for a fifth year, as well as exhibitions of less annual value, are awarded after competitive examinations every year by some of the Colleges. Notices of vacancy, &c., are published in the "University Gazette." In February there is competed for annually, by those who, having obtained a first-class in any school (moderations or final), or a scholarship or prize open to general competition in the University, have passed all the examinations for the degree of B.A. A Radcliffe Travelling Fellowship is tenable for three years, of the annual value of £200. The examination is partly scientific, partly medical. A Rolleston Memorial prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some biological subject including physiology or pathology.

More detailed information may be obtained from the University Calendar and from the Registrar.

CAMBRIDGE.

At the University of Cambridge five years of medical study are required for the M.B. and B.C. degrees. The candidate must have resided nine terms (three years) in the university, and have passed the "previous" examination in classics and mathematics. There are three examinations: the first in chemistry, physics, and biology; the second in human anatomy, physiology, and (2) pharmaceutical chemistry; and the third, in the usual practical subjects with hygiene and pathology; each examination is divided into two parts, which can be taken separately. Subsequently to the third examination an Act has to be kept, which consists in reading an original thesis, followed by an oral examination on the subject of the thesis. As the subjects for the examination for the degree in surgery are included in the third examination for the M.B. degree, candidates are admitted to the degree of Bachelor of Surgery on passing the third examination for Bachelor of Medicine.

The M.D. degree may be taken three years after the M.B. An Act has to be kept, with oral examinations and an essay to be written extempore. There is also the degree of Master of Surgery, for which the candidate, having already passed for B.C., or being M.A., has otherwise qualified in surgery, has to pursue extra study in surgery, and has a special examination or submit original contributions of merit to the science or art of surgery. The yearly expenditure of a student who keeps his term by a residence in a college is from £150 to £200 a year. This, however, may include all payments to the University and the College—all fees as well as clothes, pocket money, travelling expenses, &c. Non-collegiate students have only to pay the University fees, which are not large. They lodge and board as they like; their expenses, therefore, are entirely in their own hands.

The University degree grants a diploma in public health without the necessity of residence, the examination being in so much of State medicine as is comprised in the functions of officers of health, and subject to the latest requirements of the General Medical Council. These examinations are held in Cambridge the first week in April and October. Candidates, whose names must be on the Medical Register of the United Kingdom, and need not be members of the University, should send in their applications to the Secretary of the State Medicine Syndicate a fortnight in advance. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a testimonial testifying to his competent knowledge of the subjects comprised in the duties of a medical officer of health.

An abstract of all Regulations may be obtained upon sending a stamped directed envelope to the Assistant Registrary, Cambridge. Full information is contained in the University Calendar.

UNIVERSITY OF LONDON.

The Matriculation Examination.—Candidates for any degree in this University *must* have passed the matriculation examination. It is held twice in each year—on the second Monday in January and the second Monday in June; not only at the University of London, but also, under special arrangement, in other parts of the United Kingdom and in the colonies.

The Preliminary Scientific M.B. Examination.—Professional studies pursued before the whole of this examination has been passed will not count towards the course required for the M.B. degree. The subjects are (*a*) chemistry and physics, (*b*) general biology. The examination takes place twice in each year, once for Pass and Honours, commencing on the third Monday in July, and once for Pass candidates only, commencing on the third Monday in January.

Intermediate Examination.—The Intermediate Examination in Medicine takes place twice in each year—once for Pass and Honours, commencing on the second Monday in July, and once for Pass candidates only, commencing on the third Monday in January. The subjects of the examination are anatomy, physiology and histology, organic chemistry, materia medica, and pharmaceutical chemistry. No candidate shall be admitted to this examination until nineteen years of age, and unless he has passed the Preliminary Scientific Examination at least two years previously. Fee for this examination, £5.

M.B. Examination.—This examination is held for Pass and Honours in October, and for Pass only in May. The candidate must have passed the Intermediate Examination at least twenty-one months earlier, must have attended lectures and hospital practice in a recognised medical school for two years, including at least two months' attendance on lunacy and infectious diseases, one of which must be subsequent to the Intermediate Examination, must have conducted at least twenty labours, and have acquired proficiency in vaccination.

Bachelor of Surgery.—The examination for the degree of Bachelor of Surgery takes place once in each year, in December. Candidates must produce certificates to the following effect:—1. Of having passed the examination for the degree of Bachelor of Medicine in this University. 2. Of having attended a course of instruction in operative surgery, and of having operated on the dead subject. The subjects of the examination are surgery (including operations on the dead body), pathology, and surgical anatomy. Fee, £5.

Master in Surgery.—The examination for the degree of Master in Surgery takes place once in each year, in December. Candidates must be bachelors of surgery of at least two years' standing; one year is, however, remitted in the case of candidates who passed the B.S. examination in the first division. The examination comprises mental physiology, surgery, and surgical anatomy.

Degree of Doctor of Medicine.—The degree of Doctor of Medicine is granted after examination to bachelors of medicine of at least two years' standing (reduced to one year if the candidate passed the preliminary examination in the first division). The examination comprises mental physiology and medicine, and is conducted by written papers, clinical examination, and *viva voce*. A candidate who presents a thesis approved by the examiners is excused the written examination.

Degree of Doctor in State Medicine.—This degree is granted to bachelors of medicine after examination on producing evidence (1) of having been engaged in the study of State Medicine for at least two years, (2) of having studied State Medicine for *one* year and of having held the post of Medical Officer of Health for two years, (3) of having held the post of Medical Officer of Health for *three* years. The examination is the same as for the ordinary M.D., with the exception that State Medicine takes the place of medicine.

Prizes.—1. The Sherbrooke Prize is awarded triennially for the best essay, embodying original research in some branch of science.

2. The Granville Prize is awarded in each of the two years intervening between the several awards of the Sherbrooke Prize.

Exhibitions or scholarships are awarded to the first six candidates in honours at the matriculation examination, and, if thought proper, to the first candidate in honours at the other examinations.

UNIVERSITY OF DURHAM.

One diploma and six degrees in Medicine and Hygiene are conferred, viz., the degrees of Bachelor in Medicine, Bachelor in Surgery, Master in Surgery, Doctor in Medicine, Bachelor in Hygiene, and Doctor in Hygiene, and Diploma in Public Health. These degrees are open to both men and women.

For the degree of Bachelor in Medicine (M.B.) there are four professional examinations. The subjects for the first are: Elementary anatomy and elementary biology, chemistry, and physics. For the second: Anatomy, physiology, materia medica, therapeutics, and pharmacology. For the third: Pathology, medical jurisprudence, public health, and elementary bacteriology; and for the fourth: Medicine, clinical medicine, and psychological medicine, surgery, and clinical surgery, midwifery, and diseases of women and children.

It is required that one of the five years of professional education shall be spent in attendance at the University College of Medicine, and the Royal Infirmary, Newcastle-upon-Tyne.

Candidates who have passed the First and Second Examinations of the University will be exempt from the First and Second Examination of the Conjoint Board.

For the degree of Bachelor in Surgery (B.S.) every candidate must have passed the examination for the degree of Bachelor of Medicine of the University of Durham, and must have attended one course of lectures on operative surgery, and one course on regional anatomy. Candidates will be required to perform operations on the dead body, and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of Master in Surgery (M.S.) candidates must not be less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examination in Arts for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor in Surgery of the University of Durham, and must have been engaged for at least two years, subsequently to the date of acquirement of the degree of bachelor in surgery, in attendance on the practice of a recognised hospital, or in the naval or military service, or in medical or surgical practice.

For the degree of Doctor in Medicine (M.D.) candidates must be of not less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary examination in Arts for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor in Medicine of the University of Durham, and must have been engaged for at least two years, subsequently to the date of acquirement of the degree of Bachelor of Medicine, in attendance on the practice of a recognised hospital or in the military or naval services, or in medical and surgical practice.

Each candidate must prepare an essay, which must be type written, based on original research or observation, on some medical subject selected by himself, and approved by the Professor of Medicine, and must pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum so far as they are related to the subjects of the essay.

For regulations for degrees in Hygiene and for the diploma in Public Health see Calendar 1901-2.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the Secretary of the College of Medicine, Newcastle-on-Tyne.

Residence can be had in a separate hostel for female students at moderate inclusive fees for board, &c., particulars of which and any other college information will be given on application to Prof. Howden, Secretary, University of Durham College of Medicine, Newcastle-on-Tyne.

VICTORIA UNIVERSITY.

Colleges of the University: Owens College, Manchester; University College, Liverpool; and Yorkshire College, Leeds. Candidates for degrees in medicine and surgery must attend, during at least two years, classes in one of the colleges of the University.

The degrees in the Faculty of Medicine are Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M). All candidates for degrees in medicine and surgery are required to pass the Preliminary Examination, or to have passed such other examination as may from time to time be recognised for this purpose by the University.

The subjects of the Preliminary Examination are—1, Latin; 2, Elementary Mathematics; 3, Elementary Mechanics; 4, English; 5, one of the following:—(*a*) French; (*b*) German; (*c*) Greek; (*d*) Italian; (*e*) Spanish; (*f*) any other modern language, permission to present which has been obtained from the Board of Studies. Notice of intention to present either Italian or Spanish must be given before March 1st in each year.

Before admission to the degrees of Bachelor of Medicine and Surgery candidates are required to send in the usual certificates of age and study as at the other Universities.

All candidates for these degrees must pass three examinations, namely—the First examination; the Second examination; and the Final examination.

First Examination.—The subjects of the examination are, 1, Chemistry; 2, Elementary Biology; 3, Physics.

Candidates must have attended, during at least one year, courses of both lectures and laboratory work in each of the above-named subjects.

Second.—1, Anatomy, 2, Physiology (including physiological chemistry and histology); materia medica and pharmacy.

Candidates must have passed the First Examination, and have attended courses of instruction in anatomy (systematic and practical) during two winter sessions and one summer session, in physiology for *two* winter sessions, in materia medica and pharmacy for *one* summer session. Candidates may present themselves separately in (*a*) anatomy and physiology, (*b*) materia medica and pharmacy.

Final.—The examination is divided into two parts, which may be passed separately or on the same occasion, but the first part cannot be taken before the end of the third year, and the second part cannot be taken less than two years after passing Second M.B. or before the fifth year of medical study in accordance with the University regulations. The subjects of examination are as follows: 1, Pharmacology and therapeutics; 2, General pathology and morbid anatomy; 3, Forensic medicine and toxicology and public health; 4, Obstetrics and diseases of women; 5, Surgery, systematic, clinical, and practical; 6, Medicine, systematic and clinical, including mental diseases and diseases of children. Candidates may select as a first part of the examination two or three of the subjects 1, 2, and 3.

The certificates required from candidates at the final examination are practically the same as for the corresponding examination at the London University, and only those who have previously passed the second examination are admitted to it. The regulations relating to the M.D. and Ch.M. degrees can be obtained on application to the Registrar.

Fees.—Preliminary examination, £2; for any subsequent examination, £1. First examination, £5; for any subsequent examination, £2. The fees for the second examination, for the final examination, and for the examination for the degree of Ch.M. are the same as for the first examination. A fee of £10 is payable on the conferring of the degree of M.D., a fee of £4 on the conferring of the degree of Ch.M.

The Preliminary examination is held in June and about the end of September. The first M.B. and Ch.B. is held in June; also about the end of September. The second and final examinations are held in March and July, the examination for Ch.M. in July only.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants degrees of M.B., Ch.B., M.D., Ch.M., and also a B.Sc. in the subject of public health. In order to obtain any of these degrees it is necessary that a student shall have passed at least the first four years of his curriculum in attendance upon the classes of the university.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed either the matriculation examination of the university or one of the following examinations, which will be accepted in lieu thereof for the present:—(*a*) The previous examination of the University of Cambridge. (*b*) Responsions of the University of Oxford. (*c*) The matriculation examination of any other university in the United Kingdom. (*d*) The leaving certificate (higher) of the Oxford and Cambridge Boards. (*e*) The Oxford or Cambridge junior local examinations (first or second class honours). (*f*) The Oxford or Cambridge senior local examination (honours). (*g*) The College of Preceptors examination for first-class certificate.

Matriculation examinations are held in June and September each year.

Degrees of Doctor of Medicine and Master of Surgery.—Candidates for either of these degrees will be required either—(*a*) To present a thesis embodying original observations in some subject embraced in the medical curriculum and approved by a Board of Medical Examiners; or (*b*) to pass a general examination (written and practical) in medicine or surgery, according to the degree desired. The University also grants degrees in public health, for which ample provision has been made.

Dental Department.—The University grants the Degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.).

The General and Queen's Hospitals.—The practices of these hospitals are amalgamated for the purpose of clinical instruction under the direction of the Birmingham Clinical Board, by whom all schedules will be signed and all examinations conducted. The hospitals have a total of upwards of 400 beds. 6,000 in-patients and 80,000 out-patients are treated annually, and many valuable posts are open to students at both.

Further information can be obtained from Professor Windle, Dean, Medical Faculty.

THE ENGLISH COLLEGES.

The medical corporations in England are the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The two Royal Colleges now co-operate to hold a series of examinations, on passing which the candidate receives the diploma of Licentiate of the Royal College of Physicians (L.R.C.P.), and Member of the Royal College of Surgeons (M.R.C.S.). The Society of Apothecaries grants a complete diploma in medicine, surgery, and midwifery.

Conjoint Examining Board in England (Royal College of Physicians of London and the Royal College of Surgeons of England).

Candidates for the above licences are required to complete five years of professional study at recognised medical schools and hospitals, after passing the preliminary examination, of which six months may be spent at an institution recognised by the Board for instruction in chemistry, or one year may be passed at an institution recognised by the Board for instruction in chemistry and biology, to comply with the following regulations and to pass the examinations hereinafter set forth.

Professional Examinations.—There are three examinations, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed. Every candidate intending to present himself for examination is required to give notice in writing to the Secretary of the Examining Board, Examination Hall, Victoria Embankment, W.C., fourteen clear days before the day on which the examination commences, transmitting at the same time the required certificates.

The subjects of the first professional examination are —Chemistry and physics, practical pharmacy, and elementary biology. A candidate may, if he so desire, take this examination in three parts at different times. A candidate will be admitted to examination in chemistry and physics and elementary biology before registration as a medical student by the General Medical Council, and he may take pharmacy at any time during the curriculum. Rejection entails a delay of not less than three months from the date of rejection, and the candidate will be re-examined in the subject or subjects in which he has been rejected. If referred in chemistry or biology, he must produce evidence of further instruction at a recognised institution. Practical pharmacy may be passed at any time during the curriculum. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in medicine on any of the subjects of this examination conducted at a university in the United Kingdom, India, or in a British colony, will be exempt from examination in those subjects in which he has passed.

The fees for admission to the first examination are as follows:—For the whole examination, £10 10s.; for re-examination after rejection in Part I., £3 3s.; and for re-examination in each of the other parts, £2 2s.

The subjects of the second examination are anatomy and physiology. Candidates will be required to pass in both subjects at one and the same time. Candidates will be admissible to the second examination at the expiration of two winter sessions and one summer session (or fifteen months during the ordinary sessions) from the date of registration as medical students, and after the lapse of not less than nine months from the date of passing Parts I. and III. of the first examination.

A candidate referred at the second examination will be required, before being admitted to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teachers, in a recognised place of study, his anatomical and physiological studies during a period of not less than three months subsequently to the date of his reference.

The fees for admission to the second examinations are: £10 10s. for the whole examination, and £6 6s. for re-examination after rejection.

The subjects of the third and final examinations are:—Part I. Medicine, including medical anatomy, pathology, practical pharmacy, therapeutics, forensic medicine, and public health. Candidates who have passed in practical pharmacy at the first examination will not be re-examined in that subject at the third examination. Part II. Surgery, including pathology, surgical anatomy, and the use of surgical appliances. Part III. Midwifery and gynæcology. Candidates may take this examination in three parts separately, or they may present themselves for the whole examination at one time.

Fees for admission to the third or final examination are as follows:—For the whole examination, £15 15s. Part I.—For re-examination in medicine, including medical anatomy, pathology, therapeutics, forensic medicine, and public health, £5 5s.; for re-examination in practical pharmacy (if taken at this examination), £2 2s. Part II.—For re-examination in surgery, including pathology, surgical anatomy, and the use of surgical appliances, £5 5s. Part III.—For re-examination in midwifery and gynæcology, £3 3s.

A candidate referred on the third or final examination will not be admitted to re-examination until after the lapse of a period of no less than three months from the date of rejection, and will be required, before being admitted to re-examination, to produce a certificate, in regard to medicine and surgery, of having attended the medical and surgical practice, or the medical or surgical practice, as the case may be, during the period of his reference; and in regard to midwifery and diseases peculiar to women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

REGULATIONS FOR COLONIAL, INDIAN, AND FOREIGN CANDIDATES, AND UNIVERSITY CANDIDATES.

Persons holding a Colonial, Indian, or a foreign qualification entitling them to practise medicine in the country of origin, and conferred after a course of study and examinations equivalent to those required by the Royal Colleges, are admissible to the second and third (final) examinations forthwith.

Members of an University in the United Kingdom are, under certain conditions, eligible for admission to the third (final) examination two years after passing at their University in the subjects included in the first and second examinations of the Board.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

Licentiates.—Candidates are now subject to the regulations of the Conjoint Examining Board in England.

The following by-laws, amended in conformity with the revised regulations of the Conjoint Examining Board, were re-enacted as follows:—

"Every candidate for the college licence (unless specially exempted) shall be required to produce satisfactory evidence of having passed before the commencement of professional study a preliminary examination on subjects of general education recognised by the college.

"Every candidate shall be required to produce satisfactory evidence of having completed five years of professional study, after passing a recognised preliminary examination before admission to the final examination.

"A candidate shall not be admitted to the second examination until the completion of two winter sessions and one summer session (or 15 months during the ordinary sessions) at a recognised medical school, nor until the expiration of one winter and one summer session after passing Parts I. and III. of the first examination.

"A candidate shall not be admitted to the third (or final) examination till the expiration of five winter and five summer sessions from the date of passing the preliminary examination and of four winter and four summer sessions after passing Parts I. and III. of the first examination, and of two winter and two summer sessions after passing the second examination."

Members.—The membership of the college is granted after examination to persons above the age of 25 years who do not engage in trade, do not dispense medicine, and do not practise in partnership. This diploma is only granted to persons already registered, or who have passed the final examination for the licence.

Medical graduates of a recognised university are admitted to a pass examination, but others must have passed the examinations required for the licence of the college. The examination, which is held in January, April, July, and October, is partly written and partly oral. It is directed to medicine, and is conducted by the president and censors. Candidates under 40, unless they have obtained a degree in arts in a British university, are examined in Latin, and either Greek, French, or German. Candidates over 40 are not so examined, and the examination in medicine may in their case be modified under conditions to be ascertained by application to the Registrar. The fee for the membership is £42, but if the candidate is a licentiate £15 5s. is deducted. In either case £6 6s. has to be paid before examination.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEMBERSHIP.—The candidates are now subject to the regulations of the Conjoint Board.

Fellowship.—The Fellowship of the College of Surgeons is granted after examination to persons at least 25 years of age, who have been engaged in professional studies for six years. There are two examinations—the first in anatomy and physiology, which may be passed after the third winter session; the second chiefly directed to surgery, which may be passed after six years of professional study. The second examination may be passed before attaining the age of 25, but the diploma is not granted until that age is reached. Candidates for this part of the examination must have passed the final examination of the Conjoint Board in England, and have been admitted members of the college before they can be admitted thereto, except in the case of graduates in medicine and surgery of recognised universities of not less than four years' standing.

Fees.—First examination, £5 5s.; second examination, £12 12s. The total fee payable on admission to the Fellowship is £31 10s., except for members, when the fee is £21. (The examination fees to the extent of £17 17s. count as part of the total fee.) Further information can be obtained on application to the Secretary of the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.

There are two examinations—primary and final. The primary examination is held quarterly on the first Wednesday, and on the Monday and Tuesday in the same week, in the months of January, April, July, and October. The final examination is held monthly.

Society of Apothecaries of London.

Primary Examination.—This examination consists of two parts: Part I.—Elementary Biology, Chemistry, Chemical Physics, including the Elementary Mechanics of Solids and Fluids; Heat, Light, and Electricity; Practical Chemistry, Materia Medica, and Pharmacy. A synopsis indicating the range of the subjects may be obtained on application. Part II.—Anatomy and Physiology and Histology. The examination is held in January, April, July, and October.

The final examination is held monthly, and is divided into Sections 1 and 2.

Section 1 consists of three parts.

Part I. includes: Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulations, Instruments and Appliances.

Part II. includes: (*a*) The Principles and Practice of Medicine, including Therapeutics, Pharmacology, Pathology, and Morbid Histology. (*b*) Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases.

Candidates passing either (*a*) or (*b*) will not be re-examined therein.

Part III. includes: Midwifery, Gynæcology, and Diseases of New-born Children, Obstetric Instruments and Appliances. Candidates may enter for Parts I., II., and III., together or separately.

Section 1 of the Final Examination, or any part thereof, cannot be passed before the expiration of 45 months from the date of registration as a medical student.

Section 2.—This section consists of two parts.

Part I.—Clinical Surgery.

Part II.—Clinical Medicine and Medical Anatomy. Section 2 cannot be passed before the expiration of the fifth year.

Fees.—Primary examination, £10 10s.; final examination, £10 10s.; total fee, £21.

Further information, with particulars as to the course of study, and of the certificates required, can be obtained from the Secretary to the Court of Examiners, Apothecaries' Hall, E.C.

This licence is a registrable diploma in Medicine, Surgery, and Midwifery, and qualifies the holder to compete for medical appointments in the Army, Navy, and Indian Services, also for Poor-law, Civil, and Colonial appointments.

The War Office has directed a board or military commission to assemble to consider proposals for the decentralisation of Netley Hospital.

Ireland.

THE IRISH MEDICAL SYSTEM.

The system of medical teaching in Ireland differs from that in England in important particulars. In London each clinical hospital has its attached medical school, which is fully equipped, and which educates the students of that hospital and very seldom those of any other. In Dublin, on the contrary, the hospitals and schools are entirely separate (except that Sir Patrick Dun's Hospital is officially connected with Trinity College), and a student of any hospital is free to enter for the whole or any part of his course at any school or hospital he pleases. As might be expected, religion, social rank, and locality of residence have their influence in causing certain classes of students to resort to schools and hospitals suitable to their condition. But scholastic or collegiate regulations impose no restrictions as to the place of study, and as the school and hospital fees are paid in detail in Dublin, and not in a lump sum, as in London, the pupil is free to do as he pleases.

BOARD AND RESIDENCE.

There is in Dublin no organisation for domestic accommodation of medical students, save for those who are passing through Trinity College, in whose case rooms and "commons" (*i.e.*, dinner) are provided at fixed rates. Those who can afford to pay £6 6s. or £7 7s. per month for their lodging and maintenance may find accommodation in the family of some medical man who receives boarders, in which case they become members of the family for the time being. The majority of Dublin students, however, take a lodging in some economical locality, or they "chum" with some other student for the purpose. It is usual to contract with the lodging-house keeper for board or partial board, but some students cater for themselves.

COST OF MEDICAL EDUCATION IN IRELAND.

The cost of obtaining a medical qualification depends to some extent on the qualification sought. In this connection the following tables may be of use to the prospective student:—

COST OF MEDICAL EDUCATION.

School.	Cost.
School of Physic, Dub. Univ. ...	£119 14s.
Royal College of Surgeons School	£124 19s.
Catholic University School ...	£124 19s.
Queen's Colleges...	£110 (?)

COST OF DIPLOMAS OR DEGREES.

Qualifying Body.	Cost.
Dublin University	£27 (to this must be added £83 4s., the cost of obtaining an Arts degree).
Royal University	£15.
Conjoined Royal Colleges ...	£42.
Apothecaries' Hall	£22 1s.

Thus, the absolute payment will amount to somewhere between £125 and £229 18s., according as the teaching of the Queen's Colleges and the degrees of the Royal University, or the teaching and degrees of Dublin University, are taken. For the Conjoint Colleges the entire cost is £166 19s., taking the minimum mode of payment. So that, assuming that extras or voluntary costs are incurred, the total will vary, say from £170 to £200. "Grinding" usually costs £5 5s. for each of the four examinations, but if a student needs private instruction in special subjects he must pay extra for it.

This sum, or something like it, may be expended by the student or his parent in paying for lectures, &c., and examination fees as they fall due, and there is no difficulty in obtaining the needful information for his guidance if he likes to pay for his course in this fashion. If, on the other hand. he prefers to pay a large sum down, he can "apprentice" himself to a teacher who will undertake all monetary responsibility for his education, and who may be able to give him some special advantage as his own pupil at hospital. This so-called "apprenticeship," is very generally a simple contract for the payment of fees, and involves but little special teaching. All the Dublin schools require fees to be paid in advance.

DATE OF ENTRY.

The entry of names and commencement of study in Ireland is *supposed* to date from the 1st of October in each year, but the session really dates from the 1st of November, and the entry of names may be delayed by the dilatory to the 25th of the same month. It should, however, be recollected that no credit is given for studies or attendance until the entry is regularly made. The student must attend three-fourths of the lectures delivered, and if he loses a fortnight at the beginning he must make up for it afterwards by constant attendance.

The student begins work by attending a recognised medical school each morning at ten o'clock, and occupying his day, to five p.m., between lectures and dissections. His vacations are a fortnight at Christmas and a week at Easter, and he finally returns home at the end of June.

PRELIMINARY EXAMINATIONS.

The first act of the student is to pass a preliminary examination, without which he cannot get credit for any medical studies pursued. The next is to commence medical study. This he does by entering for lectures at a medical school. From the school registrar he gets a form of certificate, and his third act is to take it or send it to the Branch Medical Council, 35, Dawson Street, Dublin. He is thereupon placed upon the Register of Medical Students (without fee) and his period of study counts from that date. He must register at the earliest possible moment, or he may lose credit for his work.

The only preliminary examination held specially for medical students is that held conjointly by the Royal Colleges of Physicians and Surgeons, but other examinations, *e g.*, the public entrance at Trinity College, the matriculation of the Royal University, the Intermediate Education passes in the required subjects, and all other examinations recognised by the General Medical Council are accepted as equivalent.

The subjects of examination as prescribed by the General Medical Council are as follows:—1. English language, including a specified author, dictation, grammar, and composition; also parsing and analysis from the book specified, 2. Latin, including grammar, translation from specified authors, and translation of easy passages not taken from such authors. 3. Elements of mathematics, comprising (a) arithmetic, including vulgar and decimal fractions: (b) algebra, including simple equations; (c) geometry, Euclid, Books I., II., and III., with easy deductions. 4. One of the following optional subjects:—(a) Greek, (b) French, (c) German. The books specified are:—1. English—Shakespeare, "Merchant of Venice." 2. Latin—The first and second books of the "Æneid," or the "Jugurthine Wars," or the third book of Livy. 3. Greek—The first book of the "Iliad," or the first book of Xenophon's "Anabasis." 4. French—Fénélon's "Télémaque," Books I., II, III. 5. German—Schiller's "Wilhelm Tell."

QUALIFICATION IN IRELAND.

THE Medical Licensing Bodies of Ireland are four in number, and, as a rule, students gravitate into one or other of five classes:—*a.* Those who enter Trinity College, and take a full graduation in Arts in addition to their professional degrees. *b.* Those who take the licence of the conjoined Royal Colleges of Physicians and Surgeons. *c.* Those who take the licence of the Apothecaries' Hall. *d.* Those who take their qualifications at the Royal University of Ireland, where graduation in Arts is not necessary. *e.* Those who pursue their studies in Ireland, but who migrate to London, Edinburgh, or Glasgow for their licences. Almost all these last-named emigrants come from the Queen's Colleges, and the greater number of them from Belfast, while the Dublin students qualify, as a rule, in Dublin.

We do not attempt to give details as to the requisite courses of instruction for degrees or diplomata, as our epitome must necessarily be insufficient for the information of the student, and we can occupy our available space with information more useful to him. The official information upon which students may depend can be obtained by sending a note to the Registrars of the Licensing Bodies or Schools.

The Irish Licensing Bodies are as follows:—

THE UNIVERSITY OF DUBLIN.

THE University of Dublin grants the degrees of M.B., B.Ch., and B.A O. to students who have obtained their Arts degree, and who have been for at least five Academic years on the books of the Medical School, and the higher degrees of M.D., M.Ch., and M.A.O. to those who have held, or have been qualified to hold, for at least three years, the grade of M B. and B.Ch. It does not grant degrees to any but full graduates in Arts, consequently its degrees hold the highest rank of social and educational qualifications, and are sought for by those who look forward to occupying the best positions in the profession.

The expense of obtaining the degrees of M.B., B.Ch., and B.A.O. is approximately as follows:—Lectures, £64 11s. 6d.; Hospitals, £55 13s.; Degree Fees, £27.—Total, £147 4s. 6d.

The expense of the B.A., amounting altogether to £83 4s., should be added, making the total cost £230 8s. 6d.

In addition to its ordinary qualifications the University grants the following higher degrees:—

Doctor of Medicine.—To obtain this the candidate must have obtained the degree of M.B., or have been qualified to have obtained it for three years. He must then read a thesis before the Regius Professor of Medicine. Total fee for this degree, £13.

Master in Surgery.—The candidate must be a Bachelor in Surgery of three years' standing, and must then pass an examination in clinical surgery, operative surgery, surgical pathology, surgery, and surgical anatomy (on the dead subject). Fee for degree, £11.

Master in Obstetric Science.—The candidate must have passed the M.B. and B.Ch. examinations, and have completed, in addition to the courses for M.B., B.Ch., a course in obstetric medicine and surgery. He is then required to pass an examination in the following subjects:—Practice of midwifery, gynæcology, anatomy of female pelvis and elementary embryology, and clinical gynæcology. Fee for this degree, £5.

Diplomate in Medicine, Surgery, and Midwifery.—Candidates for the diplomas in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine, and must have completed two years in Arts and five years in Medical studies. The course and examination is the same as for the degrees, except that the lectures and examinations in botany and zoology need not have been taken out or passed, and that the candidate need not have obtained an Arts degree. Fee for the diplomas in medicine, surgery, and midwifery, £21. A diplomate, on completing his course in Arts and proceeding to the degree of B.A., may become a Bachelor by attending the lectures on botany and zoology, passing the previous medical examination in those subjects, and paying the degree fees.

Qualification in State Medicine.—The candidate must be a M.D. of Dublin, Oxford, or Cambridge, must have completed, subsequent to registration, six months' practical instruction in a laboratory, and also have studied practically outdoor sanitary work for six months, under an approved Officer of Health (*v.* also page 304).

THE ROYAL UNIVERSITY OF IRELAND.

The Royal University of Ireland is purely an examining body. Its degrees are granted on one year's acts, *i.e.*, the matriculation examination of this University (none other will suffice) and a "first University examination" at the termination of the first year. The cost of the M.B. and M.Ch. of the University, with all the necessary curriculum, is about £125. Some of the Arts examinations are conducted, not only in Dublin, but at certain local centres.

The University confers the following medical degrees:—

M.B, B.Ch., B.A.O., and the higher degrees of M.D., M.Ch., and M.A.O. It also confers a diploma in sanitary science and a diploma in mental diseases.

All degrees are open to persons of either sex.

The university examinations are held in the spring, beginning about May 1st, and in the autumn, beginning about October 1st.

All candidates for any degree must pass the matriculation examination and the first university examination.

The course for the degree of M.B.. B.Ch., B.A.O., extends over five years.

Students will be admitted to the first university examination after one year from matriculation. Fee, £1.

The medical course consists of three previous examinations, one at the end of each year, and one degree examination at the end of the fifth year. Fee for each previous examination, £1; for the degree examination, £2: for the diploma, £10.

In addition the following degrees are granted:—

Diploma in Sanitary Science.—Conferred only on graduates in medicine of the university of at least twelve months' standing. Fee, £2. Subjects.—Climatology, chemistry, geology, physics, vital statistics, hygiene, sanitary law.

The M.D. Degree.—Conferred only on graduates in medicine of the university of three years' standing. They must at the same time produce a certificate of having been, for at least two academical years, engaged in hospital or private, medical, surgical, or obstetrical practice, or in the military or naval medical service. Fee, £5. The examination comprises medical diseases and the theory and practice of medicine, including pathology. Every candidate will be examined at the bedside, and required to diagnose at least three medical cases, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners and to discuss the questions arising therefrom.

The M.Ch. Degree.—Conferred only on graduates in medicine of the university of three years' standing, and who can produce a similar certificate of practice to that required for the M.D. degree. Fee, £5.

The examination comprises surgery, both theoretical and operative; surgical anatomy; ophthalmology and otology.

The Mastership of Obstetrics.—Conferred only on graduates in medicine of the university of three years' standing, and who can produce a similar certificate of practice to that required for the M.D. and M.Ch. degrees. Fee, £5.

The examination comprises midwifery and diseases of women and children.

Prizes, &c.—First Examination in Medicine. Two first-class exhibitions of £20 each, and two second of £10 each.

Second Examination in Medicine.—Two first-class of £25, and two second-class of £15, and the Dr. Henry Hutchinson, Stewart Medical Scholarship, value £10.

The Henry Hutchinson, Stewart Medical Scholarships, in psychological medicine, diseases of the nervous system, and anatomy physiology and pathology of brain, cord, and nerves. Competition among medical graduates of not more than two years' standing. Fee £2.

Third Examination in Medicine.—Two first-class exhibitions of £30 each, and two second of £20 each.

Medical Degrees Examination.—Two first-class exhibitions of £40 each, and two seconds of £25 each. One travelling medical scholarship of £100. One medical studentship of £200 per annum, tenable for two years.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

The examinations held conjointly by the two Colleges are the inlet of most Irish students to the profession, especially of those educated in Dublin. The course, as in other bodies, extends over five years, with examinations at the end of the first, second, third, and final years. These examinations are conducted by examiners chosen by each of the Colleges for the subjects appropriate to them. The curriculum has recently been revised, and made of a more practical nature. In common with the English Colleges, the subjects of the First Professional Examination may be studied either at a medical school, or at an institution other than a medical school recognised by the Colleges, after due inspection, for instruction in these subjects. We recommend students to apply for the official programme to the Secretary of the Committee of Management, Royal College of Physicians, or to the Registrar of either College. In the case of the Preliminary Examination seven clear days' notice must be given to the Secretary.

The total of the examination fees, spread over the four examinations, is £42, while the school and hospital fees, if taken in Dublin, amount to £124 19s., making altogether £166 19s., exclusive of re-examination fees, which have to be paid in case the candidate fails to pass his examination at the first attempt.

The conjoined Colleges also confer a diploma in Public Health, of which information will be found on page 304.

ROYAL COLLEGE OF PHYSICIANS IN IRELAND.

This College issues a licence in Medicine and a licence in Midwifery to registered medical practitioners.

The subjects of examination for the former qualification are:—Practice of medicine, clinical medicine, pathology, medical jurisprudence, midwifery, hygiene and therapeutics.

The candidate for the licence in Midwifery must produce certificates of having attended a course of lectures on midwifery, and of having attended practical midwifery and diseases of women for six months, at a lying-in hospital or maternity recognised by the College; or, where such hospital attendance cannot have been obtained during any period of the candidate's course of study, of having been engaged in practical midwifery under the supervision of a registered practitioner holding a public medical appointment, the certificate in either case to state that at least twenty labour cases have been actually attended. A registered medical practitioner of five years' standing is exempted from the examination by printed questions.

Fees.—Fee for the licence to practise medicine, £15 15s. Fee for examination for the licence to practise midwifery, £3 3s.

Membership.—A candidate for the membership of the College must be twenty-five years of age and a licentiate of the College of three years' standing; or, if a graduate of Arts of a university in the United Kingdom, or a practitioner of seven years' standing, a Licentiate of one year's standing. He must not be engaged in trade, dispense medicine, or practise in partnership. He must also have held during at least six months the office of resident physician or resident medical pupil, or have acted during the same period as medical clinical clerk in a recognised hospital, or have been in medical charge for at least twelve months of a public institution for the treatment of the sick. Every candidate must pass an examination in principles of medicine, practice of medicine, and clinical medicine. The fee for the examination is £21.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

This College grants a license in Medicine to registered medical practitioners. Candidates who hold registrable surgical diplomas, including the licence of the Apothecaries' Society of London, granted since October, 1886 are admitted to examination without further evidence of study, but candidates who hold medical qualifications only, including the L.S.A. granted before October, 1886, will be required to produce certificates of two courses of lectures in anatomy and dissections, one course of practical histology, one course of lectures in surgery, and one course of operative surgery.

Candidates are examined in surgery, clinical and operative; surgical appliances; and ophthalmic surgery. The fee is £26 5s. The fee for a special examination is £31 10s.

A diploma in midwifery is also granted after examination to registered medical practitioners. Candidates must produce evidence of (*a*) attendance on a course of lectures on midwifery and diseases of women and children in a recognised school; (*b*) attendance on six months' practice at a recognised lying-in hospital or recognised dispensary for lying-in women and children; and (*c*) of having conducted at least thirty labour cases. The fee for the examination is £15 15s.

Fellowship.—Candidates for the Fellowship of the College must enter their names with the Registrar at least a month before the date of examination, in order that the Council may decide whether to approve of the application. If the application is approved, the candidate will be admitted to the next sessional examination or to a special examination if granted by the Council. Candidates are divided into two grades:—

Grade 1.—Licentiates or graduates in surgery of less than ten years' standing.

Grade 2.—Licentiates or graduates in surgery of more than ten years' standing.

Candidates in Grade 1 must pass two examinations—Primary (in anatomy and physiology) and Final (in surgery). Candidates in Grade 2 need pass but one examination in surgery.

Fees.—Grade 1.—For Licentiates of College: Primary examination, £15 15s.; Final examination, £10 10s. Licentiates in Surgery of other licensing bodies: Primary examination, £26 5s.; Final examination, £15 15. Students of the College: Primary examination, £5 5s.; Final examination, £21. Students of other licensing bodies: Primary examination, £10 10s.; Final examination, £31 10s.

Grade 2.—Licentiates of the College, £26 5s.; Licentiates in Surgery of other licensing bodies, £42.

APOTHECARIES' HALL OF IRELAND (L.A.H.).

This body is authorised to grant a complete qualification in medicine, surgery, and midwifery, recognised and registrable under the Medical Act of 1886, and entitling the holder to occupy medical appointments in all the public services. It also confers the legal right to dispense medicines in Ireland. The examinations are held on the third Monday in January, April, July, and October, and the requirements in respect of studies are approximately the same as those of the Conjoint Examinations of the Royal Colleges of Physicians and Surgeons in Ireland. The examination fees payable for the qualification of L.A.H. are as follows:—First professional, £5 5s.; second, £5 5s.; third, £5 5s.; final examination, £6 6s.

The fees for re-examination are £1 1s. for each subject, excepting in the subjects of chemistry, pharmacy, surgery, medicine, second anatomy, and ophthalmology, the fees for which are £2 2s.

The fee for final alone is £15 15s., when the other examinations have been taken elsewhere. Candidates may be admitted to a special examination under special circumstances, at an extra fee of ten guineas.

Each candidate must produce evidence of having before entering on medical studies passed a preliminary examination in general education recognised by the General Medical Council, and of having been registered by that Council as a student in medicine. Certificates of medical study will not be recognised if the commencement of the course to which the certificate refers dates more than fifteen days prior to such registration, except in the subjects of physics or biology. This registration is not undertaken by the Hall, but the student must apply to the Registrar of the General Medical Council that he may be so entered. The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar at 40, Mary Street, Dublin.

Candidates already on the *Register* will receive the diploma of the Hall on passing an examination in medicine, surgery, midwifery, and pharmacy, and paying a fee of ten guineas. If medicine or surgery are required two guineas extra will be charged. The candidate will be exempt from each of the above subjects, which are covered by his previous qualification or qualifications.

In addition to the qualifying diplomas awarded by the above bodies there are diplomas in special subjects awarded as well. These are the licence in Dentistry and the diploma in Public Health.

THE LICENCE IN DENTISTRY.

There is probably no specialty in surgery which gives as great a number of its practitioners a living and the prospect of an income as dentistry. A young man who has got his diploma and knows something of his business and is willing to attend to it, seldom fails to get a substantial foothold in Ireland in a few years. The Irish diploma in Dentistry is granted by the Royal College of Surgeons.

Course of Study for the Licence in Dentistry.—Candidates are required to pass three examinations, viz.:—Preliminary (in General Education), Primary Dental, and Final Dental.

The Primary Dental examination is in (1) Physics, (2) Chemistry, including Metallurgy, (3) Anatomy, (4) Physiology and Histology, (5) Surgery—all these subjects with special reference to dentistry. The examination fee is £10 10s. The Final examination is in (1) Dental Surgery—theoretical, clinical, and operative; (2) Dental Mechanics—theoretical, clinical, and practical, including metallurgy. The fee for this examination is, for a Licentiate of the College, £10 10s.; for any other candidate, £26 5s. Each of these examinations must be preceded by complete courses of study in these subjects.

Exemptions.—Candidates educated in England or Scotland are admitted to the examination on the production of the certificates that would be necessary for both Primary and Final examinations in their own countries. Furthermore, the College may admit to examination, *sine curriculo*, candidates whose names are on the *Dental Register*, and who are unable to furnish the certificates required by the foregoing regulations, on presentation of a special schedule of application, accompanied by such certificates they may have of general or professional education, and by the required fee.

THE DIPLOMA IN PUBLIC HEALTH.

This diploma is granted by Dublin University, the Royal University, and the conjoined Royal Colleges. Every candidate must be a registered medical practitioner. The examination is in:—(1) Chemistry (including chemical physics). (2) Engineering and Architecture. (3) Sanitary Law and Vital Statistics. (4) Hygiene. (5) Bacteriology. (6) Meteorology. The General Medical Council recommend that all candidates shall have studied in a special bacteriological laboratory, also for six months as pupil of a working medical officer of health, described, for Ireland, as "the medical officer of health of a county or of one or more sanitary districts having a population of not less than 30,000; or a medical officer of health who is a teacher in Public Health of a recognised medical school."

In addition to taking the prescribed course a candidate for the D.P.H. of the University of Dublin must be a Doctor in Medicine or a graduate in Medicine, Surgery, and Midwifery of Dublin, Oxford, or Cambridge, and his name must have been on the *Medical Register* for at least twelve months before the examination. The Royal University only confers its diploma on its own graduates.

THE IRISH MEDICAL SCHOOLS.

The Irish Medical Schools are as follows:—

The School of Physic of Dublin University.—This school is formed by an amalgamation of the School of Trinity College and of the College of Physicians.

Some of the professors in the schools are *ex officio* medical officers of Sir Patrick Dun's Hospital. The school is open to all students, and the instruction provided is of a high quality.

Every student of the school must be matriculated by the senior lecturer, for which a fee of 5s. is payable, but he need not attend any of the Arts course unless he desires to obtain a university licence or degree, in medicine, surgery, and midwifery. No student is permitted to matriculate unless he has passed the entrance examinations of the University, of the Royal University, of the College of Surgeons, or some other examination recognised by the General Medical Council.

Two medical scholarships are given annually at the School of Physic, value £20 per annum, tenable for two years, the examinations for which are held each year in June; one scholarship is given in anatomy and institutes of medicine; the other in zoology, chemistry, botany, and experimental physics.

A prize of £100 is awarded by the Board to the successful candidate at a special examination in alternate years in medicine or in surgery, provided that the merit be deemed sufficient. The successful candidate is required to spend three months in the study of medicine or surgery as the case may be, in Berlin, Paris, or Vienna. Before he can obtain the first instalment of £50 he must satisfy the Senior Lecturer that he possesses sufficient knowledge of a Continental language to derive full benefit from the prize. The examination is held in June, and is open to students who have passed the Degree Examination in Medicine or in Surgery, as the case may be, within two years of the examination.

In order to obtain the second sum of £50 the prizeman must have furnished to the Regius Professor his formal report on the hospitals attended by him, within two years from the time of obtaining the prize.

Class prizes are given at the end of the session of between £5 and £10 in value.

The John Mallet Purser Medal, founded by Prof. Purser's past pupils, is awarded annually to the student who, at the ordinary June "half M.B." Examination, shall obtain highest marks in Physiology and Histology, provided that he passes the examination in full.

The Royal College of Surgeons in Ireland. Schools of Surgery.—By the amalgamation of the Carmichael College and the Ledwich School with the School of the Royal College of Surgeons the combined schools form one of the largest medical teaching bodies in Ireland. These schools are attached by Charter to the Royal College of Surgeons. They are carried on within the College building, and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the Professors, and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting room nearly trebled, and special histological, pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction.

The diplomas of the College are open to students of either sex. Separate rooms have been provided, and careful provision made for the instruction and comfort of women students.

Prizes.—The Barker Prize, £21; the Carmichael Scholarship, £15; the Mayne Scholarship, £15. The Gold and Silver Medals in Surgery, and the Stoney Memorial Gold Medal in Anatomy.

Class Prizes of £2 and £1, accompanied by medals if sufficient merit is shown, will also be given in each subject. Prospectus and student's guide can be obtained on written application to the Registrar, Royal College of Surgeons, Dublin.

The Catholic University School is situated in Cecilia Street, Dame Street. It prepares students for all medical examinations, particularly those of the Irish Colleges of Physicians and Surgeons, and the Royal University of Ireland. The school has recently been rebuilt and refitted, its working space having thereby been nearly doubled, and several new laboratories, including those for the study of bacteriology and public health, have been added. The institution has also been recently chartered, under the Educational Endowment (Ireland) Act, and it is now controlled by a Board of Governors. The total fees for school and hospital courses is £160, payable as the courses are taken out.

The following Exhibitions are awarded annually:—Two first year's, value £12 10s. each; two second year's, value £10 each; one third year's Royal Exhibition of £12 10s.; one final Conjoint Colleges' Exhibition of £12 10s.; two large gold medals, besides several other class medals.

A Guide for Medical Students, which gives all the information required by parents, and by students who desire to join the medical profession, may be obtained free on application to the Registrar.

THE QUEEN'S COLLEGES—BELFAST, CORK, AND GALWAY.

These three important academic institutions were the special schools of the Queen's University. They have ceased to have any direct relation to a central examining body, but educate students for all colleges and degrees, and are maintained, as hitherto, by a handsome Government grant. The same curriculum as that formerly adopted is continued, and the various exhibitions and scholarships are still available. Each college has the disposal of about £1,500 per annum in scholarships and prizes. The curriculum is generally well adapted for preparation for the Royal University examination. The colleges are well adapted for high-class technical education, having lecture rooms provided with every appliance necessary in the modern training of a medical student. The colleges are completely equipped with students' reading rooms and lending libraries and refreshment rooms, and with all adjuncts to collegiate life, such as literary societies and athletic organisations. The expense of living in the collegiate towns is quite moderate. The course of lectures in the winter session must be diligently attended, no student obtaining a certificate who has not put in three-fourths of a course. The scholarship examinations are held in October.

QUEEN'S COLLEGE, BELFAST.

The total cost of the medical curriculum of the Royal University of Ireland, including examination fees and perpetual fee for the Royal Hospital, but not including fees for the special hospitals, is about £95. If the Conjoint Examination of the Royal Colleges is taken the expense is almost the same.

Clinical instruction is given at the Royal Victoria Hospital. The Maternity Hospital, the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital, the Ulster Eye, Ear, and Throat Hospital, and the District Lunatic Asylum are also open to students.

Prizes.—(1) Ten medical scholarships each year, value £20 each; (2) two Dunville studentships (one each alternate year), value £145 each; (3) one Andrews studentship each alternate year, value £145; (4) numerous sessional prizes.

During the summer session special classes are formed in bacteriology and clinical pathology, and during the winter facilities are afforded to medical men to work at these subjects in the pathological laboratories. Last summer a course of lectures and demonstrations was given in the anatomical department on the Advanced Anatomy of the Nervous System, and next summer it is expected that a similar course on some department of applied anatomy will be arranged.

A pamphlet containing full information can be had on application to the Registrar, Queen's College, Belfast.

QUEEN'S COLLEGE, CORK.

The arrangements in the Faculty of Medicine are made chiefly with reference to the requirements of the Royal University of Ireland, but students proceeding for the examinations of the Conjoint Boards of England, Scotland, or Ireland, the Society of Apothecaries of London, or the Apothecaries Hall of Ireland can arrange the courses of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance in the College are also accepted by the University of Cambridge. The total fees for the College lectures and Hospital attendances required by the Royal University of Ireland is about £85.

Clinical instruction is given at the North and South Infirmaries. Students can also attend the Mercy Hospital, the Cork Union Hospital, the County and City of Cork Lying-in Hospital, the Maternity, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglinton Lunatic Asylum. The winter session commences on October 27th, and ends at the end of April. The courses of the summer session are delivered in the months of April, May, and June.

Scholarships and Prizes.—Eight medical scholarships, two in each of the first four years, of the value of £25 each, and in the fifth year the Blaney Scholarship of the value of £35, and a Senior Exhibition, value £30. Three Exhibitions, one in practical medicine, one in practical surgery, and one in practical midwifery, each of the value of £15. Book prizes at the sessional examinations.

Further information can be obtained in the College Regulations, or on application to the Registrar, Queen's College, Cork.

QUEEN'S COLLEGE, GALWAY.

Clinical teaching is carried on in the Galway Hospital, established as a Public General Hospital (in the place of the County Galway Infirmary) by Act of Parliament (1892). The Galway Fever Hospital is also open to students. The Medical lectures are recognised by the Royal University of Ireland and the various Licensing Bodies in the United Kingdom.

PRIZES.—There are eight Junior Scholarships in Medicine of the annual value of £25 each. Two are tenable by matriculated students of the first, second, third, and fourth years. The Council has power to award exhibitions for distinguished answering. Sessional prizes are offered in each subject. A Senior Scholarship in Anatomy, value £40, the holder of which is usually appointed Demonstrator, is offered annually for competition, tenable for one year by a student who shall have attended the Medical School of the College for at least two sessions, and shall have obtained a Degree in Arts or Medicine, or a Diploma in Medicine from a Licensing Body. Scholarship examinations are held at the commencement, and those for Sessional Prizes at the close, of each session.

DEPARTMENT OF AGRICULTURE AND TECHNICAL INSTRUCTION FOR IRELAND.

ROYAL COLLEGE OF SCIENCE FOR IRELAND.

SESSION 1902-1903.

This College, situate in St. Stephen's Green, Dublin, supplies a complete course of instruction in science applicable to the industrial arts, especially those which may be cast broadly under the heads of chemical manufactures, engineering, physics and natural science. A diploma of Associate of the College is granted at the end of the three years' course. Non-Associate students may join for any course required. There are four Royal scholarships of the value of £50 each yearly, with free education, tenable for two years. Two are competed for by the associate students at the end of each session. The chemical, physical, zoological and botanical, geological and mineralogical laboratories and drawing schools are open daily for practical instruction. The Session commences on Wednesday, October 1st.

The courses of chemistry, physics, botany, geology and mineralogy, and zoology are recognised by the Royal University of Ireland, and certificates of attendance are granted to medical and other students attending these courses, as also the courses of the chemical, physical, zoological, botanical, and geological laboratories.

THE DUBLIN HOSPITALS.

The clinical hospitals in Dublin are ten in number, exclusive of three lying-in hospitals. There are also two children's hospitals, an orthopædic hospital, a fever hospital, an ophthalmic hospital with two centres, a dental hospital, and other special institutions. Some of the clinical hospitals, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies; while others, again, are without any special connection with any school. While, however, such affiliation of a school or hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is competent to attend any hospital or any school he wishes, and to change his place of instruction from year to year as he may see fit.

The Irish Licensing Bodies require attendance on hospitals for twenty-seven months, *i.e.*, three winter sessions of six months and three summers of three months, within the five years of study. The fee at all general hospitals is £8 8s. in winter, and for the summer £6 6s., or £12 12s. for the entire session of nine months if taken together.

GENERAL HOSPITALS.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.—The accommodation at these hospitals is as follows:—Hardwicke Hospital, 120 beds; Whitworth Hospital, 82 beds; Richmond Hospital, 110 beds—total, 312 beds. These hospitals are visited each morning at nine o'clock by the Physicians and Surgeons, and, in addition to the usual bedside instruction, clinical lectures are delivered on the most important cases. Special instruction is also given on various branches of medicine and surgery. The Truss Establishment, for the distribution of trusses to the ruptured poor of Ireland, is connected with these hospitals. There are very large ophthalmic, aural, throat, and gynæcological dispensaries, and instruction in these important subjects is given. Eight resident clinical clerks are appointed each half-year, and provided with furnished apartments, fuel, &c. The appointments are open not only to advanced students, as formerly, but also to those who are qualified in medicine or surgery. A house surgeon for the Richmond Hospital and a house physician for the Whitworth and Hardwicke Hospitals are elected annually, and receive a salary. The Richmond Lunatic Asylum, containing 1,600 beds, adjoin these hospitals.

MEATH HOSPITAL AND CO. DUBLIN INFIRMARY.—This hospital was founded in 1753, and now contains 160 beds available for clinical teaching. A new building for the isolated treatment of fevers, containing 40 beds, has recently been added. The certificates of this hospital are recognised by all the universities and licensing bodies of the United Kingdom. Medical and surgical resident pupils and clinical clerks and dressers are appointed every six months, and a house surgeon is elected annually. A prospectus giving the complete arrangements for medical and surgical classes for the coming session may be obtained from the secretary of the Medical Board, Mr. Lane Joynt, F.R.C.S.I., 84, Harcourt Street, Dublin.

* THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS are in Peter Street, and occupy a central position within a few minutes' walk of the College of Surgeons and Trinity College. From October 1st, the physicians and surgeons visit the wards and give instruction at the bedside at the advertised hours. There is a large detached fever hospital, and also wards for infants and children. Operations are performed, except in cases of urgency, at 10 a.m. on Tuesday, Thursday, and Saturday. Special hours are devoted to clinical instruction in the diseases peculiar to women, and students are individually instructed in the use of the stethoscope, ophthalmoscope, laryngoscope and microscope; also special instruction is given on practical pathology and X-ray photography. Three resident pupils are selected half-yearly and a house surgeon annually. Prize examinations, including examinations for the Hudson Scholarship, £30 and a gold medal, and a senior prize of £10 and a silver medal, in addition to surgical and medical prizes, are held at the termination of the session. The

large dispensaries afford facilities for the study of eye, ear, throat and cutaneous diseases, as well as of minor surgery and dentistry. Further particulars from Mr. Heuston, F.R.C.S.I., 15, Stephen's Green North.

Sir Patrick Dun's Hospital is situated on the south-eastern side of the city, and about half a mile from the University School of Physic. It is officered exclusively by the professors and examiners in that school. Formerly all University students were compelled to attend this hospital, which was purely a medical institution, but some years ago the obligation was removed, and the hospital was opened for surgical cases. It is now free to all students. There is a special wing devoted to fever cases, and regular clinical instruction is given by the members of the medical staff throughout the winter and summer sessions. Special classes for students commencing their hospital studies will be held in these departments during the months of October, November, and December. They will embrace the elements of medicine and surgery, including note-taking. Opportunities are also afforded to students for examining cases of throat, ear, and eye diseases, as well as for performing minor surgical operations and bandaging. In the X-ray Department opportunities are given the members of the hospital class of seeing the various applications of the X-rays to the diagnosis and treatment of injury and disease.

* **The Royal City of Dublin Hospital.**—This hospital is situated in Upper Baggot Street, about ten minutes' walk from the Royal College of Surgeons and Trinity College. It has just been enlarged and improved to a very considerable extent. A special course of instruction is given on ophthalmic and aural disease. There are special wards for the treatment of diseases of the eye, of children, and of women, and practical instruction is given on diseases peculiar to women; there is also a separate building for infectious diseases. Clinical clerks to the physicians and dressers to the surgeons are appointed from the most deserving of the class. A new operation theatre, sterilising room, and anæsthetic room have been constructed in accordance with the most modern surgical requirements. A resident medical officer is elected annually, and resident medical and surgical pupils are appointed from among the past and present students of the hospital. Operations are performed on Tuesdays, Thursdays, and Saturdays, at 10 a.m. Full particulars can be had on application to Mr. G. Jameson Johnston, M.B., F.R.C.S.I., Hon. Sec. Med. Board.

* **Mater Misericordiæ Hospital.**—This hospital, containing 335 beds, is open at all hours for the reception of accidents and urgent cases. Fifty beds are specially reserved for the reception of patients suffering from fever and other contagious diseases. A course of lectures and instruction on fever will be given during the winter and summer sessions. A certificate of attendance upon this course to meet the requirements of the various licensing bodies may be obtained. Opportunities are afforded for the study of the diseases of women in the wards under the care of the obstetric physician, and at the dispensary, held on Tuesdays and Saturdays. Lectures on clinical gynæcology will be delivered on Saturdays at 11 a.m. Ophthalmic surgery will be taught in the special wards and dispensary. A special course of instruction in pathology and bacteriology, as applied to medicine, will be given. Connected with the hospital are extensive dispensaries, which afford valuable opportunities for the study of general, medical and surgical diseases, accidents, &c. Leonard Prizes: One gold and one silver medal will be offered for competition annually in the subject of medicine, and one gold and one silver medal in the subject of surgery. Junior Leonard Prizes: Two prizes of the value of £3 and two prizes of the value of £2 will be offered for competition in medicine and surgery respectively.

* **Mercer's Hospital.**—This hospital, founded in 1707, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and within fifteen minutes' walk of Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork Street Fever Hospital, whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the posts of resident pupil, &c. There is a large out-patient department, and a special department for diseases peculiar to women. There are also special wards for the treatment and study of children's diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements. A house-surgeon is appointed annually. Five resident pupils are appointed, each for six months, and clinical clerks and dressers are appointed monthly from among the most deserving members of the class. The certificates of this hospital are recognised by all the licensing bodies. For further particulars apply to Mr. R. Charles B. Maunsell, M.B., F.R.C.S., 32, Lower Baggot Street, Dublin.

* **St. Vincent's Hospital**, Stephen's Green, Dublin, was established in 1834. The hospital has 160 beds, and in connection with it there is a largely-attended dispensary, a convalescent home, and a nurse's institute. In addition to the ordinary clinical instruction, systematic courses of lectures are given in each department of medicine and surgery, and are illustrated by cases in the hospitals. The resident officers consist of a house surgeon, a house physician, and four resident pupils. Three clinical lectures are delivered daily in the wards, illustrated by selected cases, and beginning at 9 a.m. Two gold medals and other valuable prizes and certificates of merit are awarded at the end of each session. A prospectus can be had from Dr. Tobin, St. Stephen's Green.

* **Dr. Steevens' Hospital**, situated at Kingsbridge, is one of the oldest and largest of the clinical hospitals in Dublin, and contains over 200 beds. Recently, a very fine Nurses' Home has been added to the institution, with accommodation for over seventy nurses. And a new and thoroughly equipped dispensary and out-patient department has been completed, and opened to patients. Licensing bodies recognise six months' residence as equivalent to a year's ordinary attendance at hospital. The manufactories and railway works in the neighbourhood supply this hospital with large numbers of accidents and other cases, while the special ward for venereal diseases affords exceptional opportunities for the study of this important subject.

* **Jervis Street Hospital, Dublin.**—Jervis Street Hospital is the oldest established in Dublin. The new hospital was completed in 1896, since which time it has been opened for the reception of patients. In addition to large medical and surgical dispensaries, the out-patient department includes special departments for the treatment of diseases of the skin, eye, ear, and throat, and diseases peculiar to women. Two resident surgeons are appointed annually. Clinical clerks and surgeons' dressers are selected from among the most attentive of the advanced students without the payment of any additional fee. Twelve interns are appointed annually, and are provided with apartments, &c., free of expense. Special certificates are given to resident pupils and dressers who have performed their respective duties to the satisfaction of the physicians and surgeons. Gold and silver medals are given after examinations held at the close of the summer session.

SPECIAL HOSPITALS.

The special hospitals of Dublin are the Rotunda, the Coombe, and the National Lying-in Hospitals, Cork Street Fever Hospital, the Royal Victoria Eye and Ear Hospital (amalgamation of St. Mark's Ophthalmic Hospital, and the National Eye and Ear Hospital), the Dental Hospital, the Throat Hospital, the Orthopædic Hospital, and the Children's Hospitals in Harcourt Street and in Temple Street.

The Rotunda Hospital.—This, the largest and best-known lying-in hospital of the United Kingdom, is every year becoming more appreciated as a school of midwifery, and as affording peculiar advantages both to the student and the practitioner for acquiring a thorough knowledge of gynæcology. It contains two distinct departments—viz., the lying-in hospital, into which about 1,800 cases of labour are admitted annually, and the hospital for the treatment of diseases peculiar to women, into which some 500 patients are now admitted during the course of the year. The present master, Dr. Purefoy, was previously well known as Gynæcologist to the Adelaide Hospital. There is a large extern maternity in connection with the hospital, more than 2,000 women being attended during the past year at their own homes, and also a large daily dispensary for the treatment of the diseases peculiar to women. Every facility is afforded for the study of the special departments of medicine to which the hospital is devoted, and both students and midwives are granted a diploma on passing an examination. Two clinical clerks, at a salary of £50 per annum each, are appointed every six months from among the students who have attended the full course of instruction in the hospital. A considerable number of female pupils are also yearly trained as nurse tenders and midwives.

Coombe Lying-in Hospital.—This hospital, which was rebuilt and considerably enlarged, and contains 65 beds, was founded in 1826 by Mrs. Boyle, and was incorporated by Royal Charter in 1867. This hospital is situated in the centre of a district densely populated by the lower orders, and thus affords the amplest opportunities for practice. It receives about 800 labour cases within its walls, while those attended as extern amount to more than 2,000 in number. Moreover, the chronic hospital for the reception of cases of the diseases of females gives admission to about 200 to 300 patients annually. The fee for attendance is £8 8s. for six months as extern, and £18 18s. as intern pupil. During that period, the pupil attends on given days and nights in each week, and takes charge in his turn of any case that may be admitted to the labour wards, or may call for his assistance outside. Two resident pupil midwifery assistantships and a clinical clerkship are obtainable half-yearly by all pupils who have obtained their midwifery diploma from the hospital, and special certificates are given. Lectures are delivered in the hospital, and clinical instruction is given daily at the bedside. Nurses who take out the usual hospital course of six months receive special instruction in midwifery, and can obtain their diplomas on the termination of the course.

* National Maternity Hospital.—This institution, under the mastership of Dr. Barry and Dr. A. Horne, is situated in Holles Street.

Sir Patrick Dun's Maternity.—This is a branch of Sir P. Dun's Hospital, and is under the management of the King's Professor of Midwifery in Dublin University. Students desirous of entering for twelve months' instruction in practical midwifery are required to pay a maternity fee of £3 3s. each to the Registrar of the hospital, and to send in their names to the Board of Governors before January 1st in each year. Students of Trinity College are not liable to any other payment for instruction in practical midwifery. Other students are required to pay £3 3s. each to the King's Professor, for twelve months' practical instruction, in addition to the hospital maternity fee. The certificates of Sir Patrick Dun's Hospital are recognised by the Royal University and the Conjoint Royal Colleges of England, Ireland, and Scotland.

Cork Street Fever Hospital is the only special fever hospital in Dublin. It is supported mainly by an annual government grant, and capitation grants for patients. Regular clinical instruction is given during the winter and summer session to those who desire a special course in fevers. All particulars may be obtained on application to the Registrar and Resident Medical Officer.

* The National Children's Hospital for the treatment of all non-infectious diseases peculiar to children, with which the Pitt Street Children's Hospital, founded in 1821, was amalgamated, is capable of containing 50 beds for the reception of cases of deformity and all other forms of surgical disease. There is a large general dispensary for extern patients held daily from 10 to 11. Operations are performed on Saturday at 12 o'clock. Practitioners and students can attend on application to Mr. Ormsby, F.R.C.S.I.

* Dublin Orthopædic Hospital, Great Brunswick Street, containing 40 beds for the treatment of every class of deformities and for the practice of orthopædic surgery. This institution is under the management of Mr. Swan, F.R.C.S.I.

The Royal Victoria Eye and Ear Hospital consists—until the new combined hospital is erected—of the two institutions which have, heretofore, given special instruction in ophthalmology, separately. They are:—(1) St. Mark's Ophthalmic Hospital and Dispensary in Lincoln Place.—This hospital was founded by the late Sir William Wilde, and contains 50 beds. Clinical lectures are delivered each morning, and operations are performed daily as occasion requires. Instruction in aural surgery is also given. (2) National Eye and Ear Infirmary, Molesworth Street.—This hospital contains 30 beds. Clinical instruction in diseases of the eye, including the use of the ophthalmoscope, is given daily. Operations at 12 o'clock. Instruction in aural surgery is also given. Afternoon classes for practical instruction in the use of the ophthalmoscope, &c., and for the demonstration of cases, are formed from time to time by the assistant surgeons.

* The Incorporated Dental Hospital, Lincoln Place.—This handsome hospital, recently erected, is the only special Dental Hospital in Dublin. It is officered by a very strong staff of the leading dental surgeons of Dublin, and has a large *clientèle* and extensive practice among the Dublin poor. The fees are £15 15s. for first year's study, and £12 12s. for second, and proportionately smaller fees for shorter periods.

The City Hospital for Diseases of the Skin.—Senior students are admitted free to the practice of this hospital, which has a large out-patient attendance (nearly 7,000 for year ending August, 1902). Classes of instruction in the use of the Finsen light and X-ray treatment as applied to dermatology, with demonstrations on cases already undergoing the treatment will be held at regular intervals during the winter and summer sessions.

* No returns have been received from these institutions, and consequently we cannot guarantee the accuracy of our information.

BELFAST HOSPITALS.

Hospital for Sick Children, Queen Street.—This institution, erected by voluntary donations, and supported by voluntary contributions, was opened for the reception of patients on April 24th, 1879. The hospital consists of a medical ward with twenty-eight beds, and one of a similar size for surgical cases. It is strictly non-sectarian in its principles, and is open to all denominations. Children from birth to the age of 12 years, and not suffering from contagious disease, are admissible as in-patients. A very large extern is conducted in the out-patient department between the hours of 9 and 10 a.m. where children from birth to 14 years are attended to The convalescent home, which is situated at Newtownbreda, contains thirteen cots, and its situation and equipment render it an admirable adjunct to the after-treatment of the cases admitted to the hospital. During the winter session systematic courses of lectures and demonstrations in the medical and surgical diseases of infancy and childhood are delivered in the wards on Wednesday and Friday of each week at 9 a.m.

* Mater Infirmorum Hospital.—Established 1883. 160 beds.

* Maternity Hospital.—Established 1794. 16 beds.

* Ophthalmic Institution, Eye and Ear Hospital, Gt. Victoria Street.—Established 1844; new hospital erected 1867. 30 beds.

* Royal Victoria Hospital.—Established 1814; incorporated by Royal Charter, 1875 and 1898. 209 beds; Convalescent Hospital, 30 beds; Children's Hospital, 40 beds; Consumptive Department, 10 beds.

* Ulster Eye, Ear, and Throat Hospital—Established 1871. New Hospital opened 1874. 30 beds.

Ulster Hospital for Children and Women, Mountpottinger, Belfast, is the only hospital in the large part of the city situated on the County Down side of the river. It is placed in a working-class district, and has a great field for its charitable operations. There are in the hospital about twenty-two beds for children and eight for women. There is an extern department for children open every week day, except Saturday, from 9 till 10, and for women at 11.30, and a special department for diseases of the eye, ear, and throat on Tuesdays and Fridays from 9 till 10. During the summer and winter sessions, clinical instruction is given to students daily, operations being chiefly performed on Wednesday and Friday. There is a resident midwife for extern work, and every facility is afforded students for attending their cases in the district.

CORK HOSPITALS.

*County and City of Cork Hospital for Women and Children.—Established 1874. 90 beds.

*County and City of Cork Lying-in Hospital.—Established 1798. 17 beds.

*Eye, Ear, and Throat Hospital, Western Road.—Incorporated 1898. 35 beds.

*Fever Hospital and House of Recovery.—Established 1801. 110 beds.

*Maternity.—Established 1872.

*Mercy Hospital.—Established 1857. 80 beds.

*North Charitable Infirmary.—Established 1774. 110 beds.

*South Charitable Infirmary and County Hospital.—Established 1773. 104 beds.

GALWAY HOSPITALS.

*County Hospital.—Established 1786. 60 beds.

*No answer to our request for information received from these hospitals.

IRISH PUBLIC SERVICES.

The Poor-law Medical Service.

Since the early part of 1899, a vital change has taken place in the Irish Poor-law Medical Service - the service which has, heretofore, absorbed most of the Irish rising medical generation. By the Irish Local Government Act the administration of the system, the appointment and payment and allocation of duties of medical officers, was transferred from the old Boards of Guardians, composed in due proportion of members elected by the local voters and members who acted *ex-officio* in virtue of property qualifications, to new boards composed wholly of the elected representatives. This change has had the most disastrous effect upon the service. The *ex-officio* guardians, *i.e.*, the local gentry, were, thereby, eliminated, and the sole control of the service has been transferred to the elected Guardians, who have, we regret to say, sought to place considerations of economy before everything—before the welfare of the poor, and before the just rights of the medical officer. Questions of religion and politics are so rampant on Irish elected Boards that the medical officer who is at variance on these matters with the majority of the Board, who governs him, has not a pleasant life. The Irish Medical Association, whose work it is to safeguard the interests and improve the condition of the Poor-law medical officer, considers it an imperative duty to point out to young practitioners the following facts:—(1) That the Poor-law Medical Service is one in which there is no promotion. (2) That it is a service where few facilities exist for original research, and still less for further medical culture, especially in the rural districts. (3) That, while medical education has become wider in its requirements, and more costly and difficult to procure, the same or a less rate of payment given to less educated men forty years ago is still offered, and this, too, at a time when the rural prosperity of the country is less, and consequently lucrative private practice more difficult to obtain.

We need go no further than to say that the Irish Poor-law Medical Service is a service to avoid. To all who contemplate entering it we emphatically say, Don't. So important is it that young medical men should recognise what life in the Poor-law Medical Service means at present, that we quote a short extract from a letter written by a member of it:—"We have no pay practically; no holidays. We are always on duty. We have no pension. We have no promotion. Consequently, every day spent in such a service is one day worse, which, I think, makes it fairly rank as the very worst service of any kind in the world, for any other service leads a man to promotion or pension. In addition, the fact of a man being in this service, as you know, lowers his social status. Everything points to it being a service to be shunned."

Reforms must come finally, but they will only come, as they have come in other services, in consequence of the dearth of candidates.

There are 159 workhouses and about 813 dispensary medical officers, besides apothecaries. The number of vacancies that occur annually averages 100. The salary in this service used to average about £114, but is rapidly coming down, and when it is taken into consideration that in the vast majority of rural districts it is necessary to keep one or more horses, the average area being from forty to sixty square miles, it is plain that there will not be a large margin left from the public emoluments.

The medical officer is also *ipso facto* the registrar of births, marriages, and deaths, and medical officer of health for the district, under the Public Health Act passed in 1873 and amended in 1878. The former office, in country districts, yields between £5 and £10 a year, and the emoluments of the latter appointment in very few cases reach £20, averaging about £12. The medical officer is also vaccinator for the locality, and is required to vaccinate everyone who wishes to come. For each patient a fee of 2s. is paid, along with his salary, by the guardians, and the sum total of those fees varies, according to the populousness of the district, from £4 to £100, an average for the provinces being about £10.

Qualifications.—The qualifications required by the Local Government Board are a licence in surgery, in medicine, and in midwifery; but registration in the *Medical Register*, if effected since the passing of the Medical Act, in 1886, fulfils all requirements. The candidate must also be 23 years of age.

The appointment to both workhouse and dispensary lies with the guardians, who elect by vote. As politics and religious feeling run high in Ireland, these elements enter largely into the election of Poor-law medical officers. Family interests also possesses great weight. In some districts an attempt has been made to insist upon the candidate being a member of the United Irish League. We need not—we trust—point out to any member of the medical profession that to endeavour to obtain a post on such a qualification is to commit an act which is unworthy of his profession.

Duties.—The duty of the dispensary doctor is two-fold. He is to attend his dispensary on a given day or days in the week. Frequently there are two dispensaries in the district, separated from each other by several miles, and he will have perhaps to attend two days a week. He has also to visit at any hour of the day or night a sick person for whose relief a visiting ticket has been issued by a member of the committee or the relieving officer, and to continue his attendance as often as may be necessary to the termination of the case. Moreover, he has a great many registry books to keep and a multitude of returns to make, and in many districts he has to make up all the medicines for the poor.

The pressure of these duties is in a great degree dependent on the goodwill of the guardians. If the medical man be a favourite with his masters they will give him very little trouble with "scarlet runners," as the visiting tickets are, from the colour in which they are printed, humorously called, and will be unwilling to trouble him even with cases deserving of personal attendance. If, on the other hand, it is his misfortune to differ from the guardian in religion or politics, his position may become impossible. He may be peremptorily summoned in any weather, at any hour, and to any distance, to a case which he may probably find to be altogether trivial, or to a person whom he may know to be perfectly well able to pay.

Workhouse Hospitals.—The number of unions in Ireland is 159, to each of which is attached a medical officer, who is appointed and controlled by the board of guardians in the same manner as the dispensary surgeon. The salary is usually better than that of the dispensary doctor, and the duties of a more easy and satisfactory description, inasmuch as they are confined to daily attendance at the workhouse hospitals, and no night visits out of doors or long journeys across the country are involved.

The Irish Lunacy Service.

This service, at present, affords a comfortable livelihood for 22 Resident Medical Superintendents and 32 Assistants. The Superintendents receive salaries and allowances ranging, according to the number of inmates of the asylum, from £500 to £1,000 a year, and the Assistants receive salaries and emoluments averaging about £200 a year. There are also Visiting Physicians receiving about £120 a year, but this class of officer is being allowed to die out, and no new appointments will be made. The Superintendents and Assistants must devote their whole time to their duties.

Heretofore the appointments of Medical Superintendents have been in the patronage of the Lord Lieutenant, but, under the new Local Government Act, they are in the hands of the County Councils, with the proviso that no one shall be appointed who is not a fully registered practitioner with five years' service as Assistant. The Assistant has been, heretofore, appointed by the Board of Governors, and will, in future be appointed by the Committee of the County Council to which the management of the asylum is entrusted. In addition to these officers, there are, in certain larger asylums, Clinical Residents, who receive about £50 a year and full allowances. Those appointments afford excellent introduction to the higher places in the service.

Other Appointments.

There are, in addition to those which we have mentioned, certain emoluments open to medical practitioners in special localities. They are:—

(1) Attendance on the Royal Irish Constabulary. (2) Attendance on the Coast Guards. (3) Factory Surgeoncies. (4) Attendance upon the depot soldiers who are not otherwise provided for.

The Constabulary are paid for at the rate of 2s. per month for each member of the force on duty in the district, including the wives and children of the men but not of the officers. This includes the supply of medicines. The appointment to this position rests with the Inspector-General of the Royal Irish Constabulary, who usually acts upon the advice of the local District Inspectors as to the convenience of the men, and, of course, the emoluments depend on the number of Constabulary stations and the number of men in each.

The Coastguard Service.—The duty of the Medical Officer is to attend the men when sick and to examine candidates either for admission or for superannuation. The fees vary from 5s. to 2s. 6d. per visit. The appointment rests with the Admiralty, but are usually secure for the local Poor law Medical Officer. In this case, also, emoluments depend on the number of stations and men.

Factory Surgeoncies are in the gift of the Chief Inspector of Factories in Whitehall. There is a set scale of payment by the factory owner to the inspector for this work, but we believe it is not adhered to, and, in some districts, at all events, the emolument is a matter of arrangement. The amount depends upon the size of the factory, the position being, in Dublin or Belfast or in other large manufacturing centres, a lucrative one, but in other places scarcely worth taking. The attendance on the military depots is not worth mentioning.

The names of the Professors, Lecturers, and Hospital Staffs of the foregoing Schools and Hospitals, are not included in this place, being found in the advertisement of each Institution, as indicated below.

Scotland.

Scotland still maintains her educational system at the high level to which it long ago attained, and, with a considerably less numerous population inhabiting her whole area than that of London alone, supports four venerable and historic Universities, each with an honoured past and a magnificent record. The Universities of Edinburgh, Glasgow, Aberdeen, and St. Andrews have sent forth many illustrious graduates in all the different branches of higher learning; few schools can show more gratifying results, and, now that the Carnegie Bequest is in full working order, a University education is within the reach of every Scotch lad, save the very poorest. In Edinburgh and Glasgow those who do not aspire to the honour of a University degree can obtain college diplomas and excellent medical teaching from extra-mural schools of almost equal renown.

The inhabitants of Scotland have always evinced a deeply-rooted dislike for constraint; the regulations of their Universities exemplify this. The student in Scotland is his own master; he lives where he likes, dines where he pleases, and can clothe himself in any kind of garment he chooses. In but one of the Universities have students to don gowns. No doubt the great freedom granted to students occasionally leads to unsatisfactory results, but the advantages which accrue from the system may be held to more than counterbalance the drawbacks. The student is only required by the authorities to attend with due regularity various compulsory classes, to give evidence of diligence in his work, and to conduct himself with proper decorum while within the University precincts. Several halls of residence for students have lately been established, but even here the students are their own masters. Absence of residential colleges implies the absence of college fees, and of the invariable large extras incurred by college life.

The co-existence of teaching and degree-granting universities and extra-mural medical schools in Scotland forms one of the most important factors in the system of medical education in the country. That obtainable at the Universities is the best of its kind, comprising courses on all branches of special medicine and surgery; at the extra-mural schools the special subjects are perhaps even better treated, as they are taught by specialists themselves. In the way of expense, there is little between the University course and the obligatory curriculum for the Licence of the Colleges. The minimum cost for five years' attendance for the licence may be put down at £120, which includes class and examination fees; and at the universities at £146, a difference of about £5 a year only.

Perhaps the one blot upon the Scottish system of medical education at Universities arises from the plan adopted at their professional examinations of delegating the examiners' duties to the professors themselves, along with only one coadjutor for each subject. As University students are now allowed to attend one-half of the total number of courses required for graduation outside the University walls, it happens now and again that those who have done so in a subject, upon which they are examined by the professor teaching it, are placed at a disadvantage in not being thoroughly conversant with subjects specially lectured on by examiners during the preceding session. The examining board for the diploma of the Scottish colleges, indeed, is largely made up of the extra-mural lecturers, but the number assigned to each subject is large enough to avoid the examination of a candidate by his own teacher in the majority of instances.

Apart from the educational attractions offered to students of medicine by the Scottish schools, a very important fact aids to explain the reason why so many students from all parts of the Empire enrol their names in their books: the cost of maintenance is less than in England or Ireland. As a general rule the higher the latitude the cheaper is the living in Great Britain. Edinburgh and Glasgow are more economical than London and Dublin; Aberdeen still less expensive.

THE CARNEGIE TRUST.

Through the munificence of Mr. Andrew Carnegie, LL.D., payment is now made "of the whole or part of the ordinary class fees exigible by the Universities from students of Scottish birth or extraction, and of sixteen years of age or upwards. or scholars who have given two years' attendance, after the age of fourteen years, at State-aided schools in Scotland, or at such other schools and institutions in Scotland as are under the inspection of the Scottish Education Department."

The Trust provides for the payment of the class fees of the above students proceeding to graduation in medicine or science. Application for payment of class fees under the conditions of the Trust should be made to the Secretary, Mr. W. S. McCormick, 2, St. Andrew Square, Edinburgh. By the regulations of the University Commission, one-half of the classes required for University graduation in medicine may be taken extra-murally, and the fees of such extra-mural classes taken in any of the Scotch schools by University students may be paid for by the Trust. In making application for payment of class fees under the conditions of the Trust, students who are desirous of attending classes with lecturers outside the University must state this fact to the Secretary and request to be provided with "Form 2."

UNIVERSITY OF EDINBURGH.

Four degrees in medicine are granted: Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch M.). The first two must be taken together, the last two may be taken separately.

No one is admitted to the degrees of Bachelor of Medicine and Bachelor of Surgery who has not been engaged in medical and surgical study for five years, after passing a preliminary examination in general knowledge in accordance with the medical ordinances. A degree in arts or science of a British or other recognised University is held to supersede such preliminary examination. The subjects included in this general examination are English grammar and composition, English history and geography, Latin, arithmetic, and the elements of mathematics, and, in addition, as optional subjects, Greek, French, or German.

The *annus medicus* of each year is held to be constituted by at least two courses of not less than one hundred lectures each, or by one of such course, and two courses of not less than fifty lectures each, exclusive of the clinical courses, in which lectures are given twice a week during prescribed periods. Two years of the five must be spent at the University, the remaining three years at any University of the United Kingdom, or other Universities or Medical Schools recognised by the University Court.

During the first four years the student must attend elementary botany, elementary zoology, physics, practical chemistry, practical physiology, practical pathology, and medical jurisprudence during courses of not less than 2½ months each; public health, not less than thirty lectures; practical anatomy during two courses of not less than five months each; chemistry, anatomy, physiology, pathology, surgery; materia medica and therapeutics, medicine, and midwifery and the diseases of women and children during courses of not less than five months each. Eight of these subjects must be taken at a University or college affiliated to a University, entitled to grant the degree of M.D. He must attend a course of twenty-five meetings on practical pharmacy in a University or recognised school of medicine, or have dispensed drugs for a period of three months in a hospital or dispensary, or in an establishment recognised by the Pharmaceutical Society. He must attend a nine months' course in clinical medicine and in clinical surgery. During the fifth or final year he must be engaged in clinical study for at least nine months. In all, before graduation he must have attended for at least three years a hospital which accommodates no fewer than 80 patients, and possesses a distinct staff of physicians and surgeons, and he must have acted as clerk in the medical and dresser in the surgical wards of such a hospital, and the practice of a dispensary, or of a physician and surgeon. He must also have had approved opportunities of studying (1) operative surgery, (2) mental diseases at a recognised asylum, (3) at a recognised hospital, post-mortems, fevers, and diseases of the eye, and (4) one of the following: Diseases of children, of the ear, nose and throat, or of the skin, (5) vaccination.

He must personally attend at least twelve cases of labour under the superintendence of a registered medical practitioner, or six such cases, and, for at least three months, the practice of a midwifery hospital in which practical instruction is regularly given.

Every candidate must deliver on or before the date for lodging certificates for the final examination (in 1903, April 16th) to the Dean of the Faculty of Medicine—

1. A delaration in his own handwriting that he has completed his twenty-first year. or that he will have done so on or before the day of graduation, under article of apprenticeship to any surgeon or other master. (This declaration, along with a statement of studies, is appended to the schedule for the final examination, and must be signed before the schedule is given in.)

2. A statement of his studies, as well in literature and philosophy as in medicine, accompanied with proper certificates.

Each candidate is examined both in writing and *viva voce*:—

1. Zoology, botany, physics, and chemistry.
2. On anatomy, physiology, and materia medica, and therapeutics.
3. On pathology.
4. On medicine, surgery, midwifery, forensic medicine, and public health.

The examinations in anatomy. chemistry, physiology, botany, and zoology, materia medica and pathology, are conducted, as far as possible, by demonstration of objects placed before the candidates.

Candidates who are ready to submit to an examination in the subjects comprised in the first division, viz., botany, zoology, physics, and chemistry, may be admitted to examination in all or any two of these subjects at any examination held after they have attended a full course in each of the subjects professed.

Candidates who have passed their examination in the subjects in the first division may go up for examination in those of the second division at the end of their third winter session, but may postpone their examination in materia medica and therapeutics until the close of the summer session following.

Candidates who have passed the first and second divisions may be examined in the third division at the end of the fourth winter session.

Candidates who have passed their examinations in the subjects comprised in the first, second, and third divisions may be admitted to examination in the fourth or final division, when they have completed the fifth year of study.

The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of Bachelor of Medicine and Bachelor of Surgery, and who is of the age of twenty-four years, and who produces a certificate of having been engaged, subsequently to his having received the degrees of M.B. and Ch.B., for at least one year in attendance on a hospital, or in scientific work bearing directly on his profession, or in the Military or Naval Medical Services, or for two years in practice other than purely surgical. The candidate shall submit to the Faculty of Medicine a thesis certified by him to have been composed by himself, and which shall be approved by the Faculty, on any branch of knowledge comprised in the professional examinations for the degrees of Bachelor of Medicine and Bachelor in Surgery, which he may have made a subject of study after having received those degrees. The candidate will also be examined in clinical medicine and must show practical acquaintance with advanced methods of diagnosis; he *may* take, at option, gynæcology, mental diseases, or diseases of children for one of his three cases. The degree of M.D. is conferred on holders of the degrees of M.B. C.M. (old regulations), on the submission of a thesis approved by the Medical Faculty, provided that the candidate shall have passed the medical preliminary examination in the subjects of Greek and logic, or moral philosophy. Should the candidate elect to do so, he may, however, take the M.D. degree under the new regulations, *i.e.*, substituting an examination in clinical medicine for that in Greek and logic. This course is usually pursued by those who did not pass in these subjects with the rest of their preliminary examinations.

The regulations for the degree of Ch.M. are very similar, the candidate being examined in surgical anatomy, operations on the dead body, clinical surgery, and some of the special branches.

Candidates settled abroad, who cannot appear personally to receive the degree, may, after satisfying the Senatus to that effect, have the degree conferred on them *in absentia*.

Fees:—The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is twenty-two guineas, and the proportion of this sum to be paid by a candidate at each division of the examination is registered from time to time in the University Court. The fee for the degree of Doctor of Medicine or of Master of Surgery is ten guineas (old regulations, £5 5s.)

The total expenses of the curriculum, including examination and matriculation fee, is £146.

Bursaries and Scholarships open for Session 1902-1903: Among the bursaries and scholarships open during the ensuing year are:—Town Council Bursaries, some of which may be held in the medical faculty. Early application to the City Clerk, Council Chambers, Edinburgh. McCosh Graduates' Bursary and McCosh Medical Bursary for prosecution of research abroad, tenable for one year. Applications to Dean of Medical Faculty by end of July. Two Mackie Bursaries for students in second and third years, whose pecuniary circumstances need assistance. Applications to Dean by October 1st. Four Buchanan Bursaries. Two Sibbald Bursaries of £30 a year for three years, particulars from Messrs. Mackenzie, Innes, and Logan, W.S., 23, Queen Street, Edinburgh, before September 15th. Two Thomson Bursaries of £25 for four years, one conferred at each preliminary examination in October and March. Five Grierson Bursaries (natives of Crawford and Leadhills have a preference). Names must be sent in before October 1st. Two John Aitken Carlyle Bursaries of £28 for one year for proficiency in class examinations in anatomy and chemistry or physiology. Four Mackenzie Bursaries of £20 in practical anatomy. Renton Bursary of £20, for one year, for students attending classes of natural physiology, mathematics, chemistry, or political economy, who also can show they are in need of pecuniary aid. Names to be sent to Secretary before September 18th. Two Crichton Bursaries of £50, for four years, one competed for at each preliminary examination. Murchison Memorial Scholarship of the interest from £1,000, to take place in Edinburgh in the summer of 1903; Buchanan Scholarship of £40 10s., for proficiency in midwifery and gynæcology, as shown by class work and in the final examination. Other scholarships are:—The James Scott, £42 10s. annually, in midwifery; the Ettles, £31 5s. annually to the most distinguished graduate; two Hope Prizes, £30 annually, in chemistry; two Crichton, £100 annually, in anatomy and physiology. Three Vans Dunlop Scholarships in anatomy and physiology, materia medica and pathology and medical jurisprudence, value £100. Mouat Scholarship in practice of physic, about £55. Thomson Scholarship of £40, for four years, in botany, zoology, and mechanics, for students beginning first winter's session. Apply to Traquair, Dickson, and Maclaren, W.S., 11, Hill Street, Edinburgh, before September 20th. Houldsworth Scholarship in Pharmacology, £40. Syme Surgical Fellowship, £102. Goodsir Memorial Fellowship, £100. Full particulars of these and other prizes may be found in the "University Calendar" (published by Mr. Thin, South Bridge, Edinburgh).

Graduation in Science: The University of Edinburgh also possesses a Faculty of Science which may confer two degrees, Bachelor of Science (B.Sc.), and Doctor of Science (D.Sc.). These degrees are given in pure science and in applied science. Candidates for the degree of B.Sc. in pure science must attend at least seven courses of instruction in the subjects selected by them during the course of not less than three academical years. Three of these courses must be on subjects prescribed for the first science examination, and four on those for the final examination. Four of these courses must be taken in the University of Edinburgh. The subjects for the first science examination are:—1, Mathematics or biology (first professional in medicine not accepted as equivalent to latter); 2, Natural philosophy; 3, Chemistry. For the second examination they may be selected from among the following: Mathematics, physics, astronomy, chemistry, anatomy, physiology, geology, zoology, and botany. Graduates as B.Sc. may, after five years, proceed to the degree of D.Sc., undergoing an examination in the subjects chosen, and presenting a thesis founded on original work.

Graduation in Public Health: Similar degrees are conferred in Public Health. Candidates must be graduates in medicine of a university recognised by the University Court, and must matriculate for the year in which they proceed for examination. Before proceeding to the first examination they must produce evidence that (1) they have worked at least twenty hours a week during a period of not less than eight months, after taking their medical degree, in a recognised Public Health laboratory. Five of these months must be spent consecutively in the Public Health Laboratory of the University of Edinburgh, and (2) have attended a course of lectures on physics in addition to that qualifying for graduation in medicine, and one, of at least three months' duration, on geology, such as the Senatus may approve of.

Candidates for the second examination of B.Sc. in Public Health are not admitted until at least eighteen months have elapsed after having passed M.B., Ch.B., or sooner than six months after the first examination. They must have attended two separate courses of Public Health, of at least forty lectures each, one dealing with medicine, the other with engineering, each in its relation to public health, in such manner as the Senatus shall determine. They must also have studied practical sanitary work under a Medical Officer of Health for six months, have had three months' clinical instruction in a recognised fever hospital, and three months' instruction in mensuration and drawing.

Full details of the subjects included in the different courses are given in the official programme of the Faculty of Science, which may be obtained from the University (price 2d.).

In a similar manner to that described under degrees in pure science, a B.Sc. may after five years proceed to take the degree of D.Sc. in Public Health.

Fees for Science Degrees: B.Sc., first examination, £3 3s.; B.Sc., second examination, £3 3s.; D.Sc., £10 10s.; total, £16 16s.

University Hall, Edinburgh.—In an educational number it is worth while to call attention to the advantages now offered to students coming to Edinburgh to study, in the shape of social residences akin to, though very much less pretentious than, the English University Colleges. During the past six years several buildings have been acquired in Edinburgh for this purpose, in which students can live in a self-governing community. In each house there are private studies with or without bedrooms, and common sitting and dining rooms. The charges vary from 7s. 6d. to 22s. 6d. per week. The residents elect a treasurer from among their number who acts as intermediary between them and the housekeeper or servants. It is a satisfactory indication of the comfort of the Hall that several graduates now live in it and are willing to help or coach the undergraduates for moderate fees. To gain admission two references must be produced from past or present residents. These are considered and voted on at a house meeting. In all disputed points Professor Geddes is the referee, while Dr. Ricardo Stephens is the rent treasurer, who will supply any further information required. The Hall is an admirable place for parents to send their sons to. Any unruly member may be expelled by a meeting of the residents similar to that held for elective purposes.

Medical School for Women.—The Medical Teaching of Women in Edinburgh is carried on by the Scottish Association for the Medical Education of Women (the Secretary, Minto House, Chambers Street). The classes are conducted by the lecturers of the Medical School of the Royal Colleges, and qualify both for the Edinburgh University degree and for the Licence of the Triple Board. The classes are for women alone. The University of Edinburgh does not recognise certificates presented by female candidates for mixed classes without special cause shown. Women students are eligible for the benefits of the Carnegie Bequest.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and an examining body, but admits to examination only those candidates whose course conforms to its own regulations. Within certain limits provision is made for accepting instructions given by recognised medical schools and teachers; but eight of the subjects other than clinical must be taken in this or some other recognised University entitled to confer the degree of M.D., and at least two years of the course must be taken in Glasgow University. Under the new regulations, laid down in Ordinance No. 14, Glasgow No. 1, of the Commissioners under the Universities (Scotland) Act, 1889, four degrees, open both to men and to women are conferred—M.B. and Ch.B. (always conjointly), M.D. and Ch.M. A preliminary examination must be passed in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek French, or German, with possible option to students whose native tongue is not English in the case of the fourth subject, and on passing students must register in the books of the General Medical Council. By a regulation recently enacted, it is no longer compulsory to pass in all the four preliminary subjects at once, and they may now be passed at two stages. For M.B. and Ch.B. a curriculum of five years is required. The curriculum closely resembles that at Edinburgh. The "University Calendar" should be consulted for details.

The fees for M.B. and Ch.B. are £23 2s., and the present fee for hospital attendance is £21. The fee for M.D. is £10 10s., and for Ch.M. is £10 10s.

Bursaries and prizes to the annual amount of about £900 are appropriated to medical students, including an Arthur bursary for women, £25 for three years.

Several bursaries open to students in any faculty are not infrequently held by medical students, and scholarships and fellowships to the annual amount of £1,600 may be held by medical students who have gone through the Arts course.

Queen Margaret College for Women.—Founded in 1883 (by the Glasgow Association for the Higher Education of Women, which was formed in 1877 with the object of bringing university instruction, or its equivalent, within the reach of women), Queen Margaret College in 1890 added to its Faculty of Arts a School of Medicine for Women. This was organised entirely on university lines, and with the view of preparing for university degrees; and when, in 1892, in consequence of the Ordinance of the University Commissioners authorising the Scottish Universities to admit women to instruction and graduation, Queen Margaret College became the Women's Department of the University of Glasgow, its classes in medicine taken previously to its incorporation with the University were recognised as preparing for the degree. A full course of study for M.B. and Ch.B. is given by University Professors and Lecturers, with excellent facilities for hospital and dispensary work in the Royal Infirmary and other hospitals. A Hall of Residence for the students was founded six years ago. Fees for the classes at Queen Margaret College may be paid by the Carnegie Trustees.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen possesses under its charters the amplest privileges claimed or enjoyed by any academical institution. It confers degrees in the five faculties of Arts, Science, Divinity, Law, and Medicine. It also grants diplomas in Public Health, Agriculture, and in Education. It is, moreover, a teaching body equipped with twelve distinct chairs in the various branches of medicine and surgery, besides a Lectureship in Tropical Medicine. The majority of the professors devote their whole time to the work of the chairs. There are fully-equipped laboratories, the accommodation for which has recently undergone considerable extension. The degrees of M.B. and Ch.B. are conferred together; they cannot be obtained separately. The curriculum of study is nearly the same as in the University of Edinburgh; the regulations in the preceding columns will therefore apply here. Two years must be passed at Aberdeen. With regard to fees, each candidate for the degrees of M.B. and Ch.B. must pay a fee of £5 5s. in respect of each of the first three professional examinations, and £7 7s. for the final examination. Class fees, £3 3s. each. Total cost, exclusive of the fees for degrees, is about £100. Besides the Royal Infirmary, students have the opportunity of attending several other local institutions where special courses of instruction are given. Perpetual fee for hospital practice is only £6. The professional examinations are held twice in each year, namely, in March and July, directly after the close of the winter and summer sessions.

Bursaries.—Bursaries, Scholarships, and Fellowships to the number of fifty, and of the annual value of over £1,150, may be held by students of medicine. See "University" Calendar.

The Degree of M.D.—The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of M.B. and C.M. (Old Regulations), is of the age of twenty-four years, and has been engaged subsequently to his having received the degree of M.B. for two years in attendance in a hospital, or in military or naval medical service, or in medical or surgical practice, and has presented a thesis which has been approved of by the Medical Faculty. Candidates for the degree of M.D. (New Regulations) are required to pass an examination in clinical medicine in addition to presenting a thesis. Similar regulations apply to a degree of Ch.M. (Master of Surgery).

A Diploma in Public Health is conferred after examination on graduates in medicine in any university in the United Kingdom. Regulations may be seen in the Calendar, or obtained on application to the Secretary of the Medical Faculty.

Aberdeen Royal Infirmary.—This is a well-equipped institution, containing 240 beds, and affords excellent opportunities for clinical study to students at the Aberdeen University. The city, moreover, offers inducement in the way of cheaper living and comparative quiet to that obtained in Edinburgh and Glasgow, and will doubtless be preferred by some on this account.

ST. ANDREWS UNIVERSITY.

United College St. Andrews and University College, Dundee.

This University (session opens October 9th) grants the degrees of M.B., Ch.B., M.D., and Ch.M. The degrees of the University are open to either sex. For the degree of M.B., Ch.B., two of the five years of medical study must be spent in the University of St. Andrews; the remaining three may be spent in any University of the United Kingdom, or in any foreign, Indian, or Colonial University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. The preliminary examination and the professional examinations are of the same character as in the other Scottish Universities. A Diploma in Public Health is also granted by the University of St. Andrews to graduates in medicine of any University in the United Kingdom. Twelve months must elapse between the date of graduating in medicine and entering for the examinations for the diploma. The course of study required consists of (1) a six months' course of practical chemistry, bacteriology, and the pathology of diseases transmissible from animals to man in a laboratory of the University of St. Andrews; (2) six months work with a medical officer of health; (3) three months clinical instruction in infectious diseases. Subjects for first examination:—Chemistry, physics, bacteriology, and meteorology. Second examination:—Sanitation, sanitary law, vital statistics, medicine in relation to public health.

University College, Dundee, was affiliated and made to form part of the University of St. Andrews on January 15th, 1897, and the whole medical curriculum may be taken in the College. The United College, St. Andrews, offers classes for the first two years of professional study.

Bursaries and Scholarships.

United College, St. Andrews.—Two Berry bursaries of £40 tenable for three years, open to men for arts, science, or medicine. Fourteen Taylor Thompson bursaries £50 to £30 tenable for one year, partly for two, open to women only proceeding to graduate in medicine.

University College, Dundee.—Eleven entrance bursaries of £15, open to women for arts, science, or medicine, tenable for one year. Four £20 and three £15 second year bursaries for men or women in arts, science, or medicine tenable for one year. Four £20 and two £15 third year bursaries for men or women in arts, science, or medicine, tenable for one year. Two Educational Trust Bursaries of £25, tenable for three years. Applicants must have attended a public or State aided school in Dundee for at least one year before examination. Bute Bursary annual income from £1,000 (men only).

Preliminary Examinations.—The dates of the next two examinations are September 27th, 1902, and March 28th, 1903. Schedules (obtainable from the Secretary of the University) to be returned filled up, and fees paid by September 14th, 1902, or March 9th, 1903.

Fees for Degrees.—Total fees for M.B., Ch.B., are the same as at other Scottish Universities, *i.e.*, 22 guineas (payable in instalments). Fee for the degree of M.D., and also for that of Ch.M., is 10 guineas in each case. For the Diploma of Public Health Examinations the fee is £5 5s. for each of the two examinations.

Class Fees.—The fee payable in each of the following separate classes is 3 guineas, viz., in Chemistry, Practical Chemistry, Physics, Zoology, Botany, Physiology, Practical Physiology, Anatomy, Practical Anatomy.

University College, Dundee.—*Class Fees.*—The fee payable in each of the following separate classes is 3 guineas, viz., in Chemistry, Practical Chemistry, Physics, Zoology, Botany, Physiology, Practical Physiology, Anatomy, Practical Anatomy, Materia Medica, Practical Pharmacy, Pathology, Practical Pathology and Bacteriology, Medical Jurisprudence and Public Health, Medicine, Surgery, Operative Surgery and Midwifery.

In Clinical Medicine, Clinical Surgery, Opthalmology, Diseases of Throat and Ear, and Mental Diseases the class fees are 2 guineas each, and in Fevers 1 guinea. For the Chemistry required for the D.P.H. the fee is 7 guineas. A special class is also held for the D.P.H., for which the fee is 3 guineas.

Dundee Royal Asylum.—The appointments include a qualified resident assistant and two resident clinical clerks. Clinical instruction is given.

Further information will be found in the Calendar of the University, published by Messrs. Blackwood and Sons, Edinburgh, or can be had of the Dean of the Medical Faculty, Professor Weymouth Reid, F.R.S.

Dundee Royal Infirmary.—The Infirmary contains 300 beds, with a special ward for the treatment of children. Three resident qualified assistants are appointed annually. Clinical clerks and dressers are attached to the physicians and surgeons, and students are appointed to assist in the post-mortem room. Out-patients are seen daily at 9 a.m. The instruction given at the Infirmary is recognised for purposes of graduation by the Scotch Universities, the University of London, the University of Cambridge, the Royal University of Ireland, and by the Royal Colleges of England and Scotland. Hospital Ticket for the Infirmary, £2 2s each session, or £3 3s. a year. Further information on application to the Medical Superintendent.

THE COLLEGES.

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow have made arrangements by which, after a series of examinations the student may obtain the diploma of the co-operating bodies.

The holders thereof are enabled to register three diplomas under the Medical Acts, viz., Licentiate of the Royal College of Physicians of Edinburgh, Licentiate of the Royal College of Surgeons of Edinburgh, and Licentiate of the Faculty of Physicians and Surgeons of Glasgow. The diplomas are also recognised by the Army, Navy, and other public bodies.

The three co-operating bodies grant their *single* qualifications only to candidates who are already registered as possessing another and opposite qualification in medicine and surgery, as the case may be.

Regulations of the Conjoint Board of the Royal College of Physicians of Edinburgh and the Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons, Glasgow.—The candidate must produce certificates of having attended the following separate and distinct course of lectures, the certificate distinguishing the sessions and the schools in which the courses were severally attended. Anatomy, one course, six months. Practical anatomy, twelve months. Chemistry, one course, six months. Practical or analytical chemistry, one course, three months. Materia medica, one course, three months. Physiology, one course, six months. Practice of medicine, one course, six months. Clinical medicine, nine months. Principles and practice of surgery, one course, six months. Clinical surgery, nine months. Midwifery and diseases of women and children, one course, three months. Medical jurisprudence, one course, three months. Pathological anatomy, one course, three months. The candidates must also produce the following certificates:—(*a*) Of having attended not less than six cases of labour under the superintendence of the practitioner who signs the certificates, who must be a registered medical practitioner. (*b*) Of having attended for three months, instruction in practical pharmacy. The certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the Superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicine to his patients, or a teacher to a class of practical pharmacy. (*c*) Of having attended for twenty-four months the medical and surgical practice of a public general hospital, containing on an average at least eighty patients, and possessing distinct staffs of physicians and of surgeons. (*d*) Of having attended, for six months, the practice of a public dispensary specially recognised by any of the co-operating bodies; of having been engaged for six months as visit-assistant to a registered medical practitioner. (*e*) Of having been instructed in vaccination.

First Examination, Fee £5.—The first examination shall embrace chemistry, comprising the following particulars:—Chemical physics, heat, light, and electricity; the principal non-metallic and metallic elements, and their more common combinations, also the leading alcohols, organic acids, ethers, carbohydrates, and alkaloids; the candidates will also be examined practically in testing; physics and elementary biology. The first examination shall take place not sooner than the end of the first year, including a winter and summer session. Candidates who desire to enter for the first professional examination must apply to the Inspector of Certificates on or before the Friday preceding the day of examination, and must produce certificates of attendance on one course of chemistry, one course of practical chemistry, one course of anatomy, and six months' practical anatomy.

Second Examination, Fee £5.—The second examination shall embrace anatomy and physiology, and shall not take place before the termination of the summer session of the second year of study. Candidates must produce to the inspector certificates of attendance on the prescribed courses of anatomy, practical anatomy, and physiology.

Third Examination, Fee £5.—Comprises the subjects of pathology, materia medica, and pharmacology and advanced anatomy.

Final Examination, Fee £15.—The final examination shall embrace the principles and practice of medicine (including therapeutics and medical anatomy, clinical medicine); the principles and practice of surgery (including surgical anatomy and surgical pathology); clinical surgery; midwifery and gynæcology, medical jurisprudence and hygiene; and shall not take place before the termination of the full period of study.

Subjects of Preliminary Education: (1) English language, including grammar and composition; (2) Latin, including grammar, translation from specific authors, and translation of easy passage not taken from such authors; (3) elements of mathematics, comprising (*a*) arithmetic, including vulgar and decimal fractions; (*b*) algebra, including simple equations; (*c*) geometry, including the first two books of Euclid; (4) elementary mechanics of solids and fluids, comprising the elements of statics, dynamics, and hydrostatics; (5) one of the following optional subjects:—(*a*) Greek; (*b*) French; (*c*) German; (*d*) Italian; (*e*) any other modern language; (*f*) logic; (*g*) botany; (*h*) zoology; (*i*) elementary chemistry.

Qualification in Public Health: The College of Physicians, in association with the Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, confers a certificate of competency in public health. The examinations are held in April and October. Fee, £10 10s.

For the special regulations of the Royal College of Surgeons of Edinburgh, intending candidates should apply to Mr. James Robertson, 48, George Square, Edinburgh; and for those of the Royal College of Physicians, to Dr. R. W. Philip, 45, Charlotte Square, Edinburgh.

The Fellowship of the Royal College of Physicians of Edinburgh is conferred only by election, and the candidate must have been a member of the college for at least three years previously, and have attained the age of twenty seven years.

The membership is conferred only on a licentiate of a college of physicians or graduate in medicine of a British or Irish university provided he shall have attained the age of twenty-four years and shall have passed an examination (1) On the principles and practice of medicine, including therapeutics; (2) on one of the following subjects to be selected by the candidate, *in which a high standard of proficiency is expected:—(a)* one or more departments of medicine specially professed; *(b)* psychological medicine; *(c)* pathology; *(d)* medical jurisprudence; *(e)* public health; *(f)* midwifery; *(g)* gynæcology. The examination is of a searching character extending over three days, the first of which is devoted to the examination of patients, *viva voce* and practical examination on methods of diagnosis —*e.g.*, microscopy of blood, clinical bacteriology, quantitative analysis, &c., and written commentary on a case examined. The second day is taken up by written papers, and the third by practical examination on special subject and orals.

The fee for membership is 35 guineas, for fellowship 38 guineas, with a stamp duty of £25—£101 13s. in all.

The licence, or single qualification in medicine, is conferred on candidates who already possess a recognised qualification in surgery. The examinations of this licence are held on the first Wednesday of each month, save those of September and October, on medicine, materia medica, midwifery, and medical jurisprudence. The fee is £15 15s., and intending candidates should communicate with the Secretary of the College at least eight days before the date of examination.

The Fellowship of the Royal College of Surgeons of Edinburgh is conferred (except under certain conditions as to age and professional standing) only on candidates who have passed a special examination, and have previously obtained a diploma from the college, or from either of the Colleges of Surgeons of England or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, or the surgical degrees of the Universities of Great Britain, and who are twenty-five years of age. The subjects for examination for those who are already Licentiates of the College are on the principles and practice of surgery, clinical and operative surgery, and one optional subject.

Those who are not Licentiates of this College: on principles and practice of surgery, clinical and operative surgery, surgical anatomy, and one optional subject; and in such supplementary subjects as have not, in an adequate manner, been included in the examination for the registrable surgical qualification possessed by such candidates, and which are required in the examination for Licentiates of this College.

The optional subjects shall embrace: (*a*) Surgery, special branches; (*b*) advanced anatomy and physiology; (*c*) surgical pathology and morbid anatomy; (*d*) midwifery and gynæcological medicine and surgery; (*e*) medical jurisprudence and hygiene; (*f*) practice of medicine and therapeutics. The examinations are written, oral, and practical. Three weeks' notice must be given to Mr. James Robertson, from whom full particulars as to certificates required may be obtained. The fee is £30 for those who hold the diploma of Licentiate of the College, and £45 to others (no stamp duty is payable on the diploma). Registered practitioners, aged not less than 40, who have been in practice for not less than ten years, and who have highly distinguished themselves by original investigations, may under special circumstances be elected without examination. Women are not admitted to the Fellowship.

Licence.—The examination embraces the principles and practice of surgery (including operative surgery and surgical pathology), clinical surgery, and surgical anatomy, and shall not take place before the termination of the full period of study. Fee £15 15s.

Wood Bursary.—The examination for the Wood Bursary, of £60 per annum, tenable for three years, will take place on October 21st and 22nd, at the college. The subjects will be found in our advertising columns.

Dental Diploma.—Every candidate for the dental diploma must have attended the general lectures and courses of instruction required at a university or an established medical or dental school recognised by the College as qualifying for the diploma in surgery. The fee is £10 10s.

Edinburgh Royal Infirmary.—Clinical instruction is afforded at this institution, which contains 780 beds in the building, and 10 beds in a convalescent home under the supervision of professors of the university, and the ordinary physicians and surgeons of the infirmary. Special instruction is given on diseases of women, physical diagnosis, and diseases of the eye, ear, throat and teeth, Separate wards are devoted to venereal diseases, diseases of women, diseases of the eye, also to cases of incidental delirium or insanity, and three wards are specially set apart for clinical instruction to women students. Post-mortem examinations are conducted in the anatomical theatre by the pathologists, who also give practical instruction in pathological anatomy and histology. The perpetual fee, on one payment, £12; the annual fee, £6 6s.; half-yearly £4 4s.; quarterly, £2 2s.; monthly, £1 1s. Separate tickets amounting to £12 12s. entitle the student to a perpetual ticket. No fees are payable for any surgical or medical appointment.

The appointments are as follows:—

1. Resident physicians and surgeons are appointed and live in the house free of charge. There is no salary. The appointment is for six months, but may be renewed at the end of that period by special recommendation.

2. Special non-resident clerks (in the special subjects and for out-patient work) are appointed for six months. These also may be similarly renewed.

3. Clerks and dressers are appointed by the surgeons and physicians. These are open to all students and junior physicians holding hospital tickets.

4. Assistants in the pathological department are appointed by the pathologists to conduct post-mortem examinations in the anatomical theatre.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, EDINBURGH.

The government of this school, established in 1505, is now vested in a board which is equally representative of the two Royal Colleges and the Lecturers, the school being styled "The School of Medicine of the Royal Colleges, Edinburgh." Each lecturer on a qualifying subject is required to pass a special examination before he is licensed by the Royal College to which he belongs, and in order to give a course qualifying for University graduation he must further be recognised by the University Court. In every case, the lecturer must satisfy the Royal Colleges and the University that he has adequate rooms and appliances for the teaching of his special branch of study. The present number of lecturers is fifty-seven, of whom the greater number deliver qualifying courses of instruction of the same duration and scope as those delivered within the University, while a large number of non-qualifying courses on special subjects of interest to medical science, but which are not required for graduation, are delivered both in the winter and summer sessions. The students who attend the classes of the School of Medicine are largely students proceeding to the University degree, as well as those who are intending to take other qualifications, such as the triple qualification of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow; that of the Royal College of Physicians of London, and the Royal College of Surgeons of England, and the degrees of the different Universities. The number of students attending the school averages 1,300 annually. Courses of lectures on special non-qualifying branches of study have for the last quarter of a century formed a marked feature of the school. In Edinburgh such special subjects could only be studied extra-murally until the University recently appointed from the teachers of this school lecturers on diseases of the eye, insanity, and diseases of children to conduct classes in the University.

The minimum cost of the education in the School of Medicine for the triple qualifications of physician and surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the joint examinations, is about £115, which is payable by yearly instalments during the period of study.

The Winter Session opens October 1st. The secretary, Mr. R. N. Ramsay, 24, Forest Road, Edinburgh, will forward the School Calendar *gratis* to inquirers.

GLASGOW EXTRA-MURAL SCHOOL.

St. Mungo's College and Glasgow Royal Infirmary.—This college was incorporated in 1889 under its new title, being formerly known as the Glasgow Royal Infirmary School of Medicine. The Medical Faculty occupies buildings erected for the purposes of the medical school in the grounds of the hospital, and the laboratories, museums, and lecture rooms are of the most approved description. Attendance on the classes in St. Mungo's College qualifies for the medical degrees of the Universities and the medical and surgical colleges in accordance with their regulations.

The Royal Infirmary, which is at the service of the College for teaching purposes, is one of the largest general hospitals in the kingdom. It has 612 beds available for clinical instruction, including an ophthalmic department, and it has special wards for diseases peculiar to women, for venereal diseases, erysipelas, burns, and diseases of the throat. At the dispensary special advice and treatment are given in diseases of the eye, ear, teeth, and skin, in addition to the large and varied number of ordinary medical and surgical cases—about 62,000 per annum—which in a great industrial centre daily require attention. Students at the college and hospital get the benefit of dispensary experience free of charge, and no better or wider field for seeing hospital practice and receiving clinical experience can be found than in the Glasgow Royal Infirmary.

Appointments.—All appointments are open. There are five physicians' and seven surgeons' assistants, who obtain free board and residence in the hospital and act in the capacity of house physicians and house surgeons, and there is an assistant to the gynæcologist, who boards but does not reside in the hospital. There is also a house surgeon for the ophthalmic department. These appointments are made for six months, and are open to gentlemen who have a legal qualification in medicine and surgery. Clerks and dressers are appointed by the visiting physicians and surgeons. From the large number of cases of acute diseases and accidents of varied character received, these appointments are valuable to students. In the pathological department assistants are also appointed by the pathologist.

Fees.—The fees for Lectures, including Hospital attendance necessary for candidates for the Diplomas of the English, Scotch, and Irish Colleges of Physicians and Surgeons, amount to £72.

Anderson's College Medical School, Glasgow.—New and excellently equipped buildings were opened in October, 1877, in Dumbarton Road, immediately to the west of the entrance to the Western Infirmary, and within four minutes' walk of the University. Extensive laboratory accommodation is provided for practical anatomy, practical chemistry, practical botany, practical zoology, practical physiology, practical pharmacy, operative surgery. There are also provided a library and reading room, and a students' recreation room. The buildings are constructed upon the most approved modern principles. The dissecting room is open in winter from 9 a.m. to 6 p.m., and in summer from 6 a.m. to 6 p.m. These students are assisted in their dissections by the professor and demonstrators, by whom daily examinations and demonstrations on the parts dissected are conducted. The supply of subjects is ample, and students are consequently provided with parts as soon as they may be ready for them. The dissecting room is provided with a complete series of dissecting specimens mounted in plaster of Paris illustrating the anatomy of the human body. There is also a large Bone Room, furnished with complete sets of painted and unpainted bones.

Class Fees.—For each course of lectures (anatomy, ophthalmic medicine and surgery, aural surgery, diseases of throat and nose, and mental diseases excepted), first session, £2 2s.; second session (in Anderson's College), £1 1s.; afterwards free. For practical classes (except anatomy), viz., chemistry, botany, zoology, physiology, pharmacy, operative surgery, first session, £2 2s.; second session, £2 2s.

Anatomy Class Fees.—Winter: First session (including practical anatomy), £4 4s.; second session (including practical anatomy), £4 4s.; third session, £2 2s. To those who have had the necessary courses of practical anatomy, the fee will be £1 1s. Summer: Lectures and practical anatomy, £2 12s. 6d.

Western Infirmary.—Fees: For hospital attendance, first year, £10 10s; afterwards free. For each clinical class, in winter, £3 3s.; in summer, £2 2s. After three such annual payments of £5 5s the fee for each clinical class will be £1 1s. Pathology, each course, £3 3s. Vaccination fee, £1 1s.

Royal Infirmary.—Fees: Hospital practice and clinical instruction, first year, £10 10s.; second year, £10 10s.; afterwards free. Six months, £6 6s.; three months, £4 4s.; pathology, both courses, £4 4s.; vaccination fee, £1 1s.

Dental Curriculum.—Students studying with a view to the dental diploma can obtain instruction in the following subjects: Physics, chemistry, anatomy, physiology, surgery, practice of medicine, and materia medica. The special dental courses may be obtained in the Dental School, 5, St. Vincent Street, Glasgow.

POST-GRADUATE COURSES IN SCOTLAND.

In Edinburgh a number of post-graduate courses continue more or less throughout the year. Among them are:

1. Ophthalmology: Daily at the Royal Infirmary. 2. Ophthalmoscopy: Dr. George Mackay, Eye Dispensary,

Lauriston Place, fee £2 2s.; Dr. W. G. Sym, Eye, Ear, and Throat Infirmary, Cambridge Street, fee £2 2s.; Mr. J. V. Paterson, Eye, Ear, and Throat Infirmary, Cambridge Street, fee £2 2s. 3. Aural Surgery, &c,: Dr. Macbride and assistants, Royal Infirmary; Dr. Hunter Mackenzie, Eye, Ear, and Throat Infirmary, fee £2 2s.; Dr. Logan Turner, Surgeons' Hall. 4. Pathological Bacteriology: Dr. T. Shennan, Surgeons' Hall, fee £3 3s.; Dr. Taylor Grant, Lindsay Place; Dr. Stuart McDonald, New School, Bristo Street; Dr. Russell, Minto House. 5. Dermatology; Drs. Allan Jamieson and Norman Walker, fee £3 3s.; Dr. Stewart Stirling, Skin Dispensary, Lauriston Place, fee £2 2s. 6. Diseases of Children: Sick Children's Hospital. 7. Chest diseases: Dr. R. W. Philip, 26, Lauriston Place, fee £2 2s.; Dr. G. Lovell Gulland, 26, Lauriston Place. 8. Gynæcology; Dr. Brewis, fee £2 2s.; Dr. J. Harg Ferguson, Leith Hospital. 9. The Demonstrations on Modern Gastric Methods, by Dr. A. Lockhart Gillespie, fee £2 2s., available at any time during the year on the request of a sufficient number of post-graduates. 10. Advanced Gynæcology and Microscopical Pathology: Dr. Berry Hart, Surgeons' Hall. 11. Medical Electricity: Dr. Dawson Turner, Surgeons' Hall. 12. Neurology: Dr. J. J. Graham Brown, New School; Dr. Alexander Bruce, Surgeons' Hall.

In Glasgow, special courses in ear diseases are held in November and May at Anderson's College, and Post-graduate courses in pathology and bacteriology at the University in autumn.

End of the Educational Number.

THE OPENING OF THE MEDICAL SCHOOLS.

Charing Cross Hospital Medical School—Wednesday, Oct. 1st. Introductory Address by Prof. W. H. Welch, M.D.
Dental Hospital of London - Wednesday, Oct. 1st.
Guy's Hospital Medical School—Wednesday, Oct. 1st, 3 p.m. Distribution of Prizes by the Lord Mayor of London.
King's College. London, Medical Faculty - Wednesday, Oct. 1st.
London Hospital Medical College—Wednesday, Oct. 1st
Middlesex Hospital Medical College—Wednesday, Oct. 1st. Introductory Address by Mr. Stephen Paget, M.A., F.R.C.S, 3 p.m.
Royal Free Hospital School of Medicine for Women—Wednesday, Oct. 1st. Introductory Address by Charles Burt, Esq., 4 p.m.
St. Bartholomew's Hospital and College—Wednesday, Oct. 1st.
St. George's Hospital Medical School Wednesday. Oct. 1st, at 4 p.m. Introductory Address by Dr. T. T. Whipham.
St. Mary's Hospital Medical School - Wednesday, Oct. 1st.
St. Thomas's Hospital Medical College - Wednesday, Oct. 1st.
University College Medical School—Wednesday, Oct. 1st.
Westminster Hospital Medical School—Wednesday, Oct. 1st.

Provinces.

University of Birmingham—Wednesday, Oct. 1st.
Bristol, University College—Wednesday, Oct. 1st.
Cardiff, University School of Medicine—Friday, Oct. 10th. Opening Address by Dr. D. Berry Hart.
Durham University School of Medicine—Wednesday, Oct. 1st.
Liverpool University College—Wednesday, Oct. 1st.
Manchester, Owens College—Wednesday, Oct. 1st. Introductory Address by Sir Dyce Duckworth. 4 p.m.
Sheffield, University College—Tuesday, Sept. 30th. Introductory Address by Sir H. G. Howse.
The Yorkshire College—Wednesday, Oct. 1st.

Ireland.

Adelaide Medical and Surgical Hospitals, Dublin.
Catholic University Medical School. Dublin—Nov. 2nd.
City of Dublin Hospital—Wednesday, Oct. 1st.
Dr. Steeven's Hospital—Tuesday, Oct. 7th.
Dublin University—Wednesday, Oct. 1st.
Meath Hospital—Wednesday. Oct. 1st, at 4.30 p.m.
Mercer's Hospital- Wednesday, Oct. 1st.
St. Vincent's Hospital—Wednesday, Oct. 1st. Introductory Lecture by Mr. McArdle.
Queen's College, Cork—Tuesday, Oct. 21st.
Richmond, Whitworth, and Hardwicke Hospitals—Wednesday, Oct. 1st.
Royal College of Surgeons in Ireland Schools of Surgery—Wednesday, Oct. 1st.
Trinity College School of Physic, Dublin, Dissecting Rooms, &c.—First week in October: Lectures begin first week in November.

Scotland.

Aberdeen University—Tuesday, Oct. 14th.
Dundee University College—Wednesday, Oct. 15th.
Edinburgh University—Tuesday, Oct. 14th.
Edinburgh School of Medicine, Rooms, and Laboratories—Wednesday Oct 1st.
Glasgow, Anderson's College Medical School.—Thursday, Oct. 16th.
Glasgow, Queen Margaret College School of Medicine for Women—Oct. 16th.
Glasgow University—Thursday, Oct. 16th.
Glasgow, St. Mungo's College—Thursday, Oct. 16th.
Glasgow Royal Infirmary—Thursday, October 16th.
Royal Colleges, Edinburgh—Tuesday, Oct. 14th.
St. Andrew's University—Wednesday, Oct. 15th.

Notes on Current Topics.

The General Medical Council Election.

The voting papers for the election to fill the place on the Council rendered vacant by the expiration of the term of office of Sir Victor Horsley have been sent out, and must be returned by the 19th instant. Mr. Joseph Smith, of Chiswick, is a candidate in opposition to the retiring member. He comes forward as the nominee of the Incorporated Medical Practitioners' Association, and as a protest against the seats allotted to the direct representatives being filled by consultants instead of by general practitioners. The principle is one which has our hearty sympathy and approval, but under present circumstances it is impossible to ignore the valuable services to the profession rendered by Sir Victor Horsley during his tenure of office, and the still more valuable services which it will be within his power to render should he, as we anticipate, be re-elected. It is to be hoped that practitioners will make a point of recording their votes, so that it may not be asserted that they are indifferent to the future conduct of the Council.

Poison-Selling Abuses in Glasgow.

An unqualified chemist's assistant at Glasgow was proceeded against last week for having infringed the Pharmacy Acts by selling oxalic acid. The defendant's solicitor pleaded a novel and not very successful defence, stating that the acid was "sold every day by chemist's assistants," in fact, he himself had purchased thirteen samples of the poison from unqualified assistants. Naturally this defence failed in its object, but it ought to encourage the Pharmaceutical Society to pursue the campaign with renewed ardour until no such allegation be possible.

Wholesale Ptomaine Poisoning.

From time to time the medical profession is sharply reminded of the fact that its range of knowledge is limited in many directions. A ready means of detecting the presence of poisonous ptomaines in a pie, for instance, remains to be discovered by some benefactor of the human race. For a test of the kind, it need hardly be remarked, is a necessary first step towards the prevention of the particular danger in question. It has long been known that pies were specially prone to become poisonous, especially those savoury articles prepared from rabbit and veal or pork. Science at length discovered that the contamination arose from bacterial invasion, with the subsequent formation of ptomaines, and there the matter rests for the present. One of the most extensive epidemics hitherto recorded has just occurred in Derby, where some 150 persons have been poisoned by eating pork pie. Three deaths have resulted, one of them in London and another in Uttoxeter, whither portions of Derby pie had been carried home and consumed. In one instance poetical justice is said to have overtaken a junior attendant in a public office, who ate a portion of a sample that had been procured for analysis.

That kind of test is obviously somewhat crude for practical laboratory purposes, besides being too slow a process. There can be little doubt that sooner or later bacteriologists will devise some quick and simple method of determining the presence of injurious ptomaines in food. Then, and not till then, will it be possible effectually to supervise the large and important industry which supplies the public with meat pies.

A Pharmaceutical Innovation.

The inconvenience which purchasers of both sexes must experience in having to formulate their requirements "cheek by jowl" at the same counter in the retail chemist's shop is obvious. There are numerous articles and cosmetic appliances, peculiar to one and the other sex, which are, so to speak, confidential requirements; yet, under the existing conditions of retail pharmacy, no degree of privacy is obtainable. *Nous avons changé tout cela.* A chemist who recently set up in business at Opelousas, a thriving city or village "out West," has introduced a change with some claim to originality. It is practically a double-shop, with two entrances, labelled respectively "Ladies" and "Gentlemen." The interior is similarly partitioned off, and the ladies' department is in charge of a female pharmacist. This innovation has much to recommend it, and it is certainly not asking too much of our pharmacists to suggest the propriety of allocating a certain counter space to their lady customers, with, whenever practicable, a lady dispenser to minister to their wants.

International Congress on Tuberculosis.

The next International Conference on Tuberculosis will be opened at Berlin on October 22nd, terminating on the 26th. The principal topics which will engage the attention of members are (1) the position of the State in regard to the prevention of consumption, (2) the notification of consumption, (3) the education of school children in the elementary principles of the causation and prevention of the disease, (4) precautions to be taken to prevent the spread of the disease by milk, (5) the consideration of tuberculosis in infancy, (6) the protection of workpeople in respect of the prevention of consumption, (7) the classification of consumptives and the various methods of providing accommodation for them. Communications concerning papers intended to be read at the Congress should be addressed forthwith to the offices of the International Committee, 2, Wilhelm Platz, Berlin.

A decree has been promulgated in Hungary forbidding the practice of massage except by duly qualified medical practitioners.

Mr. John Croft, F.R.C.S., has resigned his appointment as one of the two medical officers of the National Provident Institution, a position which he has held for the last eighteen years.

Dr. T. S. Kerr, Principal Civil Medical Officer of the Straits Settlements, is reported to be returning to England on sick leave in order to undergo an operation.

The authorities of the Isle of Wight County Asylum have elected Miss Wilkinson, M.B., of Edinburgh, to the vacant office of assistant medical superintendent.

Is Cancer on the Increase?

Prof. de Bovis, of Rheims, has published an exhaustive study on the alleged progressive frequency of cancer, of which the following is a *résumé*:—

For a long time medical men and statisticians are not weary in repeating that cancer increases in frequency every year. An American surgeon has even said that, "if the same rate of mortality is maintained for ten years hence, there will be in the state of New York more deaths from cancer than from phthisis, small-pox, and typhoid fever taken together." It must be admitted that the statistics justify amply these pessimistic predictions; in the last twenty years the mortality from cancer has doubled or tripled according to the countries, as the following statistics would show. Out of 100,000 inhabitants England furnished in 1880, 51·1, and in 1900, 82·9; France (Paris), 98·2, 121; Holland, 50·1, 95·9; Ireland, 34·3, 58; Norway, 43·0, 85·0; United States, 35·4, 66·4; Scotland, 46·5, 88. If it were necessary to follow up the question to a much earlier date it would be found that in England cancer caused but 17·7 deaths in 1840 per annum and per 100,000 inhabitants; Norway 19 in 1865, against 85 in 1897. All the above statistics show a rapid increase in the frequency of cancer, but a question might be asked: is this increase real or only apparent? The partisans of the latter opinion, King, Newsholme, Andrew, attribute the increase to three factors—imperfection of earlier statistics, increase of human longevity, progress of clinical research. The reproach addressed to statistics was in part justified, yet taken altogether they deserved a certain confidence. The second cause was of little or no value, while the third appeared to be more or less sustained by the fact that between the years 1875-1880 considerable progress was made in the diagnosis of cancer of the stomach, and since then the liver, intestines, spleen, pancreas have had by turns their "golden age," medical or surgical, but it should be remembered that such cases probably always existed, although ignored by the clinician. To solve the problem figures are necessary. King and Newsholme were the first to study this point. In examining the statistics of the city of Frankfort on the Maine, they addressed themselves particularly to *accessible* cancers (uterus, breast, tongue, rectum, skin), that is to say, those which could be diagnosed formerly as well as to-day, to determine if they had increased in the same proportion as *inaccessible* cancer (stomach, liver, &c.). The result of the mortality of their calculation was as follows:—From 1860-1889 accessible cancers in men had passed from 12·6 to 7·4 per 100,000 inhabitants, that of women from 108·1 to 132·9; the increase was consequently slight. On the other hand, the inaccessible cancers in men had progressed for the same period from 111·8 to 188·8, and in women 132·3 to 193, that is to say, the increase was much more considerable than for accessible cancer. From 1890 to 1899 the mortality of genital cancer in women fell from 76 to 74 per 100,000 women over twenty years of age. At Vienna the mortality of genital cancer in the female fell in ten years (1872-1882) from 162 to 133. Here the decrease is very marked. The statistics of other large cities, Chicago, Berlin, Brussels, Hamburg, Paris, established the same fact, that uterine cancer tended to diminish rather than to increase. If consequently it is proved that external or accessible cancer is at least stationary, must it be concluded that visceral or inaccessible cancer had not increased either, and that their apparent increase was solely due to clinical progress? An affirmative answer might be made without hesitation to the question, if at our day it was proved that cancerous receptivity remained the same for all the organs, but of that nothing is known. In any case it is legitimate to suppose that the transformations of social life, alcoholism, nicotism, and many other causes have rendered our visceræ *loci minoris resistentiæ* much more vulnerable than the external organs.

The above statistics and considerations would justify the following conclusions :—

1. External cancer is stationary.
2. Visceral cancer seems to be on the increase.

As regards the relative frequency of cancer in both sexes, it is the general belief that the women are more prone to contract the disease than men, but the latest statistics concerning the kingdom of Prussia (1900) have shown that the two sexes possess an almost equal cancerous receptivity—100 men for 101 women. According to a table drawn up by Wutzdorff, women present a higher mortality from cancer than men between the ages of twenty-five and fifty, from fifty to sixty the mortality is about the same, but after sixty years the men take the lead.

The period between twenty-five and fifty, representing that of genital activity of the woman, it is natural to suppose that genital cancer is responsible for the unequal division of cancer in the course of the lives of both sexes.

In concluding his article, M. de Bovis said that one thing appeared to him certain, and that is, the attentive examination of statistical documents contradicts more than it confirms the frightful increase of cancerous affections alleged by the majority of authors, and in any case, if there be really an increase, it is not sufficient to create alarm in the public mind.

Austria.

Sea Sickness.

Weitlauer has been making further experiments on board the Austrian steamships in order to relieve the sea sickness which prevails during rough weather. Clinical observation leads him to conclude that the vomiting is due to the concentration of sensation in the stomach at the time when the ship is making the descent or when about to descend, which he compares to the febrile state. Many of the gastric "pelottes" give relief but do not cure the disease. A very good preparation is antipyrine with caffeine and cocaine, also quinine.

He has constructed an instrument to measure the oscillation, and finds that when the vertical elevation does not exceed nine or ten inches five or ten times in the minute the sickness does not occur. The worst effects are produced when the oscillations range between one-half and two metres nine to twelve times per minute.

He concludes by saying that the symptom is produced by the repeated wave pressure of the fluids against the soft and hard parts of the body where the specific gravity differs. He thought this variation of weight acting on both brain and stomach was the primary cause of the sickness.

Scrofula.

Professor Cornet, in Nothnagel's series, distinguishes scrofula from tubercle. The former may be a mild form of the latter, but is distinguished by the transparent thin skin with prominent veins and a skin in which the lymph passes more easily than in tubercle, which is seen to greater advantage in the child than the adult.

Scrofula is divided into the tuberculous form, non-tuberculous, or pyogenic, and the mixed form. In the first the tubercle bacilli are alone found ; in the second, the real exciters are the staphylococcus pyogenes aureus and albus, and the streptococcus pyogenes, while in the third form these two forms are associated. The non-tuberculous form, is the most striking, in having the transparent skin and mucous membrane. This feature he attributes to the size of the tubercle bacillus being smaller and thus it is able to burrow deeper into the finer structures. The non-tuberculous form is more frequently met with in the young female than in the male, and may be of toxic origin.

The influence of heredity in scrofula is just as marked as in tubercle, and may be traced for generations back. The treatment is fresh air, good food, and hygienic attention ; the same, in fact, as for tuberculosis.

THE GENERAL MEDICAL COUNCIL ELECTION. —TO RETAIN THE INVALUABLE SERVICES OF SIR VICTOR HORSLEY.

To the Editor of The Medical Press and Circular.

Sir,—The bare idea of *any* man opposing so powerful a member of the General Medical Council, and so ardent a reformer as Sir Victor Horsley has proved himself probably seems ridiculous, and at sight the result of the present contest is perfectly obvious, but I wish to remind your readers that the most popular candidates for Parliamentary honours have again and again been defeated by the over-confidence of their admirers and supporters.

Will you allow me to urge upon the electors to promptly fill up their voting papers in favour of Sir Victor Horsley, and thus make sure of the return of the only man who has ever grasped the question of medical reform effectively, and who is the first man of high position we have found to fight for the rights of general practitioners.

It is absolutely necessary to give an effective quietus to the wholly unwarrantable meddling of Mr. George Brown, who is solely responsible for the cost, trouble, and, to a huge majority of the electors, annoyance of a contest.

I am, Sir, yours truly,
Jas. Brassey Brierley.

P.S.—Vote at once for Sir Victor Horsley.—J. B. B.

Literature.

AIDS TO DENTAL ANATOMY AND PHYSIOLOGY. (*a*)

In this second edition Mr. Underwood has made his little book one of the best of its class. It is, as he intends it to be, not merely a cram-book, but an introduction to the study of dental histology, and a real aid in the study of dental anatomy and physiology generally. The student will do well to master Mr. Underwood's pages before turning to larger text-books. So prepared, the student will have no difficulty in completing his knowledge of the subject, and facing his examiners with confidence. Mr. Underwood's long practice as a teacher has enabled him to acquire the art of giving the quality of objectivity to his writing, and his descriptions of the complex physiological processes of dental histogenesis are made easily comprehensible to the student of average intelligence. The book is notably free from a fault of other similar works, which too often lump together the opinions of pseudo-scientific pretenders with the work of recognised authorities. We are, however, not quite certain in what category of writers Heitzmann and Bödecker deserve to be placed ; but we do think Mr. Underwood's book would not lose in value if reference to these investigators were omitted in future editions.

(*a*) "Aids to Dental Anatomy and Physiology." By Arthur S. Underwood, M.R.C.S., L.D.S., Professor of Dental Surgery at King's College, London ; Member of the Board of Examiners in Dental Surgery, Royal College of Surgeons of England. London : Baillière, Tindall and Cox. Second Edition. Price 2s. 6d.

Notices to Correspondents, Short Letters, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

NOTICE TO HOSPITAL AND COLLEGE DEANS.

The Editor desires to thank those gentlemen attached to the various Medical Schools and Hospitals for supplying him with the information from which the foregoing pages have been composed.

NOTICE TO OUR READERS.

As this number is mainly devoted to information necessary for students intending to join one or other of the various Medical Colleges, and for those who, having passed their curriculum, are about to enter the ranks of the profession, much of the ordinary matter which usually fills our columns is necessarily deferred till next week.

GRATUITOUS COPIES.

A very large number of copies of this issue are being sent gratuitously to all the educational establishments, hospitals, reading-rooms, clubs, and large hotels in the United Kingdom, and to a large number in America, India, the Colonies, and on the Continent; should any of our readers desire to present a copy to a patient or friend who contemplates sending his son to a medical school, our Publisher will be happy to supply him with a duplicate free of cost on receipt of address.

A. R. F.—The proportion is by no means as high as you suppose. According to the recent census the proportion of blind persons in Scotland is ·72 of the population (1 in 1,375). The deaf and dumb were in the proportion of 1 to 1,695.

DIAGNOSIS BY EXCLUSION.

"There is nothing the matter with you," persisted the Eddyite, "absolutely nothing. Can I not convince you?" "Let me ask you a question," replied the sick man. "A thousand, if you like." "Well, suppose a man has nothing the matter with him, and he dies of it, what didn't he have the matter with him?"—*Philadelphia Press.*

T. Hamilton.—You had better divide the tendo Achillis subcutaneously and put the foot up in plaster of Paris. You may then, after the tendon has been lengthened and the heel brought down, divide some of the other tendons. If you do not feel justified in attempting that, send the case to an orthopædic surgeon. Nowadays that branch has attained a great pitch of perfection.

Historicus.—The crimes of Burke and Hare were committed in Edinburgh in 1827 and subsequent years. A number of persons were inveigled to Hare's lodgings, where they were murdered and their bodies sold to the college authorities for dissecting purposes. At length suspicion was aroused and the criminals detected. Hare turned King's evidence, and Burke, who also made a full confession, was hanged. Professor Knox, the anatomist who purchased some of the bodies, incurred great public odium. He lost his practice and his pupils and finally left Edinburgh. Shortly after the conviction of Burke and Hare the Anatomy Acts were passed.

Dr. Clarence.—The cause of death being obviously obscure, it would have been more satisfactory if the inquiry had been adjourned for the purpose of having an analysis made of the contents of the stomach.

Experte Credo.—We know of nothing likely to suit our correspondent's requirements.

STRANGE EPITAPH IN MORETON MARSH CHURCH-YARD.

Here lie the bones of Richard Lawton,
Whose death, alas! was strangely brought on;
Trying one day his corns to mow off,
The razor slipped and cut his toe off.
His toe, or rather what it grew to,
An inflammation quickly flew to,
Which took, alas! to mortifying,
And was the cause of Richard's dying.

G. C. L. S.—We are unable to discover the exact bearing of your question. You had better state your requirements in plain terms. and if, at the same time, you will give a postal address you shall receive a private communication.

M. B.—The schedule has not yet been completed, and we cannot at present assign a probable date for its publication.

A DISCLAIMER.

To the Editor of The Medical Press and Circular.

Sir,—The *British Medical Journal* published last week a shor note by me on the use of paraffin for restoring the bridge of the nose. Some of the daily papers have made "copy" of it, and have named me as though I had invented the method. I wish to say that I had nothing whatever to do with the matter, and I wish it could have been prevented.

I am, Sir, yours truly,
Stephen Paget.

September 15th, 1902.

Ergo.—The idea strikes one as preposterous. You had better direct your attention to the elements of the science before launching forth into such hazardous speculations.

Appointments.

Dwyer, Hubert de Burgh, M.R.C.S.Eng., L.R.C.P.Lond., Medical Officer to the Banbury Union Workhouse Infirmary.

Eaton Oliver, L.R.C.P., M R.C.S., D.P.H.Cantab., Public Vaccinator for Exmouth (Devon).

Garland, Edward Charles, M.R.C.S., L.R.C.P.Edin., L.S.A., Medical Officer of Health for Yeovil.

Gibbs, Norman Edward, L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasg., House Surgeon to the West Kent General Hospital.

Kirby, Samuel J. J., M.D.Brussels, Medical Officer of Health of the Hoxne Rural District.

Macfie, Ronald Campbell, M.B., C.M.Aberd., Medical Superintendent of Dundee Sanatorium.

Morrissey, Martin R., L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory Act for the Ballymore Eustace District of the county of Kildare.

Murphy, W. E. Cavanagh, M.B., B.Ch.Dubl., Medical Officer of Health for the Llantarnano (Mon.) Urban District Council.

O'Hagan, Patrick F., L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory Act for the Croydon District of Surrey.

Peacock, Pryce, M.B.Brussels, Certifying Surgeon under the Factory Act for the Castleknock District of the county of Dublin.

Sequeira, James H., M.D.Lond., M.R.C.P.Lond., F.R.C.S.Eng., Assistant Physician to the Skin Department of the London Hospital.

Sharp, Edgar Wm., M.B., Ch.B.Glasg., Resident Medical Officer to the Halifax Workhouse Infirmary.

Vacancies.

Camberwell House Asylum.—Second Assistant Medical Officer. Salary £150 per annum, with board, rooms, and laundry. Applications to the Medical Superintendent, 33, Peckham Road, S.E.

Cornwall County Asylum, Bodmin.—Junior Assistant Medical Officer. Salary £130, with board, furnished apartments, laundry, &c. Applications to the Medical Superintendent.

County Asylum, Rainhill, near Liverpool.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent

Glenties Union.—Medical Officer. Salary £100 per annum. Applications to Michael M'Nelis, Clerk of Union. (See advt.)

Kinsale Union.—Trained Nurse. Salary £45 per annum and rations. Applications to John Murphy, Clerk of Union. (See advt.)

Roxburgh District Asylum, Melrose, N.B.—Assistant Medical Officer. Salary £140 per annum, with board, rooms, and washing. Applications to the Medical Superintendent.

St. Thomas's Hospital and Medical School.—Assistant Pathologist and Demonstrator of Pathology. Salary £250 per annum. Applications to the Treasurer's Clerk.

Withington Urban District Council.—Hospital for Infectious Diseases.—Resident Medical Officer for the Baguley Sanatorium. Salary £120 per annum, with board, apartments, washing, and attendance. Applications to Albert Roberts, Clerk, Town Hall, West Didsbury.

Wonford House Hospital for the Insane, Exeter.—Assistant Medical Officer. Salary £150 per annum, with full board, &c. Applications immediately to the Medical Superintendent.

York Dispensary.—Resident Medical Officer. Salary £110 a year, with board, lodging, and attendance. Applications to W. Draper, Esq., De Grey House, York.

Births.

Collins.—On Sept. 11, at the Red House, Sawbridgeworth, Herts, the wife of Ethelbert Collins, M.R.C.S., L.R.C.P., of a son.

Smith.—On Sept. 6th, at Earl's Court Road, South Kensington, the wife of P. Montague Smith, M.R.C.S.Eng., L.R.C.P.Lond., of a son.

Marriages.

Barry—De Courcy-Ireland.—On Sept. 9th, at Christ Church, Ealing, W., by the Right Rev. Alfred Barry, D.D., Assistant Bishop of London, Captain Cecil Stuart Barry, I.M.S., to Dorothea Alice Maud, second daughter of the late W. de Courcy-Ireland.

Foster—Viret.—On Sept. 10th, at All Saints' Church, Finchley Road, N.W., Albert Ernest Foster, M.R.C.S., L.S.A., of Bradford., to Gertrude Caroline, only daughter of the late Benjamin Pope Viret, of the War Office, London.

Relph—Inman.—On Sept. 10th, at St. Mary's Church, Kilburn, Herbert John Relph, L.D.S., M.R.C.S., L.R.C.P.Lond., of 24, Wimpole Street, London, second son of John B. Relph, of "Ethandene," Hampstead, to Norah, third daughter of the late R. J. Inman, and of Mrs. Inman, "Wulfrana," Greencroft Gardens, West Hampstead.

Deaths.

King-Sampson.—On Sept. 10th, at his residence, Abbotsfield, Lordswood, near Southampton, James King-Sampson, F.R.C.S., aged 86.

Pomery.—On Sept. 2nd, at Bitterne, Southampton, James Robert Moriarty Pomery, M.R.C.S., aged 76.

Paris Clinical Lectures.

TRAUMATIC SCARLATINA.

By DR. R. DE BOVIS,

Professor at the School of Medicine of Rheims.

TRAUMATIC scarlatina is an eruptive, contagious and often epidemic affection which, in the opinion of the majority of those who have studied it, is of the same nature as medical or ordinary scarlatina. Without touching on certain clinical peculiarities, one of its characteristics is that it develops after a traumatism, and, owing to its being frequently of surgical origin, is still known by the name of surgical scalratina.

The English authors were the first, forty years ago, to point out the existence of scarlatiniform eruptions in subjects who had been operated upon or wounded.

The history of surgical scarlatina commences with the works of Sir James Paget and G. May in 1864. Thirteen years later Sir James Paget republished his former notes in his "Clinical Lectures and Essays" of 1877, and in this latter work he stated that he had met with ten cases of surgical scarlatina. Howard Marsh and Thomas Smith mentioned, one eight and the other seven, new cases collected from a total of forty-eight cases of lithotomy in children.

Then, in 1868 and 1870, appeared the works of Verneuil and of his pupil Tremblay, which must have had considerable influence over the evolution of ideas in respect of surgical scarlatina.

Be this as it may, until 1877 the prevailing opinion was that of Sir J. Paget, who recognised the scarlatiniform nature of the majority of these exanthemata. This opinion was shared, and even emphasised, by Trélat and by Batut, who affirmed that surgical scarlatina and ordinary scarlatina were absolutely identical; the English authors, on the contrary, noted certain clinical or epidemiological differences between them.

The articles of Verneuil and of Tremblay, and the accidents attending the use of carbolic acid, ought to have suggested certain reservations. These were noted in a work by Terrillon, concerning a case of scarlatiniform eruption which the author attributed to septicæmia.

During this time, the study of surgical scarlatina was being pursued in England. In the "Guy's Hospital Reports" of 1879, Goodhart and Howse discussed the question in the light of further observations. Goodhart recorded twenty-five cases and Howse three. The notes are, unfortunately, very brief. The same must be said of those brought before the International Medical Congress at London, where the majority of the preceding English authors, as well as Trélat and Riedinger, joined in the discussion. The latter declared that he had observed fifteen cases of surgical scarlatina, including nine already published, but in a very summary form.

Everyone seemed unanimous in admitting the existenceand the frequency of surgical scarlatina, and in regarding it as a new complication of wounds. Yet, in the very year that Riedinger published his first work, Treub challenged the opinions expressed by this author, and even went so far as to affirm that wounds created a certain immunity in respect of scarlatina.

With the works of Hoffa, published in 1887, we enter a period of criticism and revision of prevailing ideas. The principle of a chirurgical scarlatina was always respected, but each author severely criticises all the works that had preceded his own. Hoffa was of opinion that there were four kinds of eruptions: eruptions of vasomotor origin, toxic eruptions, infectious eruptions, and scarlatina itself. To the first group belong the erythemata; to the second, eruptions following on transfusion, the use of sublimate, of belladonna, &c.; to the third, the eruptions of septicæmia, diphtheria, typhoid fever, &c. The number of cases of genuine surgical scarlatina was thus very much reduced, and the author only admitted six or seven as authentic.

Additional observations have since been published in an important work issued ten years ago by Emil Koch, who made a conscientious study of the scarlatiniform eruptions occurring in wounded or tracheotomised children. In 1895, Conrad Brunner brought together nineteen observations, and traced the clinical picture of this "Eogenannten Wundscharlachs." During this time, Volkovitch, Sarytchev, and Nossovitch published or criticised similar cases in Russia.

We are thus confronted by a very much debated question. To prepare the way, we will first of all sketch the picture of surgical scarlatina, as described in the recorded cases, and we will then discuss the pathogenic or diagnostic problems which are connected with it.

In order to elucidate the etiology of chirurgical scarlatina I have collected nearly 150 observations published under this head (excluding certain series of cases published without the least detail). Of these, for various reasons, of which the principal is the insufficiency of clinical details, we can only make use of about a hundred for our purpose.

The preceding figures seem, in any case, to indicate a certain frequency. It is worth noting that the majority of observations belong to the commencement of the antiseptic period, or even to the end of the pre-antiseptic period; at the present day, traumatic scarlatina seems to be of rarer occurrence. It has often taken on an epidemic aspect, notably in children's hospitals, in which certain authors have collected a very considerable number. Goodhart mentions twenty-five cases and Koch thirty-one.

As a matter of fact, it is in the young that traumatic scarlatina is most frequently met with; out of 147 observations, there were 117 concerning subjects under fifteen years of age—a percentage of nearly 80 per cent. Two-thirds were in males, who are always most susceptible in regard to traumatisms.

No particular traumatism can be accused of specially favouring the evolution of surgical scarlatina; some are antiseptic, or supposed to be, as, for example, operations performed on non-infected patients; others are wounds, or superficial cutaneous lesions, of no apparent gravity; in other cases patients already infected were attacked (incision of an ordinary or tuberculous abscess, scraping of glands, tapping, osteotomy and resection of suppurating osseous lesions, simple or tuberculous); others have a kind of mixed character from an antiseptic point of view; the operation for hare-lip, extirpation of lingual papilloma, &c.; lastly, others are antiseptic by definition, such as inoculation with vaccine.

The preceding classification only refers, so to speak, to common infections; but some of a less common type are occasionally met with. Thus a patient of Schäffer's had tetanus; another, recorded by Espine and Marignac, suffered from a slight form of hospital gangrene; a third, whose case was related by Patin, had erysipelas; while E. Koch brought forward a whole series of cases of scarlatina in young tracheotomised diphtheritic subjects.

Contagion by an anterior scarlatina, either medical or surgical, was noted in eighty-five cases out of 150—*i.e.* in 56 per cent. In a number of cases the contagion was not open to doubt. Haffter, for example, relates a case of scarlatina which occurred in a schoolboy who had been scratched by one of his schoolfellows who was actually desquamating. Leube contracted scarlatina by pricking his finger during the post-mortem examination of a scarlatinal subject. A student, operated on for phimosis by Browne, had previously visited a fellow-student suffering from scarlatina. Nossovitch published two cases in which the contagion was less certain, but where the origin of the scarlatina was curious enough to deserve mention: a lady, who was a specialist in piercing ears for earrings, had pierced the ears of two little girls; a few days later these children presented the typical symptoms of scarlatina just at a time when an eruptive fever was epidemic in the village, which may quite possibly have been scarlatina. We must, moreover, bear in mind that, in certain cases, it is the operator who appears to have conveyed the infection. Lastly, in a very large number of observations, contagion appears admissible *a priori*, since they bear on patients in hospital.

To complete these etiological data, bear in mind that Brunner's patient had already had scarlatina. H. Page's patient had even had it twice.

The evolution of surgical scarlatina, like that of medical scarlatina, may be divided into four periods: incubation, invasion, eruption, desquamation.

With regard to the period of incubation it would seem, from the majority of observations, that the infection may occur either during or after traumatism, anterior infection, though quite possible, being the exception, if we bear in mind the absence of any cases confirming its occurrence. In 104 cases of surgical scarlatina the interval between the traumatism and the eruption was, in fifty-seven cases, less than three days; in twenty cases from three to eight days; in eight cases from eight to fifteen days; in two cases from twenty-one to twenty-eight days; lastly, in thirteen cases it was upwards of four weeks. The fact of the progressive decrease of the intervals seems to show, by itself, that infection takes place at a period contemporary with the traumatism.

Since the incubation period of ordinary scarlatina is at the least from three to four days, it is quite possible that several of the cases just mentioned are merely instances of scarlatina in a wounded patient. We can, it is true, as we shall show later, formulate a hypothesis in favour of their being really examples of surgical scarlatina; but we cannot take them into account in determining the duration of the period of incubation. Veit, Hagenbach-Burckhardt, and Gerhart do, as a matter of fact, mention incubations of twelve, fourteen and sixteen days, but these are very rare cases and there are too many exceptions. If, therefore, we restrict our attention to cases in which the traumatism does not date from more than eight days, we find seventy-seven cases with a maximum incubation period (calculated from the date of traumatism of two and a-half days).

The symptoms of the period of invasion are those of every pyrexial infection—a temperature of 39° to 40° or 41° C., shivering, insomnia, restlessness, delirium; in children, convulsions and ordinary gastro-intestinal reactions (vomiting, intense thirst, furred tongue, constipation, or diarrhœa), and especially sore throat. This is the clinical manifestation which ought to interest us most, for it is one of the fundamental symptoms of scarlatina.

In the period of eruption, the first thing to consider is the exanthem. The date of its appearance is rather variable. It may be noted in the night of the day during which the first symptoms of the disease appeared, but, as a general rule, it only appears the following day, or even the day after that; it appeared in forty cases in twenty-four hours; in ten cases in two days; in seven cases in three days; in one case after four days.

This exanthem is often mentioned without details, or is described as "typical," "scarlatiniform," &c., which, in view of the diagnosis, justifies the supposition that it had the usual characteristics of a scarlatinal eruption in respect of starting point, distribution, progression, &c. But this is not always the case.

In twenty-nine cases the eruption was said to emanate from the wound; the latter being surrounded, at first, by a red zone, which raises a suspicion of impending erysipelas: from this red ring start red bands of variable width, reminding one, at times, of lymphangitis, and these grow larger, coalesce, and end by invading the other parts of the body. If the wound is on the face or arms, the thorax is rapidly invaded; if it is on the legs it is the abdomen and upper part of the thighs which present the most pronounced scarlet tint. In any case, it extends very rapidly, and in twenty-four or forty-eight hours the rash appears to have reached its maximum. Its diffusion and distribution seem to be the same as in scarlatina.

This connection between the wound and the eruption is, however, not the rule, since the majority of observers either remark the absence of redness, exanthem or eruptive manifestation around the wound or simply say nothing about it.

As in scarlatina the exanthem may be complicated by the appearance of a miliary eruption. The blisters observed by Bollice in the neighbourhood of the wound are a more abnormal manifestation, and may be simply the result of local infection. Gimmel and Konetschke mention, moreover, a certain œdema of the skin or of the lower extremities, without accompanying albuminuria.

Itching seems to have been as rare as in ordinary scarlatina, since it has only been met with on three occasions.

In a case of Brown's, the eruption did not appear until after death; the evolution had been exceedingly rapid, the patient having died in fifteen hours. The fever, which may reach and even exceed 40° C., progressively decreases when the eruption begins to fade. It is only maintained for two or three days at its maximum, and at the end of five or six days it has altogether subsided.

The sore throat, or, speaking more generally, the tonsillar symptoms, were only absent in ten cases, and these are presumably the only cases where such was the case, for observers could not possibly term "typical" or "characteristic" any scarlatina in which such an important symptom was absent.

The tonsillar manifestations of typical scarlatina present, as is well known, two variations—angina and exanthem. The first, which is of variable intensity, may be absent, although but rarely so; the second is pretty constant. Unfortunately, too many observations are wanting in the minute details which are necessary to enable me to formulate a classification of this kind in respect of traumatic scarlatina. One thing, however, appears certain, viz., that this symptom is less frequent and less severe than in medical scarlatina, since rarely has anything but slight angina, or even simple redness, been observed. Sub-maxillary adenitis, slight exudations or white spots, and *a fortiori*, diphtheroid and diphtheritic exudations, are but rarely referred to.

With reference to the tongue, various authors, especially the English, mention the presence of a thick fur, and the redness of its edges (strawberry tongue), or content themselves with describing it as "scarlatinal," which no doubt includes the preceding characteristics.

A point which has been rather neglected, but one which might be instructive from a diagnostic point of view, is that of the modifications undergone by the wound during surgical scarlatina. A fairly typical observation has been recorded by

Beaudouin; the patient being a child, æt. 4, who had just been circumcised by a doctor who was at the time attending scarlatinal patients. Thirty-six hours after the operation a scarlatiniform eruption started from the wound, the affection ran its course without sore throat, but the wound of the prepuce and glans became covered with "a thick, greyish, pultaceous deposit, identical in appearance with that of diphtheria." The case was so clear that Beaudouin immediately associated this exudative with that observed on the tonsils in ordinary scarlatina. Let us add that the little patient communicated the scarlatina to his doctor, who had not had it previously. I cannot recall any other observations mentioning with such clearness the peculiarity in question, but there are a few cases which deserve notice. Browne had occasion to circumcise a student, who visited, daily, one of his fellow-students suffering from scarlatina; thirty hours after the operation marked scarlatinal symptoms supervened; ten hours later the wound took on a gangrenous aspect, followed by coma and death in seventy hours. Sore throat was absent in this patient, who was, nevertheless, the starting point of a series of surgical scarlatinas.

In the same category may be classed an observation by Howse, who speaks of the "dirty" aspect of the wound and its tendency "to exfoliate in flocculent masses." Other authors refer merely to the earthy appearance of the wound, the swollen and patulous borders with secondary suppuration, the subsequent formation of a slough, slow convalescence, &c.

The various characteristics just mentioned have probably no specific value; since the works of Verneuil and Dunoyer, it has been well known that pyrexia has, generally, a harmful or retarding influence on the healing of wounds. Thus Parker only confirms a general pathological law when he says that during surgical scarlatina "wounds reopen, even when partially healed." This law, however, has exceptions, for, in four cases, the cicatrisation of the wound proceeded without hindrance or delay; but we must bear in mind that in two of them the lesions were very trivial.

The period of desquamation is somewhat variable, commencing generally about the sixth or seventh day following the appearance of the exanthem, rarely later; in a case of Hall's on the ninth day; on the nineteenth day, in a patient of Howse's. First of all, there is a scaliness or dustiness, notably on the face, then the scales grow larger, and we soon notice the appearance on the limbs, around the wound (Leube, Strubell), or in its neighbourhood, of the large characteristic scarlatinal scales. When the desquamation is more abundant around the wound it is because the exanthem originated in that spot. In four cases it remained simply branny. Its absence is only once mentioned: the affection had, nevertheless, been of a rather serious nature, and had been transmitted by contagion to another person. The duration of this period of desquamation, which authors do not as a rule definitely state, was in two cases eight days, in three cases fifteen days, in one case three weeks, in one case forty days.

Among the complications, diphtheria and albuminuria are those which interest us most in respect of the relationship between surgical and ordinary scarlatina. Diphtheria, as we have already shown in connection with sore throat, was only met with in two cases, one of which proved fatal. Albuminuria occurs oftener, and is mentioned in sixteen cases. In two of Koch's patients there appeared, during defervescence or convalescence, a recurrent erysipelas, which started from the wound.

The prognosis, except in subjects tracheotomised for diphtheria and those suffering from a grave surgical affection, is not of great severity, since out of a total of 125 cases, only nine deaths are mentioned. The causes of death are diphtheria, renal or pulmonary complications, and subacute or acute sepsis.

Lastly, we must mention two cases of recurrence of the exanthem, one of which belongs to Konetschke and the other to Schäffer. In the first it was the case of a child with a complicated fracture of the arm, in whom, fourteen days after the accident and a first eruption, followed by desquamation, there appeared a second, paler, eruption, accompanied by fever and fresh desquamation; the same thing recurred eight days later. There were thus three attacks in three weeks, which is certainly extraordinary. Schäffer's patient was attacked by tetanus, which appeared a week after a wound in the finger; nineteen days after the appearance of the tetanus there appeared a scarlatiniform eruption; sixteen days later, when the desquamation had almost ceased, a fresh eruption appeared, having the characteristics and an evolution similar to the first. We have, moreover, mentioned, in connection with etiology, two patients (H. Page, C. Brunner) who were undergoing, one his third, the other his second, attack of scarlatina, but the attacks had not followed each other immediately as in the preceding cases.

It is interesting to note that some of these patients were, to all appearances, the causes of fresh cases of scarlatina by contagion. We have notes of thirteen cases of the kind. Independently of these cases, there are several others in which contagion seems very probable; for example, the series of Murray, Goodhart, Koch, Treub, a total of fifty-one cases which were discovered, generally in epidemic form, in the surgical wards of children's hospitals.

(To be continued.)

Original Communications.

SOME POINTS IN

THE MODERN DIAGNOSIS AND TREATMENT OF ANÆMIAS.

By DAVID WALSH, M.D., C.M.Edin.,

Hon. Physician, Western Skin Hospital.

As a symptom, anæmia demands the careful attention of all who are called upon to undertake the treatment of disease, whether from a general or a special point of view. In our present state of knowledge we are often obliged to confess ourselves baffled in the search for the primary cause of this trouble. In a certain sense all anæmias are secondary to some cause that may either lie on the surface or, on the other hand, be altogether obscure. For purposes of classification, however, it is convenient to divide anæmias into two groups—(*a*) primary, and (*b*) secondary. Of these the primary include the varieties described as idiopathic, pernicious, essential, progressive, and malignant, all of them denoting types that resist treatment, and steadily progress towards a fatal termination. The secondary, or symptomatic, anæmias, on the other hand, run a milder course, and usually follow some ascertainable lesion or injury, or attend some concomitant disease.

Treatment is mainly concerned with the secondary group. Hitherto the great strides that have been made in the knowledge of the facts of the primary anæmias, as often happens in dealing with complex pathological problems, have not been followed by corresponding advances in practical treatment. The therapeutic resources of the physician remain much the same as they were before the development of that most brilliant branch of modern research, the study of the blood changes in disease. There can be little doubt that one day the growing mass of detailed observations will be reduced to general deductions, and the physician will be then enabled either to prevent or to alleviate those abnormal blood conditions that he is now only in too many cases powerless to relieve. In the meantime the most skilful physicians have not been able to devise curative methods to meet the conditions revealed by the blood examinations of the graver anæmias. Nevertheless, the general practitioner will find himself often dependent upon detailed examinations of the blood, both in arriving at diagnosis and in gauging the result of treatment. At the same time, he will not be able to throw aside his former method of clinical observation and of treatment that is more or less empirical. The present state of affairs has been well expressed by Whitla (a) who writes: "Great advance has recently been made in the classification of the different forms of anæmia by the brilliant researches of Ehrlich, Lorrain Smith, and many others. Though these have not yet very rationally helped the therapeutist, it seems certain that we are within a measurable distance of hoping for new aids to the treatment of such diseases as pernicious anæmia and the various forms of leukæmia."

Modern treatment has laid much stress on the value of sunlight, fresh air and exercise in the treatment of the secondary anæmias. Good food is no less essential, especially in the large and sometimes only partially recognised class of starvation anæmias. As regards the latter point, it is interesting to speculate how much of the benefit may be due to the iron which enters the system in organic combination, as in milk, the yolk of eggs, and in certain vegetable and animal albuminoid forms. Exercise doubtless helps matters by stimulating the activity of the excretory organs, notably the skin, whereby the toxic substances that are associated with many anæmias are removed from the circulation. Attention to the state of the alimentary canal also becomes a point of prime importance to the practitioner. The care of the teeth is also essential, and the removal of all dental tissue showing cario-necrotic changes constitutes an early step in routine treatment. Another important point is a clean tongue, which may be regarded as an essential to the success of general measures. Catarrh of the stomach requires careful treatment with such remedies as bismuth and hydrochloric acid, while dyspepsia should be remedied with pepsin and other drugs, combined with a careful attention to diet. Purgatives take an important place, possibly or probably by removing toxic matter from the intestines, as well as by stimulating the excretory functions of the bowel. Speaking on this point Mitchell Bruce (b) writes: "It is of the first importance that the practitioner should appreciate the clinical relations of constipation, not only that he may attach due importance to the treatment of the disorder, but also lest he should be tempted to treat what are but its symptoms, particularly anæmia, as substantive or primary affections instead of through the bowel. In other words, these phenomena have to be referred to the pathological condition of which they are significant, and it, not they, must then be attacked."

The general principles of the treatment of the curable anæmias may be expressed as follows:—

1. To restore tone to the system.
2. To remove toxic substances from the body.
3. To make good deficiencies in the blood.

1. *To Restore Tone to the System.*—This is to be hoped for mainly by placing the patient as far as possible under the conditions essential to a wholesome environment. The latter includes open-air exercise, liberal diet, and so on. Of late much attention has been paid to the influence of climate upon anæmia. Dr. Oliver has referred the apparent increase of red corpuscles in persons removed to high attitudes to a concentration of plasma, but he has further shown that a similar phenomenon may be obtained at sea level in dry climates, such as Egypt. Under these circumstances it would be preferable to send weak anæmic patients to a warm seaside place.

2. *To Remove Toxic Substances from the Body.*—As already stated, attention to the teeth, with regulation of the stomach and bowels, tends to remove or lessen the production of toxic substances from situations whence they can be readily absorbed into the blood. The stimulation of the excretory functions of the intestine is also at the same time effected. Excretion of toxic substances may also be aimed at by stimulating the action of the lungs, the skin, and the kidneys. In this way exercise and warm baths may be made to play a most important part in the cure of anæmia. The present writer has found the Tallerman superheated air treatment of great value in secondary anæmias, more especially in those associated with a gouty or rheumatic taint. He has seen cases of chlorotic young women improve rapidly under the influence of this method alone. The result may not unreasonably be attributed to the elimination of toxic substances in the profuse sweating that follows exposure of a part of the body to the high temperature of 250° or 300°F. This experience accords with that of Senator, of New York, (a) who has seen good results from sweating where other means failed. The pallid dry skin of anæmia is part of the general defect in functions of all the glands of the body, which is regarded by Professor Clifford Allbutt (b) as characteristic of this class of patients.

3. *To Make Good Deficiencies of the Blood*, which is obviously in some cases to be done most directly by diet.—Unfortunately there are often obstacles in the way of digestion and assimilation. As everyone knows, iron, especially in combination with aperients, sometimes gives brilliant results in chlorosis. In other forms of anæmia, however, it is often useless when given in the ordinary form, such as the tincture ferri perchloridi or Blaud's pill. This fact has naturally led to the trial of other combinations, such as those of iron with organic acids, as lactic, citric, acetic and malic acids. These salts, although more readily digestible and non-constipating, nevertheless often failed no less than the inorganic salts in furnishing the blood with the iron that forms one of its essential constituents. The next step was to cast about for some form of iron in direct combination with the molecule of some organic substance. That material enters into ordinary diet, as already mentioned, in such substances as yolk of egg and milk, and it has been proved experimentally that an animal cannot live upon a diet free from organically-combined iron. Analysis shows that the chief constituent of red blood corpuscles, hæmoglobin, contains 0·34 per cent. of iron in combination, an amount that, however small, is larger than in any other substance. Hæmoglobin is, therefore, promising from a theoretical point of view, and has proved clinically satisfactory in the form of "Hæmatogen," which is a preparation composed mainly of hæmoglobin. How the remedy acts is not exactly clear. It may be as suggested in the *Lancet*, of November 6th, 1898, that the good effects may be ascribed to a species of organotherapy, while at the same time it acts as a nutrient. The latter fact is in accordance with the composition of hæmatogen, the bulk of which consists of albuminous matter. This particular preparation, therefore, may produce its good effect by furnishing iron in an easily assimilable form, and as an aid to nutrition. In any case it is free from the drawbacks of the ordinary iron salts, which are apt to cause gastric irritation, headache, and constipation.

Applying the test of clinical results, the present writer has found hæmatogen of value in various anæmic conditions. It proved especially useful in several anæmic children who were being treated for eczema and ringworm. In one case, a girl, æt. 21, under treatment for lupus of the cheek of fourteen years' duration, the general health improved, and colour returned under the administration of hæmatogen, whereas little benefit had been obtained from prolonged courses of the ordinary iron compounds.

The difficulty of administering iron to children is well recognised. They cannot swallow pills, and they naturally decline such astringent and unpleasant drugs as sulphate of iron and the muriated tincture of iron. Clearly it is often imperative that children should have iron in some form or other. Of modern preparations of that drug hæmatogen certainly seems well calculated to meet the requirements of the case. Besides, it has the great advantage of not causing constipation, which is no less a bugbear of the nursery than of adult life.

The quality of non-astringency makes hæmatogen of value in cases where it is not advisable to use the astringent forms of iron. The constipation which almost invariably attends the use of the sulphate and the muriated tincture of iron is in some cases most undesirable, if not actually dangerous, and has to be counteracted by combination of the iron with purgatives, such as the sulphate of magnesia or aloes. The constant use of aperients, it need hardly be remarked, creates peculiar dangers, among which may be mentioned congestion of the pelvic organs and hæmorrhoids, the latter especially when aloes is the active agent. As the greater amount of the ordinary salts of iron given by the mouth unquestionably goes through the body unaltered, it seems rational to give a mild organic and absorbable iron compound like hæmatogen, with the use of an occasional aperient where necessary, and at the same time to pay careful attention to the whole of the digestive organs.

(b) *Ibid.*, February 10th, 1901.

In very acute and severe cases transfusion of healthy human blood or of sterilised normal saline solution may be required.

Among general drugs in the treatment of anæmia nux vomica is entitled to a high place for various reasons, which may be summed up in the statement that it acts at once as a gastric, vascular, and nervous tonic (Brunton). It is of special value in bracing up the atonic muscular walls of the stomach and intestines. The constipation that is so common a feature in anæmic conditions may be treated with this drug, of which Dr. Phillips writes: "Five to ten drops of the tincture of nux vomica, taken in a tumbler of cold water before breakfast and dinner, acts as a laxative, and often overcomes chronic constipation." (*a*)

Arsenic in small doses is a useful drug in the treatment of anæmia, although the tendency of late years has been to use this drug more and more cautiously; it is an undoubted fact that many cases of chlorosis may be cured rapidly without the administration of arsenic.

There is no need to do more than mention the various preparations of iron that are in everyday use, such as the sulphate, the tincture of the perchloride, Blaud's pill, reduced iron, the citrate of iron and ammonia, and the vinum ferri.

Mercury is often useful in overcoming the constipation, and may be given in a dose of one-third of a grain of calomel, or one grain of grey powder every three hours for twenty-four hours, or a small dose of grey powder may be given nightly for several weeks.

The foregoing points are of the nature of rough notes of one's clinical experience of some of the curable anæmic conditions. In the hope that they may have some suggestive value to others, they have been brought together in this brief and informal article, which will be concluded by a few notes upon the more prominent anæmias.

Apart from the anæmia due to insufficient or improper food, and to hæmorrhage or other drain upon the blood, stands the large group connected with certain specific infections and toxæmic processes; of the former a good instance is afforded by malaria, due to a hæmatozoon that directly attacks the red blood corpuscles. Syphilis is often associated with a marked anæmia. Certain metallic poisons, notably lead, invariably produce anæmia. Many of the infectious fevers cause destruction of blood corpuscles, as in enteric fever and diphtheria. Another group of toxæmias may originate in the intestinal canal, as in the well-known copræmia theory of the late Sir Andrew Clark, which ascribes chlorosis to "auto-intoxication," or the absorption of toxic material from the fæcally obstructed bowel of chronic constipation.

A note may be appended as to a few of the chief features of chlorosis, pernicious anæmia, splenic anæmia, Hodgkin's disease, and leucocythæmia.

Chlorosis is a common and curable malady occurring almost entirely with young women. There is a peculiar greenish pallor of the skin, and symptoms of anæmia of brain, heart, and other organs, such as fainting, dyspnœa, and amenorrhœa, with hæmic cardiac bruits and œdema of extremities. The most marked change in the blood is a relative fall in hæmoglobin. Taking the average of red blood corpuscles as 5,000,000 per cubic mm., with a hæmoglobin standard of 100 per cent., in chlorosis the red corpuscles fall to, say, 3,500,000, while the white corpuscles are unaltered in number. The great change is in the hæmoglobin, which falls to 50 or 60 of the normal. The colour index of the individual corpuscles falls to 0 6 or 0·5 instead of the standard 1. The most generally accepted modern view is that in chlorosis (*a*) "there is a defect in hæmogenosis, whereby the red corpuscles are unable to take up their normal amount of hæmoglobin."

Pernicious Anæmia is a disease chiefly of maturity met with in both sexes. It is progressive in character, and almost invariably fatal. There is feebleness and great pallor of skin, usually of a yellowish or lemon tint, with a marked tendency to hæmorrhages, recurrent febrile attacks, quick pulse, hæmic base murmurs, œdema palpitation, dyspnœa, and other signs and symptoms of anæmia. The changes in the blood are distinctive. The red corpuscles fall from 5,000,000 to about 1,500,000 per cubic mm. The hæmoglobin is about 30 to 50 per cent., but is relatively increased in amount, as shown by the colour index of 1·6, a condition exactly the opposite of that in chlorosis in which the hæmoglobin is relatively decreased, as shown by the colour index 0·7. The white corpuscles fall from 8,500 to 400, and the relation of red to white corpuscles in pernicious anæmia is 1 in 250. The red corpuscles show great variation in size, and giant forms (megalocytes) are constantly present, as well as microcytes, and some nucleated red corpuscles are always present. The red corpuscles show great irregularity of form (poikilocytosis). The spleen is sometimes slightly enlarged, but the enlargement does not form a feature of the malady, as in the following conditions.

Splenic Anæmia in the adult is a profound and progressive anæmia, associated with an enlarged spleen, but without leucocytosis or enlarged glands. There is a considerable fall in red corpuscles, 3,000,000 to the cubic mm. The hæmoglobin is greatly reduced (from 100 to 30). The white corpuscles sink from 8,500 to 6,000, with a relative proportion to red corpuscles of about 1 in 500. Splenic anæmia is sharply separated from Hodgkin's disease and from leukæmia by the leucocytosis in these two conditions.

Leukæmia, or Leucocythæmia, is characterised by a large increase of white cells and enlargement of the spleen. There are two chief types: 1, the splenomedullary; and, 2, the lymphatic.

1. The spleno-medullary, in which the changes are chiefly in the spleen and in the bone marrow, and the blood shows a great increase in large mononuclear cells (myelocytes), supposed to be derived from the latter, and not present in normal blood. The red corpuscles fall from 5,000 000 to 3,000,000 per cubic mm., but the white corpuscles mount from 8,500 to 500,000, and show a proportion of 1 to 4 red corpuscles, or sometimes even less.

2. In the lymphatic form there is enlargement of lymphatic glands. The red corpuscles fall to 2,500,000, but the leucocytosis is far less marked than in the first variety, namely, 125,000 per cubic mm. The white cells are mainly large and small hyaline mononuclear leucocytes. The proportion of white to red corpuscles is about 1 to 20.

From the foregoing notes it will be seen that both diagnosis and prognosis may often be determined by examination of the blood. The pathological increase of white cells after severe hæmorrhage, and in toxic and inflammatory conditions, can also be distinguished by the nature of the cells.

The Danish Government means to maintain a foremost place in the application of the best findings of medical science. A new Serum Institute was recently opened at Copenhagen, and at the inauguration this country was represented by Dr. Dean, of the Jenner Institute, and Professor Sims Woodhead, of Cambridge.

SOME ASPECTS OF MODERN SEWAGE DISPOSAL.

By ROBERT CALDWELL, F.R.C.S., D.P.H.,
Major, Royal Army Medical Corps.

Science teaches that matter is indestructible, and that the varying manifestations of life are dependent on a constant rearrangement, by natural forces, of atoms whose properties must for ever remain unchanged and unchangeable. The nitrogen which enters into the composition of vegetable albumin, on being taken as food by man or other animal, is passed through the alimentary canal either in its original form or else as part of some other complex chemical substance; or, more probably, it leaves the body by the urinary tract in the form of urea or some compound of a like nature. Whatever form it may take as an excretion, its fate, when returned to the soil, will be, in all cases, the same. The complex organic body of which it forms part is resolved into its primary constituents, and these forming food for plant life, once again become part of that albumin from which the cycle started. Assimilation by the animal body, instead of excretion, would make no change in its destination, animal forms after death being subjected to exactly the same influences as other organic matter, all returning alike to those ultimate forms out of which they first arose. The atoms of carbon, and hydrogen, and O entering into the formation of fats and carbo hydrates, traverse the same circle as those of nitrogen, the transformation which they undergo being, broadly speaking, of a similar nature.

The whole matter may be briefly restated as follows: Simple inorganic forms being absorbed as food by plants are changed into such organic compounds as starch, fat, albumin and sugar, and these, serving first as food for the animal world, are, after varying physiological changes, upon which the process of animal nutrition depends, returned to the soil as urea, uric acid, leucin, tyrosin, &c., and ultimately resolved into their inorganic constituents. It is in this last form that they constitute the food necessary for the maintenance of vegetable life. The products of respiration mainly exist as inorganic forms, and therefore available for plant life without the intervention of soil influence.

It is perfectly clear that if one link in this chain is broken the whole circle must fall to pieces and life such as we know it must cease to exist. This fact is well known, but its practical application does not at all times meet with that recognition which its vast importance deserves. The biological treatment of sewage so largely in vogue at the present day may fairly be taken as an illustration of the truth of the above statement. In this system of sewage disposal the organic matter to be treated is led on to a filter bed of coke, coal, clinker, or like material, and then subjected to the same bacterial agencies as those normally resident in the soil, and which result in the transformation of organic into inorganic matter. The process is, therefore, an imitation of what daily takes place in nature, with the important exception of the fact that in the latter case the inorganic forms which constitute the final result of bacterial activity are utilised for the maintenance of the surrounding vegetation, and indirectly of those animal forms which depend upon it for the continuance of their existence. In the case of the artificial process, what is known as the final effluent is discharged into the nearest convenient watercourse, its main effect, if in the neighbourhood of the sea, being to spread disease by the medium of oysters and other forms of shellfish.

It should be fully borne in mind that the changes which result in the transformation in the soil of organic into inorganic matter, being putrefactive in their nature, are brought about by the influence of micro-organisms; the older systems of sewage disposal, in which the crude material was applied directly to the soil, failed, most probably, in virtue of the fact that the available land was insufficient in extent for the purpose to which it was applied, the soil organisms being unable, in consequence to complete the task demanded of them.

Sewage, of course, must be got rid of somehow, but once reduced to simple inorganic forms it ceases to be sewage (properly so-called) but should be considered as a fertilising agent, absolutely essential for the continuance of life, and provided for us by the laws of nature. This reduction is admirably effected by the biological processes in question, after which all nuisance is at an end, and what was lately putrefying matter is now an odourless liquid of high manurial value, which, according to our present ideas, is diverted from its natural destination, *i.e.*, the soil, to an artificial destination, where its effect can only be for evil.

Quoting from Parke's and Kenwood's "Hygiene and Public Health," the following may be considered as a fair sewage effluent after biological treatment:—

		Parts per 100,000.
Saline and free ammonia		1·50
Organic ammonia		·15
Oxygen absorbed in four hours at 80° F.		1·50
Oxidised nitrogen		1·20
Chloric		10·50
Suspended matter		2·15
Solids in solution		86·15
(*a*) Volatile	35·05	
(*b*) Non-Volatile	51·10	

Supposing such a high standard of purity as that indicated above is maintained throughout the United Kingdom these figures will give some approximate idea of the waste which daily goes on in our midst. It is perfectly true that the application of effluents to land after biological treatment, as directed by the Local Government Board, has not proved an unqualified success, but the failure may be attributed to the fact that the land obtainable is of insufficient area, and therefore rapidly becomes waterlogged. And this point opens up the wide question (one upon which the lives and well-being of thousands depends) as to how far the views of private landowners are to stand in the way of progressive legislation.

There is another aspect to this question, also of the gravest importance. Investigations carried out by the most eminent sanitarians of the day point to the fact that the biological treatment of sewage is no guarantee of the destruction of pathogenic organisms. Dr. Houston, in connection with a recent Commission on Sewage, speaks as follows:—"That it is doubtful if any bacterial process in practical operation at the present time 'treats' or 'detains' the sewage for a sufficiently long period to allow of the complete destruction of all the pathogenic germs by bacterial agencies" (*B. M. J.*, Vol. II., August 18th, 1900). Professor Glasiter, in a paper on "Sewage Disposal and Sewage Purification," read before the Philosophical Society of Glasgow on March 20th, 1901, states, as regarding the same question, "We may legitimately infer—although it is but mere inference—that the enteric fever and cholera bacilli will also survive the treatment and pass by the effluents." On the other hand, according to the Report of the Medical Officer of the Local Government Board for 1900 and 1901, the investigations of Dr. Sidney Martin, F.R.S., most forcibly indicate that the enteric bacillus dies out rapidly in unsterilised cultivated soils. The practical inference of Dr. Martin's admirable work is, of course, sufficiently obvious, and it is sincerely to be trusted that beneficial results are not far distant. There are, indeed, at present indications that the public mind is awakening to the dangers and disadvantages of the present system, and in this connection it is satisfactory to learn that Lord Iddesleigh in his address to the recent Congress of the Royal Institute of Public Health at Exeter, stated that the question of the application of sewage to land was receiving the attention of the Royal Commission of which he is President.

Even if the necessary information were available, it would be obviously impossible to discuss within the limits of a short communication a question involving the most complex considerations, not only of a scientific, but also of an economic and political nature. An effort therefore has only been made here to arouse interest by treating the question in a general sense, and the time for this attempt should not be unpropitious in view of the Royal Commission on Sewage Disposal, which is now sitting.

THE MENTAL FACTOR IN MEDICINE. *(a)*

By ALFRED T. SCHOFIELD, M.D.

Last year I read a somewhat similar paper in the Psychological Section, and then found that the mind that was really studied by the medical profession was the pathological or insane mind. This short paper on the sane mind concerns the medical profession generally, and is, therefore, in its right place in this Section.

The subject is important for two reasons—for its use, and its abuse. Two letters on this latter, called "The Borderland of Quackery," have appeared in the *British Medical Journal*, in which a good deal is said against the methods and finance of quackery, and but little against the cures, save in this remarkable sentence: "Quackery may be left to itself to stew in the juice of its hollow pretentions *(sic)*, and ultimately to perish as soon as the credulity of its victims has awakened to the fact that they have been duped." Metaphor and construction are here most obscure, and the meaning, though plain, will not be realised in our day. Quackery has been "stewing in its hollow juice" a long time, but the mess is still palatable to mankind, and will continue so as long as the public think so much of cures —as they do; and that cures are effected—as they are. Quacks have long exploited for their own unscrupulous ends that very force of mind so neglected by the profession, and the time has come when its physiological, pathological and therapeutical action must be seriously considered.

One great difficulty is the limitation of "mind" by English psychologists to "consciousness." This part of the mind has little direct power over the body in health or disease; whereas the subconscious mind has almost unlimited power. To understand the mental factor in medicine, the mind *as a whole* must be accepted, and not merely that part that is visible by consciousness. The mind plays a great part in physiology. The body is a complete whole, and an organic unity. This is greatly obscured of late in *teaching* and *practice* in the schools.

In *teaching*, our physiologies are increasingly scientific, and content with mere descriptions of mechanism, pretty much as a treatise on a motor-car might be written, and thus the true unity of the human being drops out of sight.

In *practice*, specialism is so rampant and the patient so segmented that the doctor who studies man as a whole is hard to find. Every system of the body varies incessantly in its processes according to the central guiding power, and never proceeds in the mechanical way many books suggest.

Passing on to pathology, hardly a man of the first rank exists who has not recorded diseases produced by mind. Those given by Wilks, Grabham-Lys, Clouston, MacKenzie, Sansom, Allbutt, Van Noorden, Murchison, Snow, Clarke, Bennett, and others, include most organic, and even infectious, diseases.

Turning to therapeutics, a ground swarming with quacks of all sorts, it may be well to state that I am no faith healer, Christian scientist, "pathist," or "faddist" of any sort, but take my stand upon legitimate medicine alone, as a plain medical man whose practice in nerve disease has led him to study this subject: and I say that the scientific study of psychotherapy is practically unknown to the profession.

Three disastrous results ensue—(1) the loss of the knowledge, (2) the loss to the patient, (3) the support given to quackery by driving patients to them who might be cured.

The following extract from a letter of Sir J. Paget to Sir H. Ackland makes this plain:—"What unsatisfactory cases these are! This clever, charming, and widely-known lady will some day disgrace us all by being juggled out of her maladies by some bold quack, who by mere force of assertion will give her the will to bear, or forget, or suppress all the turbulences of her nervous system." The picture this presents is amazing. We see these distinguished men calmly awaiting their inevitable disgrace at the hands of some bold quack in the cure of this clever and charming lady, whom they seem powerless to help.

What, then, makes such a picture possible? Can it be that the "bold quack" wields some power called "mere force of assertion," that the physician either does not understand or does not condescend to use? Yet sooner than stand disgraced by bold quacks it would be well if the profession tried it, and more especially when its effects on the patient is regarded so favourably by Sir James Paget.

Psychotherapy is exercised in two ways;—

1. Naturally, without medical aid, by the *vis-medicatrix-naturæ*, and it may be said broadly that no therapeutics avail without its aid, and where this is wholly absent recovery does not take place. The most a doctor can do is to assist the body in making use of this great power, which is nothing more than the action of the subconscious mind.
2. The physician can call forth further energies by the power of his personality, and conscious and unconscious suggestions, both direct and indirect.

The few who use these means do so empirically and distrustfully, as the knowledge has never been acquired scientifically in the schools as it should be.

Time fails to enter into details which could be given, and I conclude.

Gentlemen, the state of things I have described must be altered, and I hope my short appeal may result in action, and that in any case you will overlook the plainness of my words in the importance of my subject.

(a) Abstract of paper in Medical Section of the British Medical Association at Manchester, August, 1902 (not read for want of time).

INFANTILISM AND SENILISM. *(a)*

By HASTINGS GILFORD, F.R.C.S.Eng.,
Reading.

The word *infantilism* has been applied by the French to conditions of generalised delay or arrest of development, and the word *senilism* is applicable to the opposite condition of precocious development. These words are, therefore, to development what dwarfism and giantism are to growth.

Infantilism.

Infantilism, like dwarfism, may be due to natural causes. It is merely a variation of normal development carried to an extreme, and may be termed *normal infantilism*. An instance of this was given in which a girl of 15½ was of the height of a child of 6 years, but showed a sexual development like that which is normal at 12 years.

Morbid Infantilism.—Marked delay of development may be associated with disease of the thyroid gland, pituitary body, sexual organs, and other parts. Infantilism, in fact, like dwarfism, is produced by many causes.

Ateleiosis.—But there is one condition in which it is by far the most marked feature, but for which no cause can be discovered. This form of infantilism has received the name of ateleiosis, from ἀτελείωσις, not arriving at perfection. It may be distinguished by its abrupt onset without perceptible cause; by conspicuous infantilism with retention of the intelligence, and by a special tendency to delay of development of the sexual system. About a dozen cases have been described. The delay of development may be so conspicuous that a man of twenty-eight affected with the disease may resemble a boy of six or seven years, and may have a skeletal development which is usually met with at fourteen. The disease presents a distinct facial type. A typical case was described and shown, together with photographs of five others.

(a) Abstract of Paper read before British Medical Association Meeting, 1902.

Senilism.

Senilism, like infantilism, dwarfism, and giantism, may be merely a preternatural variation of normal development. Instances of this *normal senilism* were given.

Morbid Senilism.—Precocious development is usually associated with premature appearance of the sexual functions, and it may also be due to acromegaly, to mental shock, or to syphilis. Instances of senilism due to the first of these causes were then described, and a short account was given of the celebrated French dwarf Bébé.

Progeria.—After putting on one side cases of normal senilism and those which are the outcome of some known disease, a form of senilism still remains to be accounted for. This disease, which has received the name of progeria (πρόγηρος, premature old age) has certain distinguishing features. The onset is abrupt; it comes on without perceptible cause; gives rise to senilism of a very conspicuous character, and does not affect the intelligence. Only two instances of this disease are known, but they were extraordinarily alike. They strongly resembled each other in height, in form, facial characters, and in nearly every other respect. They died, one at seventeen from angina pectoris, and the other at fifteen from influenza combined with general failure of health and other indications of senile decay. In their later years their emaciated, wizened, bent, and feeble figures, combined with their baldness, their projecting veins and entire absence of elasticity of carriage, caused them to present a caricature, rather than a picture, of old age. Photographs of these and other forms of senilism were shown.

THE PATHOLOGY OF NERVE DEGENERATION. (*a*)

By PURVES STEWART, M.A., M.D.Ed., M.R.C.P.Lond.,

Assistant Physician to the Westminster Hospital.

In the course of his remarks, the author referred to Waller's paper in 1850 and to Ranvier's work in 1873, and followed this by a lantern demonstration illustrating the histology of the processes of nerve degeneration and of regeneration. He pointed out that degenerative changes occurred in the distal segment of a divided nerve whether it was sutured immediately or not. Primary union without degeneration did not take place. The degenerative changes also affected a small part of the proximal segment in the neighbourhood of the wound of division. The cellular changes in degeneration consisted, firstly, in a transient invasion by leucocytes, which was succeeded by connective-tissue-cell proliferation. By the end of five weeks the connective-tissue cells had absorbed all the myelin. The neurilemma cells, meanwhile, proliferated, became spindle-shaped and arranged themselves in longitudinal rows with overlapping protoplasmic processes. Fragmentation of the axis-cylinders and medullary-sheaths began on the fourth day. Regeneration overlapped degeneration in point of time. In the distal segment of a divided nerve, after primary suture, "spider-cells" shot out axis-cylinder processes from their opposite poles at the end of three weeks. These neuroblasts were the neurilemma cells and the overlapping threads fused together into a continuous axon. The new medullary-sheaths were similarly formed from the neurilemma cells. In a reunited nerve five months after reunion the nerve fibres had practically attained to normal dimensions. In the distal segment of a non-united nerve the process was essentially the same, but the new nerve fibres did not attain to maturity. The well-known "end-bulb" on the proximal segment of a divided nerve was formed at the outset by the curling back on themselves of the loose divided ends of the divided nerve fibres, and subsequently there was a deposition of new nerve fibres in it, derived from the neurilemma cells.

The deduction from these facts was that since regeneration occurred in the distal segment of a non-united nerve, the so-called "neurone" theory of Waldeyer could no longer be maintained. Dr. Stewart supported the fibrillar theory of Apathy, according to which the essential elements of the nervous system are the nerve fibrils. The nerve cells merely served as convenient shunts, and the central nervous system was one vast exchange transmitting nerve impulses from one part to another. The central nervous system, however, undoubtedly exercised a profound influence on the peripheral nerves, without which the new nerve fibres in the distal segment did not attain maturity. For the complete regeneration of a nerve fibre, therefore, two factors were necessary:—(1) The presence of neurilemma cells. (2) The re-establishment of conduction of impulses to and from the central nervous system.

Paris, September 20th, 1902.

Cardiac Asthenia.

Professor Lupus has published an able article on the symptoms or stigmates of cardiac asthenia, that is to say, potential insufficiency of the heart. Amongst the most characteristic symptoms he mentions the inclination to yawning, especially in the morning and during the afternoon. The nights are bad, sleep superficial, and the patient rises in the morning tired.

Another sign is the imperfect peripheric nutrition of the body and revealing itself by continual exfoliation of the scalp, pityriasis, and the falling of the hair, of which the bulb, badly nourished, is extracted by the slightest effort, especially in women. Such persons become grey prematurely.

The influence of the heart on the bladder is well known. In asthenic patients there is more or less considerable stagnation of urine in the bladder on account of the low tone of the heart and the weak muscular contractibility of the bladder, but, what is less known, is the more frequent desire to micturate on account of the greater impressionability of the urinary receptacle.

Women suffering from cardiac asthenia frequently complain of pain in the sole of the foot and the heel. They imagine that they have been pricked by nails in their boots and continually examine them, but naturally none are found.

Other striking characteristics are palpitation, weakness in the limbs, especially felt in mounting stairs,

---

(*a*) Abstract of Paper read in the Section of Pathology at the British Medical Association Meeting, August, 1902.

and fear. Children, for instance, suffering from the affection, are great cowards, afraid of darkness, &c.

The treatment should naturally be that of raising the muscular tonus of the heart. Small doses of digitalis, sparteine or convallarine, combined with nitroglycerine, will render good service. Professor Lupus recommends highly for the same purpose iodide, associated with tannin, as found in walnut leaves in the organic state. Consequently, preparations of walnut leaves, either in the form of decoction or extract, if given a prolonged trial. constitute the best treatment of the affection in question, especially in the case of children.

THE *Deutsch M. Z.*, No. 71, has a reference to a paper by Dr. F. de Quervain on

THE ETIOLOGY OF PNEUMOCOCCAL PERITONITIS.

Most authors assume a primary pneumococcal peritonitis, and also a sharply defined symptomatology for it, especially in the case of women and children. This corresponds to the so-called idiopathic form of the disease. The writer adds two new observations to the sixty-two already recorded. The first case was that of a women of forty-nine, who had a large fluctuating abscess in the abdominal walls that made its first appearance a few weeks after an attack of influenza. The abscess was opened and contained only a few pneumococci. In the cicatrix, a few months later, a cylindrical-celled cancer developed. The second case was that of a girl who had symptoms of perityphlitis, and during the attack herpes labialis appeared. There was superficial dulness in the right lower abdominal region. An incision was made into this area of dulness, the subserous tissues were scarcely infiltrated, but the peritoneum was markedly thickened. On opening this about 300 grms. of greyish-white odourless pus escaped. Examination of this revealed numerous pneumococci in short and long chains. Recovery was very tedious. A slight broncho-pneumonia had also developed in the right lower lobe. Some months later a second operation was undertaken, when the vermiform appendix was removed by crushing. This showed a slight degree of infection, but otherwise appeared normal. For about five months after opening the abscess numerous pneumococci were present in the cavity ; its walls, however, were free from these or any other organisms. The writer believes the case was one of pneumococcal appendicitis, the infection probably arising from the interior of the appendix. The pneumococci of the pus killed mice in forty-eight hours with pneumococci in their blood. This was usually the case in such experiments. When they failed to act in this way the cause might be threefold. The varieties might be different from the first, or one might be dealing with a pneumococcus that had lost part of its virulence in the intestinal canal, or, lastly, the diminution in the virulence might be due to the simultaneous development of other intestinal bacteria in the pus.

Although in some cases the pneumococcus was not found in the vermiform appendix, the large proportion of cases in which the symptoms were most pronounced in the right side, or were exclusively located about the ileo-cæcal valve, pointed to the probability of the appendicular origin of pneumococcal peritonitis, most of the cases being characterised by a fairly uniform course. After a very stormy onset, there comes a period in which the focus is encapsuled, to discharge finally at the umbilicus. This depended on the biological characteristics of the pneumococcus. Other perityphlitic abscesses behaved in a similar manner so soon as the virulence of the micro-organisms had subsided.

The writer divides pneumococcal peritonitis into the primary and secondary forms. The infection of the peritoneum takes place through the blood or lymph channels. The following come into consideration as sources of infection :—The upper air and food passages ; the lungs and pleura (shown in fourteen cases), the infection passing *per commentatem* through the diaphragm, the stomach, and intestinal canal (*a*) by means of ulcerated new growths, &c. (four cases, all adults); (*b*) from injury ; (*c*) from the vermiform appendix (probable in eighteen cases) ; the female genital organs (only one probable case known).

Clinically primary form. To this group belong all cases in which no focus can be demonstrated.

The treatment does not differ from that of perityphlitic abscess from other causes, namely, incision of the abscess and subsequent removal of the appendix.

The *Berlin Klin.-Wochensch.* 22-23, 1902, contains an article on the

ALBUMINURIA OF PREGNANCY,

by Professor Veit, of Leyden, from which the following conclusions are drawn :—

By introducing a sufficiently large quantity of placenta into the abdominal cavities of rabbits albuminuria is set up. The pigment of the skin of pregnant women contains iron. The urine of pregnant women contains rather more iron than the urine of non-pregnant women. The blood serum of pregnant women only exceptionally contains hæmoglobin. The blood serum of women in labour contains hæmoglobin rather more frequently. The blood serum of the new-born child contains generally no hæmoglobin, but it has been observed as an exception. The author demands that the obstetric klinik should be furnished with a well-fitted laboratory in which the newer methods of investigation can be carried out as regards chemistry, physics, and physical chemistry. Obstetrics not only strive to deliver the woman in the best possible manner, but also aim at the improvement of our knowledge as regards the influence of pregnancy on the organism. The more the favourable influence of pregnancy on the woman becomes known, the better shall we know how to avoid harmful consequences by the powers of nature, and the better will the well-being of woman be ensured.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, September 20th, 1902.

COMPLEX SYMPTOMS OF BANTI'S DISEASE.

At the "Gesellschaft für Innere Medicin" Weinberger exhibited a patient suffering from symptoms pointing to Banti's case. The patient was 30 years of age, and seven years ago suffered from a severe attack of malaria which lasted four years, and then ceased on his changing his residence to a healthy climate. Later, however, he suffered from a very severe anæmia, which had lasted up to the present time. Two days before his admission into hospital he had had an attack of severe hæmatemesis with black stools.

On examination he found severe anæmia, enlarged spleen, well-marked ascites, liver small but hard, indicating some structural changes. Although his first impression was that the case was hopeless, the patient rapidly improved under arsenic and iron administration, gaining in weight, strength, and vigour under a generous diet. The ascites disappeared, and within two months he was feeling perfectly well. To complete this recovery he went into the country.

On admission the hæmoglobin was 20 per cent., on his departure 55 per cent., while the proportion of leucocytes was reduced.

These complex symptoms have a close resemblance to Banti's case, in so far as the chronic enlargement of the spleen is the primary cause of the anæmia and hæmatemesis with subsequent recovery. In both cases ascites was present, but in this case the interstitial changes of the liver were not so clearly explained, although they quite disappeared. The presumption is that the sudden appearance of the ascites, with the hæmatemesis and its subsequent disappearance, was due to a thrombus in the portal artery which became absorbed. It could hardly be a sclerosis of the artery such as Banti found post mortem, or the speedy recovery would not have been so complete.

Lightning Injury.

Jellinek next showed a man who had been struck by lightning twenty-six days previously, rendering him unconscious for a time. After recovering consciousness he complained of great pain in the back and legs. The hearing, bladder, bowels, and muscles of the legs were affected, and there was tenesmus, with anuria and cramp.

Jellinek saw him on the sixth day after the accident and noted as follows: Dulness of hearing, muscular power in legs almost nil, while the cutaneous appearances were characteristic. At the lower part of the spine, on approaching the nates, was an area about the size of the hand, with irregular edges, a dark brown hard leathery surface, which, when percussed with a rod, scalpel, or pencil, yielded a ringing sound.

Running out from the margin of this brown hard surface were red lines extending to the great trochanter, down the legs and round the buttocks, giving the area a curious red appearance, with here and there a number of small blisters. The hair on the outer side of the leg, as well as the pubis and perineum on the left side, was singed. On account of the severity of the case, he was removed to Schrotter's ward, where he has generally improved both in respect of the cutaneous and nervous symptoms. The lesions are characteristic of the injury caused by natural and artificial electricity. There was no burning of clothes over the part; indeed, they could hardly be said to be singed, although such an extensive burn was to be found on the body, where the current appears to have spent its force at the point of entrance, radiating far and wide under the clothes, singeing the hair and burning the skin.

Prophylaxis of Mercurialis Stomatitis and Proctitis.

Bockhart draws attention to the treatment of mercurial stomatitis by the use of paste or tooth powder which has been effective in the prophylaxis of the disease, as well as the treatment of the disease. Bockhart uses a powder for the teeth which contains 50 per cent. of the chlorate of potass with perfect success. Its efficacy lies in the powerful oxidising property of the chlorate, which speedily acts on all decomposing organic matter. He always prescribes this paste when administering mercury, which entirely prevents salivation in syphilitic patients. In proctitis mercurialis, as well as stomatitis, this prophylaxis is equally efficacious.

Tabes and Mercury.

Bockhart next gave his experience of administering mercury in tabic diseases, which he has practised in the interstitial atactic and initial stages with great success. Instead of the heroic twenty-five or fifty rubbings or inunctions, he prefers to use three to six grammes of the ointment in small quantities extending over twenty to twenty-four inunctions at a time, which might be repeated after a periodical cycle, but not exceeding 2·5 grammes at any of these periods of twenty inunctions. During the treatment warm baths of 25° to 27° Reaumur, or 88° to 94° Fahr., should be taken, but not to extend beyond ten or fifteen minutes at any time, while rubbing should be performed at the same time. The patient should have ten hours' rest in bed at night and two in the afternoon every day. No extraordinary efforts should be made, on the contrary rest, but open air in abundance should be provided. Tobacco and alcohol should be sternly prohibited. This form of treatment should be persevered in for years. He had under his care sixty-nine cases of tabes recently, and in the whole number observed three only who had the slightest symptom of mercurialism; fifty-eight of these came under his care in the initial stage and eleven in the atactic. In fourteen of the cases, or 20 per cent., a perfect cessation of the disease took place, all the tabic symptoms disappearing, even to the patellar reflex and pupillary paralysis; the others were free of pain and felt well.

Although his statistics are yet low on the subject, he thinks this small success warrants a repeated trial of the treatment.

Stypticin.

Kaufmann's stypticin is now gaining favour as a local hæmostatic in case of warts, piles, &c., from which bleeding is often profuse. It is a salt of cotarnin having the formula $C_{12}H_{14}NO_2Cl$. It has been used with success in urologic operations of the bladder, such as endoscopic examination, Oberlander-Kollman operation for dilatation of the urethra, &c., combined with oil cacao, or gelatine, according to the following formulæ:—

R. Stypticini, gramme 0·03 to 0·04,
Olei cacæ „ 1·5 M.

Fiat bacilli urethrales longitudine 10 c.m., crassitudine 4 m.m.

When applied to a bleeding surface after the removal of condylomata or wart, wadding soaked with a solution of 30 per cent. of stypticin is all that is required.

Credeism in the New-born.

Leopold, of Dresden, has attracted attention from his avowal and advocacy of Crede's method of administrating nitrate of silver in a dilute form to the eyes of new-born children to prevent subsequent inflammation

Since 1898 he has practised this method on 2,146 cases, with only three attacks, or 0·14 per cent. of the cases. He formerly used a 2 per cent., but he thinks a 1 per cent. is sufficient for preventing an ordinary case of blennorrhœa.

Pulmonary Phthisis Treated by Cutting the First Costal Cartilage.

Freund startles the surgeon with an announcement that he now cures pulmonary disease by severing the cartilage of the first rib, and allowing the apex of the lung more room to expand, and thus expel by its freedom of expansion and contraction all poisonous matter that may lead to primary destruction of lung tissue. He contends that this stenosis is the cause of bacillary arrests and final destruction, and cites cases where the lung has quite recovered under this treatment of extended aeration, even after the bacillary condition of the lung has set in.

Pyometra in Uterus Bicornis Puerperalis.

Senger relates a case of uterus bicornis. The right horn was well developed and did not communicate with the left till it reached the vagina. The right cornu was alone fitted for pregnancy, while the left contained blood and other secretions. The history gave an account of severe pain at the menstrual periods. After confinement pain commenced in the left cornu, which became closed, retaining the blood, secretion of mucus, &c., till all assumed alarming dimensions. The sac was first opened and all the purulent matter cleared out, and nine days later the left cornu was extirpated with perfect recovery.

Serous Osteomyelitis or Meningocele?

Schrank relates an interesting case of a child, æt. 4, who, after a fall, developed a swelling about the size of an apple on the back of the head. Fluctuation, pulsation with a walled bony margin, could be easily diagnosed; sometimes it could be moved, which retarded the pulsation. A test puncture revealed a hæmorrhagic fluid with imperfectly-formed round cells. The diagnosis was a meningocele. On opening up the part, the cranium was found to be necrosed with the dura mater swollen out and covered with a cheesy mass, but nowhere could perforation be observed. The diagnosis was changed to sequestral osteomyelitis.

Continental Notes.

[FROM OUR SPECIAL CORRESPONDENT.]

THE "EMPEROR FREDERICK SPRING."

This mineral spring is situated at Offenbach, near Frankfort-on-Main, Germany. The borings in connection with it occupied several years, being only completed in 1888. The spring has its origin at the depth of 275 metres in a rocky formation, which is a guarantee that the water is in no way affected by meteorological conditions. When first struck, in February, 1888, the yield was so strong as to immediately give thirty hectolitres per hour. By the autumn of the same year, its discharge (at the surface of the ground) had increased to sixty hectolitres per hour, and now it equals 180 hectolitres per hour. The water is quite clear and colourless, has some free carbonic-acid gas, is sparkling, free from odour, and with a mild, soft, slightly saline, and pleasant flavour. Temperature averaging 19° Cent.

In a report (accompanying analyses of the water made by Dr. T. Petersen, of Frankfort, Dr. Hintz, of Wiesbaden, and himself), Professor R. Fresenius, of Wiesbaden, states, "The Emperor Frederick Spring at Offenbach-on-Main; forms an intermediate link between the mineral waters, described in balneological phrase as alkaline-muriated waters, because of their chloride of sodium and bicarbonate of soda ingredients, and those designated alkaline-sulphurous waters on account of their containing, in addition, sulphate of soda. The Emperor Frederick spring is distinguished by its relatively *high percentage of bicarbonate of lithium;* it differs likewise from similar mineral waters by its very small percentage of bicarbonate of lime, bicarbonate of magnesium, biroto-carbonate of iron, and of free carbonic-acid gas."

A bacteriological examination made in the laboratory at Wiesbaden, by Dr. Fresenius, of the water specially taken for this purpose by Professor Hueppe, M.D., Director of the Bacteriological Section of the Wiesbaden Laboratory, proved the Emperor Frederick spring to be totally free from germs.

In a pamphlet containing the opinions and experiments of eminent Continental medical authorities (which can be had free, as also sample bottles, from Messrs. Ingram and Royle, Limited, of London) are strong recommendations of the Emperor Frederick spring for the removal of the secretions of uric acid, gout and stone in the kidney, catarrhal affections of the respiratory and digestive organs, gastric catarrh following influenza, chronic interstitial nephritis, renal calculus due to uric acid, arthritic troubles, dyspepsia, &c., &c. The Emperor Frederick spring is greatly commended as a table-water, being very pleasant to drink, digestible, preserving (in bottles) its purity, flavour and sparkling characteristics for many years unchanged, and, although for a long period continuously and most freely drank, it produces no deleterious after effects.

The Operating Theatres.

WESTMINSTER HOSPITAL.

Operation on a Case of Acute Necrosis of the Femur.—Mr. **William Turner** operated upon a boy, æt. 3, who had been admitted eleven days previously with a sinus on the outer side of the left thigh at the junction of the lower and middle third, which was discharging very freely; the temperature was 102°, and the child was suffering from signs of septic absorption. There was considerable thickening of the bone in this region, and the knee-joint contained a small quantity of fluid. The history of the case was that the child had a fall in July, and was severely bruised below the trochanter on the left side; this got better, but early in August an abscess formed just above the knee, which pointed and was opened. On September 6th, the day of admission, the sinus was enlarged and found to go down to the bone, and a flake of necrosed bone removed, but as the child was extremely collapsed it was decided to postpone further treatment until his general condition improved, which occurred, but the local condition did not improve, and onthe day of operation there was abundant discharge of pus, and the swelling of the lower third of the thigh had not diminished. Chloroform was administered, and the skin having been thoroughly purified, the sinus was explored with a probe, which immediately struck bare bone; the opening was then enlarged downwards and upwards, and the outer surface of the lower third of the femur found to be stripped of periosteum as far as the linea aspera; the probe then passed in front of the bone into a large sub-periosteal abscess on the inner side, which was evacuated and drained by a second incision on the inner side of the thigh, just in front of the line of the femoral artery. A gouge was then used to open into the medullary cavity of the bone, which was found to contain pus and breaking down medullary tissue; this was enlarged upwards with cutting forceps until healthy medulla was reached, and the whole purulent material scraped away with a sharp spoon, until nothing but a shell of compact bone remained. The cavity was well washed out with sterilised water and stuffed with gauze soaked in iodoform and glycerine emulsion, and the ordinary dressings of double cyanide gauze and salicylic wood applied. There was a considerable amount of oozing during the operation and the child was very collapsed, necessitating the exhibition of hot brandy and water as a rectal injection and a hypodermic injection of strychnine. Mr. Turner said that the case was very instructive, and had many points of interest connected with it; it was undoubtedly a case of acute necrosis, or better, infective panostitis, in which suppuration supervenes on an injury without any open wound, *i.e.*, the micro-organisms infect the injured part from within—then, owing to the fortunate circumstance that the subperiosteal abscess on the outer side had made its way to the skin and the abscess was opened, the knee joint below and the rest of the femur above had not become infected, and so the condition was more or less localised, and thus for more than six weeks had been running a somewhat sub-acute course, during which time no severe constitutional complications such as pyæmia or septicæmia had supervened. Mr. Turner then pointed out that the operation for cases such as this consisted essentially of two parts, first the evacuation and thorough drainage of the sub-periosteal abscess, and then the opening-up of the medullary cavity and removal of the pus therein, *i.e.*, the treatment of the suppurative periostitis as well as the osteomyelitis; and the treatment of the former without the latter only leads to the disastrous result of either spreading osteomyelitis and central necrosis of the whole diaphysis, or more likely to pyæmia. He explained that it was impossible to remove all the compact bone affected, most of which would in this case ultimately necrose; as if so, two results would follow, first a fracture of the bone would be produced, and secondly, the periosteum would fall together and lay down a very small amount of bone, probably not strong enough to form a new femur for the patient's weight. Mr. Turner then discussed the prognosis, and stated that he considered it very serious. First, as to the life of the patient; his age (only 3), his prolonged illness of over six weeks, and the shock of the operation made the general condition extremely grave; but he hoped that with care the child would improve, and, provided that he did not get any general septic infection, as septicæmia, pyæmia, or hectic, would ultimately recover; and secondly, as to the local condition; here many complications might occur, especially the spreading of the suppurative process into the healthy medulla, or into the knee-joint; and, later, the damaged periosteum might be unable to lay down a new bony femur, owing to the destruction of the osteoblastic layer. Any of these three would probably only be satisfactorily treated by amputation; and, again, the epiphysis was in close proximity and might become affected either from the inflammatory process or from injury during an operation. At the best the boy would have to be operated on again to remove the dead bone, which was already present, but unable to be removed. He further observed that it was most essential to understand the pathological process before attempting to operate on cases of this kind, the suppurative osteomyelitis being most likely to be overlooked; and that a good result depends first on the thoroughness of the operation and great care in the after dressings, so as to be ready for any emergency.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 24, 1902.

THE FUTILITY OF UNDIRECTED OBSERVATIONS.

In a paper on meteorological research read before the British Association last week by Professor Shuster, the author insisted on the futility of undirected observations, adding that "science is bred on routine, and drudgery is often its highest ambition." He pointed out that recent advances in the science of meteorology very rarely depended on the accumulation of vast quantities of material; indeed, he was of opinion that science had advanced "in spite of the observations and not on account of them." These remarks, it is to be feared, might with equal justice be applied to medical science, which, like meteorology, is in danger of being weighed down by the accumulation of unclassified and undigested observations. We are at present groping in the dark in many departments, and we go on observing everything, and for ever, in the hope that at some time in the future the observations may prove useful. Our whole point of view in this respect requires altering. As the Professor urges, we ought to fix on our problem first, and then provide the observations which are necessary for the solution of the problem. It is quite conceivable that concentration of attention for comparatively short periods of time on special questions might yield better and more practical results than heterogeneous observation on a large scale. Mere data, that is to say observations made for their own sake and not for some definite scientific object, are useless, indeed worse than useless, because they encumber the shelving space in our brains which, after all, is not unlimited any more than the shelving space in our libraries. Mere facts are like bricks, which merely occupy useful space until they are sorted and placed in position by the builder. The value of food to the organism is not directly proportional to the quantity ingested, but to the amount digested and assimilated. It follows that in recording observations every effort should be made to explain and elucidate their bearings on some problem which awaits solution. The faculty of careful observation is not rare, but the ability to co-ordinate observed facts and to make them contribute their quota to the advancement of medical science is one of a much higher order, inferring, as it does, an intellectual capacity vastly in excess of that required for even minute observation. We see this clearly enough in the evolution of "new diseases," new, that is, in the sense that, although the individual symptoms and lesions had long before been observed, their relationship and interdependency had escaped recognition until a master mind gathered up the stray threads and demonstrated their pathological unity. The principal phenomena of renal disease must have been familiar to physicians for many years, but their observations bore no fruit until Bright, making observations of his own with a definite object in view, succeeded in proving the association of certain symptoms with particular organic lesions. It may be urged, on the other hand, that the making of observations with a definite object in view is a procedure as fallacious as that of asking leading questions, in that the observer is but too apt to place a construction on his discoveries in harmony with his preconceived idea. But to have a definite object in view is not the same thing as to have a preconceived idea. The observer with a definite object asks himself, Is it so or is it not? whereas the fixed-idea man seems to say, Is it not so? We must not set to work to collect facts in support of a hypothesis, but must conscientiously take into account the facts which militate against it, as well as those which tell in its favour.

CRIMINAL ANTHROPOMETRY AND THE COMMON SERJEANT.

The introduction of scientific methods in criminal procedure may safely be said to have ushered in a new era so far as the identification of individuals was concerned. Hitherto, the police were perforce compelled to trust to written records and to memory of colour, features, height, and other details subject in the nature of things to more or less variation. The patient genius of Bertillon, however, changed all that by the elaboration of the system of anthropometry, which is infallible, at least, so far as any technical test of the kind can approach infallibility. The Bertillon system has been years ago described in the columns of The Medical Press and Circular, and its adoption strongly urged upon the Government of this country. The method in question, it is hardly necessary to remind our readers, depends upon a number of measurements, such as the radius, the phalanges of the digits, the cephalic lines, the cornea, the skin surface of the finger-tips, and other parts of the body that remain constant under ordinary conditions. By reference to the Bertillon record the identity of a prisoner may be determined, humanly speaking, with absolute safety. At the same time it should be carefully noted that the essence of the system lies in the grouping together of the peculiarities of each individual. Thus, twenty men may have a right radius of precisely the same length, and five of them be further possessed of second phalanges of the right index finger of corresponding length, but these five might all be differentiated by their occipito frontal dimensions and by their finger-prints. It is evident, therefore, that to trust to any single detail is to court fallacy. Bearing these points in mind, it is interesting to note some of the early fruits of the adoption of the Bertillon system in the United Kingdom. The case of Harry Jackson, recently sentenced to seven years' penal servitude by the Common Serjeant, is sufficiently startling. The case against accused appears to have been weak, and the whole sentence hinged on his identification by means of some finger-prints. If judges and juries in future propose to depend on isolated facts of this kind we have no hesitation in saying that the door will be at once opened for grave miscarriages of justice. To convict a man upon his finger-prints alone would be to reduce the Bertillon system to a sham. Besides, we have not even the assurance that the finger-prints were recorded by an expert medical authority. To sentence a man to seven years' penal servitude for a small offence against property is, in our opinion, a savage and unjustifiable punishment. To do so upon the strength of a system so mutilated as to be practically worthless is to reduce British justice to the level of a farce. If the Home Office does not wish to become the laughing-stock of more logical countries the sentence upon Harry Jackson will be speedily revised. It is to be hoped that some member will call the attention of the House of Commons to the subject immediately upon the reassembling of Parliament.

THE ANTI-MOSQUITO CAMPAIGN.

Some recently-published statistics direct attention to the expenditure of time, labour, money, knowledge, and intellectual abilities, which are being devoted to the problem of the destruction of the malaria-bearing mosquito by the Governments of the United States and Great Britain. Mr.

L. O. Howard, of the United States Department of Agriculture, refers to certain communities where, throughout the summer, and especially in the autumn, there are two or three cases of malaria in every household. Of every 100,000 deaths which occurred in the United States "from all causes," in 1860, 3,976 were attributed to malarial fevers. In 1880, this proportion had fallen to 2,673. In the year 1892 the statistics of our Indian Empire attributed 5,000,000 deaths to "fever"—a very high percentage of the fevers of India are always malarial. In 1897, nearly one-third of the members of the British Army in India were treated in hospital for malarial fevers and their sequelæ. In Italy it is estimated that 2,000,000 of the population suffer annually. The average yearly death-rate in that kingdom, from 1887 to 1897, from malaria alone was 15,000. And the recorded actual *death-rate* from malaria is but a faint expression of the suffering and misery which are caused by the varied effects of the poison of this plague. There is no way of obtaining a trustworthy record of the number of persons whose constitutions are hopelessly wrecked, or who are partially disabled, or—permanently or temporarily—incapacitated for work by the infection. If there were, the data so obtained would surely be startling. What makes it so excessively difficult to obtain good malarial statistics is, that this pestilence displays its worst ravages in remote rural districts. If Charles Dickens had lived to see this day, he would —peradventure—have been glad. If he had been gifted in his life-time with sufficiently telescopic foresight, he would probably have added, in his own inimitably graphic way, a most effective and important feature to the thrilling landscape picture which he has bequeathed to us of the promised Western City of *Eden*, as it flashed upon the bleared eyes and sinking hearts of Mark Tapley and Martin Chuzzlewit. Within and around the group of uncouth cabins which formed that "city" of the malarious swamp, he would have placed swarms of hungry mosquitoes, ready to pounce upon the newly-arrived and full-blooded English adventurers; and to inject into the blood of the latter, in heartlessly treacherous compensation for the portion which they had withdrawn by suction, the zygoblasts of the now familiar germ of malarial disease. The picture of an ague-stricken district drawn by the immortal novelist is a true as well as an impressive one. And such localities exist not only between and near the tropical zones, but far off to north and south. The whole northern half of the Australian continent is so characterised; and, in the Northern Hemisphere, the low situation of Holland and Belgium insure a liberal share of malarial infection. There are spots even in Sweden and in Siberia patronised by this plague; and—we are told—in Greenland! We confess to a desire for very special corroboration in the last case. The fenny districts of England and the margins of the great bog of Allen, in Ireland, are, we believe, not even yet quite free from "the shakes." The shores of historic Clontarf knew it more than eight centuries after the expulsion of the Danes. Mr. Howard tells us that "there still exist, in many portions of the United States, localities where quinine is a daily article of diet, and where the recurrence of the fever and the shaking-fit are as implicitly to be relied upon in most families as the rising and the setting of the sun. The emaciated form, the sallow colouring, the yellow eyeball, and the utter indifference to the world at large which result from malaria when almost chronic, still characterise almost the entire population of certain more or less restricted portions of the United States." And now that the campaign against the malaria-bearing mosquito has commenced in good earnest, we hope that it will be carried out without intermission —and without mercy—to the end.

Notes on Current Topics.

A Much-Criticised Vaccination Report.

THE report which has been submitted to the Metropolitan Asylums Board by Dr. W. J. J. Stewart, bearing on the vaccination of workmen at the Gore Farm Lower Hospital, has afforded much material for discussion by the anti-vaccinationists. The first point to which exception is taken is the payment of five shillings per head to the men to induce them to consent to be vaccinated. It is regrettable, of course, that it should be necessary to bribe men to acquire immunity to a frightful disease, but the fact remains that, without some such inducement, many of them are too short-sighted and indifferent to submit thereto, and it is obviously vastly more economical to get their consent even at this price than to be saddled with the expense of maintaining a certain proportion of their number for many weeks. The next point is the large proportion of vaccinated men who developed septic complications. This, however, has nothing to do with vaccination, being merely the result of want of care and of defective personal hygiene. Three of them, it is noted, were laid up with "pustular eczema," whatever that may be. It is possible that vaccination, like any other temporary disturbance of the general health, may precipitate an outbreak of eczema in those predisposed thereto, and three is not a large proportion among 503 beer-drinking workmen. Lastly, some 28 per cent. of the vaccinated were disabled for a variable space of time, a point upon which great stress is laid, as though it were not obvious that even an "average arm" must needs entail some disablement in men engaged in hard manual labour, a comparatively trifling amount of inflammation sufficing to incapacitate such persons, especially when their wages are to be paid whether they work or not. The report illustrates the difficulties which would be entailed by any scheme of revaccination undertaken on a large scale at one time. If proper provision were made for compulsory revaccination at a stated age, the inconvenience being spread over several years would be reduced to manageable proportions. We are, however, confronted with the objection that if labouring men are to be required to undergo revaccination, some provision which will enable them to live during the period of incapacity for work appears indispensable. If, however, all persons were revaccinated, say at the age of twenty, the inconvenience would be reduced to a minimum. An aching tooth cannot be extirpated without pain and subsequent distress, nor can we obtain immunity against small-pox without some slight sacrifice of comfort.

Fraudulent Misrepresentations and Promises to Marry.

When a man marries he takes the woman "for better or worse"; the law assumes that he has taken cognisance of all moral and physical qualities and shortcomings, short of extreme anatomical defects, and that he is prepared to enjoy, or, at any rate, to endure, them. He is no longer entitled to plead that the woman he has selected is not of the "nature, quality, and substance demanded," still less is he entitled to plead fraudulent misrepresentation on the part of the lady unless this bear on the essential conditions of the legal union. It is for the prospective husband to make sure that his prospects of matrimonial happiness repose on a sound basis. Presumably, therefore, he would be entitled to plead "disillusion" at any period previous to marriage should he discover that his *fiancée's* teeth were artificial, her hair very largely adventitious, and that, in other respects, her charms were unduly enhanced by meretricious arts. These reflections are suggested by an action for damages in respect of breach of promise of marriage recently tried in the High Court of Justice at Bombay. The defendant urged in justification of his change of front that the plaintiff had fraudulently concealed from him the fact that her teeth and gums were diseased, and that the former were mostly artificial. It is, obviously, a rather risky defence to make, because unless successful the jury might consider that the defendant was adding insult to injury. Nevertheless, it would have been interesting to have a judicial pronouncement on this very delicate subject. Not improbably a sympathetic jury would confirm the adage that "all's fair in love and war," in other words, that Jove laughs at lovers' perfidies. Unfortunately for our information the defendant "climbed down" at the critical moment, and consented to offer the heartbroken plaintiff a substantial sum by way of compensation. The precise extent to which women may artificially enhance their charms and disguise their infirmities remains, consequently, a moot question, and in practice it will be found more convenient to abstain from promising marriage until all doubts have been removed than to seek to evade its realisation by pleading fraudulent misrepresentation.

Coleridge on Cancer Research.

That worthy but misguided enthusiast, the Hon. Stephen Coleridge, continues to fulminate his illogical decrees against orthodox medical research. In one of his latest communications to a London newspaper he attacks the Middlesex Hospital because it chronicles no practical advance in the treatment of cancer in its recently-published volume of special research. The vials of his wrath and satire are chiefly poured out upon the technical description of the blood in cancer. "The utter failure of these researches," he complains, "is delivered to the world in a language that includes such terrific words as these: 'polymorphonuclear leucocytes,' 'eosinophile,' 'poikiloblasts,' 'megaloblasts,' &c." In the non-progressive profession of law, with which this enthusiastic gentleman is connected, we can readily understand there is little need of new words or phrases to describe with accuracy the fruits of fresh discoveries. Scientific medicine, however, is content with the patient accumulation and record of facts and of careful reasoning therefrom. Some day, there can be no doubt whatever that medical men will discover the cause and the cure of cancer. That they will achieve the victory in their own way is equally certain. The alternative routes of investigation suggested by the Hon. Stephen Coleridge are precisely those that would appeal to a scientifically ignorant and untrained mind—to wit, the consumption of meat, tobacco, beer, salt, and the use of curative antitoxins. Fallacies of the kind suggested by this shallow critic of medical methods would be excluded from the essay of an average medical student, to say nothing of the highly-cultivated and candid minds of our skilled scientific investigators.

Earrings Again.

It is stated, on the authority of certain Society papers, that the practice of wearing earrings, a fashion which, we had hoped, had definitively fallen into disuse, is to be revived, the example having been set in high quarters. We trust the announcement is a silly-season invention, since, from every point of view, this relic of a barbarian ancestry stands condemned. Even when the custom was in full swing, that is to say, in the crinoline and ante-crinoline days, people felt it necessary to attempt to justify the mutilation on other than purely æsthetic grounds, and a legend gained currency to the effect that the wearing of earrings afforded immunity against certain chronic inflammatory conditions of the eyes, or, rather, of the eyelids. It is hardly necessary to observe that the belief has no scientific foundation, seeing that such inflammatory affections are, almost without exception, of infective origin, and are amenable only to antiseptic medication and general hygiene. This particular phase of self-embellishment is only one step more ridiculous than the bediamonded crescent which elderly ladies flaunt, without reflecting upon the original significance of that souvenir of Diana, the huntress, and the pictorial tattooing dear to the artistic imaginations of savage peoples. Formerly an integral part of all feminine decoration, earrings have for many years been patronised only by the feather-adorned maidens of the East End, and it would indeed be a strangely retrograde step should their use again become general.

Education and Self-Control.

There is no question on which it is more difficult to obtain any agreement than that of the aim of education. Too often nowadays, amid the multiplicity of the subjects that engage our attention, we are apt to slip into the assumption that the education of the young should be simply an endowing of them with useful information, to be afterwards turned to account in the earning of their living. Nothing is farther from the truth than this. Even from the most extreme "bread-and-butter" point of view, the character of a young person entering on life is of vastly more importance, in regard to his prospects in the world, than the quantity of knowledge he has stored up, and consequently the development of character more than the imparting of information should be the aim of a good teacher. And whether viewed from the individualistic or the socialistic side, no point in the character is of more value than the habit of self-control. "He that ruleth himself is greater than he that taketh a city." The whole subject is well discussed from the point of view of an alienist, by Dr. Hattie, of Nova Scotia, in the August number of the *Canada Lancet*, and we are thoroughly in agreement with his conclusion that not only is self-control "a potent agent in the prevention of mental disturbance, but also a very important factor in determining recovery from an attack of mental disease."

The Psychology of Modesty.

Much has been written concerning the advantages of a "mixed audience" in the maintenance and development of modesty. In the special reports on Educational Methods in the United States, recently published, the headmaster of Keswick School deals with the question of the education of both sexes in one institution. He holds that such would be favourable to refinement and morality: "Richter's sentence, oft quoted in America, puts the case concisely, 'To insure modesty I would advise the education of the sexes together; for two boys will preserve twelve girls, or two girls twelve boys, pure amidst coarse jokes and suggestions merely by that instinctive sense which is the source of natural modesty. But I will guarantee nothing in a school where girls are alone together, and still less where boys are. The monastery system is the one point where our boarding-school system touches the French, and probably it is the worst." In the best interests of the highest sexual development it is most desirable that all that makes for the retention of true modesty should be encouraged.

The Silly Season in Medical Journalism.

The alert medical man, on reading the above heading, will at once prick up his ears and ask, What is the silly season in medical journalism? Let him take comfort and learn that, like the snakes in Iceland, there is no such season in the workaday world of medicine. This particular science is progressive fresh facts are discovered daily, and the ball lies at the feet of every investigator in this, the greatest of all intellectual pursuits. At any moment it may be given to the humblest practitioner to make some observation that will confer on him the laurels of immortal fame. The medical journal, as a matter of fact, has the command of a vast range of subjects, scientific and social, which are full of living interest and actuality. In the lay newspapers, at certain times of the year, the big gooseberry jumps into prominence as a topic of entrancing interest. Recently we have seen variations by way of huge marrows and melons five feet long. It is a poor medical journal, however, that has to fill its space with trite and trivial gossip of that texture. The world of medicine and its workers live in a whirl of events of multitudinous variety, the consideration of which affords material for every faculty of the mind

The "Moorfields" Eye Hospital and its Finances.

The Committee of the Royal London Ophthalmic Hospital, better known to the world by its old name of Moorfields, continues to call attention to the financial straits of that institution. The trouble arose from selling the enormously valuable old building, where they lived rent free, and by their subsequent emigration into another district, where the hospital became quickly swamped by the burden of local rates and the cost of bricks and mortar. The committee have themselves to thank if they are compelled to close the hospital, a step that is announced as not impossible in the near future. Their position is of value in reference to the announced sale of the Royal Orthopædic Hospital in Oxford Street. Here also an enormously valuable site has been disposed of without compulsion, and the institution is to be removed to a distance. The sale has been strenuously opposed by a section of the governors and by the medical journals, but has nevertheless received the sanction of the Charity Commissioners, who are presumed to have the interests of the chartered medical charities at heart. We shall watch with interest the upshot of the sale of both these hospitals, especially as no satisfactory reasons for the sale have been vouchsafed in either case.

Primary Carcinoma of the Vermiform Appendix.

Vestigial structures are, to a great extent, exempt from neoplastic formation. It was formerly held that the cæcal appendix was an embryonic remnant, and certainly up to recent years but few cases of growth arising in it have been noted. Examples, however, are gradually accumulating. Dr. D. S. D. Jessup (*New York Medical Record*, August 23rd), after recording a case of adeno-carcinoma of the cæcal appendix, gives brief references to thirteen cases which he has been able to collect from medical literature. Nine of the cases were females. Two cases were under twenty years of age and four under thirty. There was a history of appendicitis in seven. In no case does the growth in the appendix seem to have been diagnosed during life. The opinion is expressed that routine microscopical examination of all the appendices removed will doubtless in the future show that carcinoma occurs in the appendix more often than has hitherto been thought.

The Matriculation Examination of the University of London.

We are requested to call attention to the fact that it is no longer *necessary* for candidates for degrees to have passed the Matriculation Examination. As will be seen by reference to pages 14 and 29 of the "Revised Regulations for Matriculation," exemption from this examination is under certain circumstances granted to graduates of British Universities and of the more important colonial and foreign Universities. The full text of the Statute and the Regulation governing this exemption is set forth on page 29. In future the Matriculation Examination will be held three times a year instead of twice—in January, in June (or July), and in September. The examinations in January and June (or July) may be held not only at the University, but also, under special arrangement, in other parts of the United Kingdom and in the Colonies, but that held in September is conducted solely in London. No examination will be held after June next under the old regulations.

Albuminuria and Exercise.

The occurrence of albuminuria in health is always a possibility to be remembered, and in no case should a physician be satisfied with one examination of the urine when he has to base an important decision on the presence or absence of albumen. The association of the excretion of proteid with severe muscular exercise has been investigated by Leube, Stirling, Levison, and others, and their observations go to show that albumin very commonly appeared in the urine immediately after exertion, while no relationship with the food taken could be established. A very valuable investigation of the same nature has been concluded recently by Messrs. Dunhill and Patterson, medical students at Melbourne (*Intercolonial Medical Journal*, July 20th), who made a systematic examination of the urine of a boat's crew under severe training, and of a hare-and-hounds team after a long race. In the latter set, a distinct quantity of albumin was present in the urine of each competitor, while in a control experiment in the absence of exercise on the urines of the same persons, no albumin whatever was detected. Most of the rowing men also excreted albumin after exercise, and the quantity bore a very marked proportion to the work done. The authors of the paper quoted are to be congratulated both on the value of their results and on the excellent manner in which they are published.

Surgical Toilet.

The development of the personal toilet of a surgeon in preparing for operating has lately advanced on the Continent to a degree we are unfamiliar with in this country. The newspapers have just been telling us that surgeons who obey rigidly the dictates of asepsis must devote their beards in the interests of their art; but we think few, if any, of our surgeons at home have as yet done so. In these countries, surgeons when preparing to operate do little more than put on a sterile coat and cleanse and disinfect their hands thoroughly, though some are in the habit of wearing gloves, either of cotton or rubber. Not so with our German friends, who endeavour to hedge in the insiduous microbe by arming themselves literally *cap-a-pie* in sterile clothing. We quote a full description of the ritual observed in the Breslau Clinic from a recent article by Mr. Purves, of Edinburgh (*a*):—"The surgeon and assistants remove coats, &c., in the anteroom and put on goloshes. The seniors also put on clean linen trousers. (Why not the juniors?) A preliminary cleansing with hot running water, soft soap, sterile nail-brush, nail-scraper, and scissors is carried out for five minutes. Then a fresh nail-brush is taken, and for a second period of five minutes the hands and arms are scrubbed with the soap spirit. This being completed, some sterile water is poured over the hands by a nurse, and cultures are taken from under the nails and nail-folds of each hand and two tubes inoculated. Then the surgeon with a foot-lever raises the lids of various drums and arrays himself in (1) a sterilised mantle reaching to the feet; (2) a cap; (3) merino sleeves, which extend upward from the wrist to over the ends of the mantle sleeves; (4) a mask, which is fixed on by an attendant; (5) cotton gloves."

The Monetary Cost of Consumption.

It is calculated that we spend in the United Kingdom upwards of a million sterling every year, through the poor-rates alone, on the victims of pulmonary tuberculosis. Moreover, of the 42,000 who die annually of this disease, the majority are between twenty and forty years of age, that is to say, they are lost to society just when they are in a position to make good the cost of their maintenance and education. The mere loss in wage-earning power is estimated at from ten to twelve millions annually. It follows that any means, however costly to begin with, which will have for effect to materially reduce this prodigious waste of life and working energy, ought, in the end, to prove a remunerative outlay to the community.

Hirsute Surgeons.

A movement is on foot, especially in Germany, to compel surgeons to abstain from wearing moustaches and beards, on the ground that these appendages are capable of carrying pathogenic microbes into the operating theatre, thus frustrating the endeavour to render all operations aseptic. To be logical, an edict

---

(*a*) *Edinburgh Medical Journal*, September.

ought to be passed condemning them to shave the scalp as well, since their flowing locks are fully as open to objection as the beard. From this point of view baldness, it is suggested, constitutes a special qualification for surgical practice as well as an outward and visible manifestation of extreme cerebral activity, though we are prepared to challenge the assumption that baldness is necessarily the consequence or the indication of a high standard of intellectual attainments.

Medicine at the British Association.

Some very technical papers were read at the recent meeting of the British Association at Belfast. Among them was one by Professor Schäfer, F.R.S., on the diuretic action of pituitary extracts. There is reason to suspect that this curious little body possesses physiological properties of considerable activity, and it is quite possible that in the near future researches in this direction may open up an era in therapeutics as remarkable as that inaugurated by the introduction of preparations of the thyroid gland, the pharmacodynamics whereof were as ill-understood twenty years ago as those of the pituitary body are at present. Dr. John Turner brought forward some interesting results of recent researches on the intimate structure of the grey matter of the cortex. He showed that the pyramidal cells of the cortex are surrounded by a beaded network, the existence whereof had not been previously noted in the human organism, and he also showed specimens illustrating the connecting up of the nerve-cells by an intercellular plexus of nerve fibrils. The latter, however does not strike one as altogether novel. Professor Halliburton contributed an interesting paper on the regeneration of nerves, which tended to prove that repair of nerves takes place from the centre towards the periphery and not "from end to end."

Religion and Medicine.

It is always profitable to note a cultured layman's estimate of the modern practitioner of medicine. Mr. J. Brierley, in his recently-published volume of essays, "Ourselves and the Universe," ably expresses the view of many a thoughtful man as to the medical vocation. He shows that the feeling has grown upon men that this calling to the art of healing, demanding as it does the constant exercise at once of knowledge and of sympathy, and which also presents the most fascinating problems for the intellect, and the most imperious claims upon the heart, and whose aim is the furtherance of life and the defeat of death is emphatically a calling for noble souls, and, as he indicates, noble souls in abundance have flocked into it. "To-day the *personnel*, the standing, and the achievements of the medical profession represent one of the most valuable assets of civilisation." But the essayist does not stop with his praise. He contends that medical science is ultimately a branch of spiritual science, and seeks to show that bodily healing requires a knowledge of psychic as well as of physical conditions; and that, finally, the medical ministry to a diseased and broken humanity can never be adequate unless carried on as a mediation of the eternal goodness and love. It is certain that the old saying, *tres medici duo athei*, if ever it presented a degree of truth, can no longer hold, and doubtless many will find much that will profit them in this latest contribution to the much-discussed subject of the relation of religion and medicine.

Gas Leakage and Ill-Health.

With shortening days and need for illumination during the dark days and long nights of winter it is well that householders and all who employ gas in their houses should previously investigate the pipes and burners under their control. It is generally recognised that gas leakage may prove a serious danger in bringing about fires and explosions, and causing asphyxiation, but it is not so well recognised that a persistent fouling of the atmosphere by the slight escape of gas may be a fruitful cause of anæmia and serious debility. Many servants in kitchens where gas-cooking is in vogue, girls in restaurants where water and eatables are kept hot by constantly burning gas, suffer from various ills dependent on blood-poisoning, and much of the anæmia so prevalent among young females of this class is undoubtedly due in part to gas leakage.

Native Arrow Poison.

Among other interesting results of the sojourn of the Cambridge Anthropological expedition at Sarawak as the guests of Dr. Charles Hose, we have obtained a careful and trustworthy description of the vegetable poison used by the natives of the Baram district for poisoning their arrow-points. The *ipoh* is used by all up-country natives as a generic name for arrow-poison. Its application is very widely spread throughout Malaysia. The composition is not, however, constant throughout. More than one species of *strychnos* and antiaris appear to be used in different localities; sometimes a mixture. Among the Kenijahs of the Baram district, however, it appears that the sole source of the arrow-poison is the famous upas tree—*Antiaris toxicaria*—of romantically poetical, and approximately mythological, reputation. The poison is made by inspissating the juice, and has been found to owe its activity to the presence of a nitrogen-free glucoside, which acts on the cardiac muscle and on the central nervous system. We are promised a future communication from Dr. Seligmann, giving the results of his investigations on its physiological action. The *ipoh* is obtained by scoring the bark of the upas tree in oblique grooves, whose lower ends pass into a single vertical (larger) one; while at the lower end of the latter is placed an obliquely-pointed bamboo tube, to receive the trickling sap. Rolled in palm-leaf, and inspissated by artificial heat, this *ipoh* appears to retain its poisonous powers for years. The arrows, or *darts*, as they are more appropriately called, are made of strips of palm wood, about 20 to 30 cm. long. They are carefully rounded—with a diameter of about 3 mm. Each is provided with a butt of the pith of the sago palm, in the shape of a truncated cone whose base accurately fits the bore of the blow-pipe from which the dart is projected. The blow-pipe itself is from seven to eight feet in length. The natives aim well at a range of twenty yards, and at that distance the poisoned darts penetrated the fairly hard wood of a target to a depth of one-third of an inch.

The Gold Treatment of Tuberculosis.

The use of gold, that approximately universal panacea for the relief of the physical and mental ills which mar so many of the enjoyments of human life, has recently been requisitioned and most favourably reported on as a local auxiliary in defence against an invasion of bacillus tuberculosus. M. G. Bué, in a recent number of *La Semaine Médicale*, states that the general antiseptic powers of chloride of gold are equal to those of the iodine compounds; and that in topical applications it displays a special predilection for the habitat of the great enemy of mankind, the microbe of tubercle. From alcoholic dipsomania to suppurative adenopathy there opens a wide and yawning gulf; yet the magical therapeusis of the precious metal is held to be able to bridge it over. When "the highly experienced and famous chymist, John Rudolph Glauber," prepared his solution of "green Lyon, or wonderful Golden Salt," he announced to the world that "this Golden Liquor being drank, strengtheneth and confirmeth the whole humidum radicale, Stomach, Brain, and all the inward parts of the body, beyond all other medicines which I have hitherto known. Also it expelleth Melancholy, and all anxieties of Mind, taketh away Palpitations of the Heart, openeth obstructions of the internal vessels; it healeth the hurts of the inward parts, as Liver, Lungs, &c., and cureth all inward exulcerations; it cureth Gravel and Stone, whether in the Reins or Bladder; it keepeth the Body soluble; expelleth Wind, with the pains of the Cholick; preserveth the blood from corruption; cureth the Leprosie, Scabs, and Fevers of all sorts; in process of time it taketh away the Gout; to the insulting Apoplexy and Epilepsie it affordeth present cure; it cleanseth the Blood infected by the Scurvy, Plague, and other contagious Diseases; it preserveth and freeth from all internal Ulcers; defendeth the Lungs, Liver, and other parts; and removeth Exulcerations already arisen, and takes them away radically. It so tingeth all the inward parts of a Man with its Balsamic Virtue, that not being easily obnoxious to Diseases, they enjoy a sound and long life. Outwardly used, it healeth all fresh wounds, no less than old and open Ulcers, without any Ointments or Plasters; for in curing Ulcers of this sort, there is nothing in Animals, Vegetables, or Minerals, which answereth to this in Virtue; as also inwardly it cureth Ruptures." This comprehensive statement has left little room to subsequent observers and experimentalists for the discovery of new items of virtue in aural therapeusis. M. Bué uses a solution containing one gramme each of chloride of gold and chloride of sodium in fifty grammes of distilled water. Aspiration and evacuation of suppurating glands and tuberculous osseous tissue are followed by the injection of one c c. of the gold solution two or three times a week. The opening made by the needle is then sealed with cotton dipped in collodion. Four to twelve injections have caused the subsidence of the tuberculous gland in every case. No untoward after-effects have ever been noticed. As a topical application in tuberculous laryngitis, the gold solution has, however, given less encouraging results.

Latent Pneumonia.

In a certain proportion of deaths occurring with comparative suddenness, with little or no warning of the impending catastrophe, one is surprised, at the post-mortem examination, to discover extensive pneumonic consolidation, the existence whereof had not been even suspected. These cases fall into the category of "latent pneumonia," a variety of the disease which is practically confined to alcoholic subjects. Experience has shown that consolidation of one lung almost in its entirety is not incompatible with the patient's having led an active life well nigh to the moment of death. It occurs with most frequency during the bleak winter months, in adults over forty years of age, and most frequently in males. The possibility of sudden death being due to this cause should never be lost sight of in elderly alcoholic subjects, but, on the other hand, the presence of a certain area of pneumonia consolidation does not exclude the possibility of death being precipitated by other causes such as violence.

A "Pupil" Midwife.

A curious condition of affairs was revealed in a London Coroner's court last week in the course of an inquiry into the death of an infant eight days old. From the evidence it appeared the child was jaundiced from two days after birth, and became "yellow as a sovereign." The mother was attended during her confinement by a "pupil midwife" of the City of London Lying-in Hospital, but, in spite of the illness of the infant, no medical man was called in. A post-mortem examination of the body showed rupture of the spleen. Here we have the unqualified midwife with a vengeance, and the irony of the position is a thousand times multiplied by the fact that this culpable or reckless ignorance was paraded under the title of a medical charity. It appears that "pupils" are supposed to call in a medical man in case of illness, but the discipline of the institution must be somewhat lax if it permits a raw "pupil" to use her own discretion as to what constitutes serious illness. It would be interesting if one could trace the origin of the ruptured spleen. The facts of the case, as disclosed to the jury, did not warrant any conclusion as to the cause of the injury. It has long been evident that our lying-in hospital system requires a thorough overhaul.

Important Admiralty Concession to Navy Medical Officers.

We are officially informed by the Director General of the Navy Medical Department, that, in future, the fees (not exceeding £25) of the naval medical officers who undergo a three-months' course of study at metropolitan hospitals will be paid by the Admiralty, in addition to travelling expenses, with lodging and provision allowances according to scale.

PERSONAL.

Dr. Andrew Balfour, of Edinburgh, has been appointed Bacteriologist and Expert Adviser to the Governor-General of the Soudan Provinces at Khartoum.

Major Heuston, C.M.G., R.A.M.C., has been appointed Medical Officer to the Royal Hospital, Kilmainham, and the Royal Hibernian Military School, Phœnix Park.

Sir T. Thistleton-Dyer, K.C.M.G., F.R.S., has been elected the first president of the recently-formed "Therapeutical Society," which will meet on the premises of the Society of Apothecaries at dates hereafter to be fixed.

The Royal Humane Society have awarded to Dr. Cuthbert Eccles, Dispensary Medical Officer of Delgany, Greystones, County Wicklow, the society's testimonial for saving Mr. Lumley from drowning while bathing in the sea at Greystones on June 26th.

Dr. T. H. Milroy, Assistant to the Professor of Physiology at Edinburgh University, has been appointed to the Chair of Physiology at the Queen's College, Belfast, rendered vacant by the appointment of Prof. W. H. Thompson to the same chair in Trinity College, Dublin.

Mr. Rushton Parker, F.R.C.S., Professor of Surgery in University College, Liverpool, will occupy the chair at the annual dinner of past and present students in the Faculty of Medicine, University College, London, which is to take place at the Hotel Cecil on the 1st prox.

Mr. William Miller, of Montreal, Canada, has offered a donation of £500 to the Derry Infirmary to build and equip an operating theatre in the new wing of the institution. Mr. Miller desires that the theatre be regarded as a memorial to his deceased father, who so long and honourably filled the office of surgeon to the infirmary.

Dr. R. C. Brown, the *premier* practitioner of Preston, has received the distinguished honour of being proposed by the Earl of Derby, Guild Mayor of Preston, for admission as an in-burgess of that ancient borough. Dr. Brown's benefactions to local medical charities are well known. The Countess of Derby has recently opened one of the finest operating theatres in the country, which Dr. Brown has built at his own expense for the Preston Infirmary, and to the same institution he has also given an admirable organ. Dr. Brown sets a wise example in personally superintending the bestowal of his numerous benefactions.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

SCOTLAND.

[From our own Correspondent.]

NEW EDINBURGH ASYLUM SCHEME.

This vexed question was discussed at a recent conference between the General Board of Lunacy and the District Lunacy Board, with special reference to a report thereon by Mr. G. T. Hine, architect, London, who was in attendance. The prefatory remarks were made by the Master of Polwarth, who presided, and in referring to the state of matters which prevailed, and which required their very serious attention, he advised the District Lunacy Board to do something as rapidly as possible. His remarks were discreet and full of common sense, and in concluding, he said, "Cut out the expensive matters of detail, get to work at once, and make good, sound, healthy provision for those whom they had to provide for." Surely this does not leave much to be desired, and the Board could not have got more fitting or better advice. At Morningside Asylum there are forty patients sleeping on "shakedowns," and this cannot but be regarded as very unsatisfactory. Then the District Board have over 100 patients boarded in other asylums, and it was very fortunate for them this accommodation was available, otherwise they would have been in a sorry plight.

A meeting of the District Lunacy Board was afterwards constituted, and after a lengthy discussion it was ultimately decided to act upon the recommendations of Mr. Hine and the General Board of Lunacy, and to adhere to stone construction for all the buildings, but modified as regards details, to simplify the interior fittings of the buildings, to reduce the style of finishing in all legitimate ways, to commence building operations as early as possible by erecting an administrative block and infirmaries first. It was remitted to the architect (Mr. Blane) to consult with Mr. Hine and amend the plans, specifications, and schedules in accordance with their views.

The ratepayers of Edinburgh must feel relieved that all the peevish disputes over this scheme have at last been apparently closed, and that there seems a prospect of building operations being commenced soon. For some time an outlay of £600,000 for an asylum, eminently splendid in the extreme, for pauper lunatics has been suspended over their heads, like the sword of Damocles by a single thread, threatening to fall upon them at any moment, and it must be a comforting unction to their souls that the expenditure has been cut down to just one-half that amount. The grandiose ideas of the Board have received a rude shock, the cost per bed having been reduced to £300, exclusive of cost of estate, railway, and water supply, equal to about £150 more per head. We expect the asylum, when finished, will approximately cost about half a million pounds, and as it is urgently required the work should be begun at once.

BELFAST.

[From our own Correspondent.]

The Union Workhouse Scandal.—A meeting of the Board of Guardians was held on September 16th, at which, after several hours' lively discussion, the guardians decided, by a majority of 32 to 1, to bury in oblivion their extravagance in the supply of medicines and medical appliances and the Local Government Board inspector's very outspoken report thereon. The question at issue at the last meeting was the continuance or otherwise of Messrs. John Clarke and Co. as contractors. The Local Government Board inspector said in his report:—"In connection with this matter the action of the medicine contractors, Messrs. Clarke and Co., in deliberately entering into a separate contract and charging special prices for the articles already provided for in the formal contract with the guardians, is open to so unfavourable an interpretation that the Board consider the guardians should, after due notice, convene a special meeting, with a view to determining whether this firm should any longer be entrusted with the contract for supplying medicines to the workhouse. It is hardly credible that large contractors like Messrs. Clarke and Co., who supply drugs to a great number of unions in Ireland, could have acted in ignorance of the terms of their bond, and no adequate explanation was offered by them at the inquiry as to how they came to make these excessive charges." After this "plain talk" Messrs. Clarke and Co. wrote a letter to the Guardians, withdrew it, and substituted another, now published. A more futile document as an "explanation" it would be hard to imagine; it just amounts to this, that they never knew the meaning of the terms in their bond. However, the Guardians charitably swallowed it all, and agreed that the Local Government Board inspector had made a mistake! The minority of one hinted that explanations had been given in private, and that "a lot of underhand influence was at work." But in spite of his protests Messrs. Clarke and Co. are to continue to supply the medicines, and we, poor ratepayers, will continue to pay the bills.

Chair of Physiology in Queen's College, Belfast.—It was announced on the 20th that Dr. T. H. Milroy has been appointed to the Chair of Physiology in Queen's College, rendered vacant by Professor W. H. Thompson's resignation. Professor Milroy had a distinguished career at Edinburgh, then studied at Marburg and Berlin, and for some time has been assistant to Professor Schäfer, at Edinburgh. He attended the Belfast meeting of the British Association, and made a most favourable impression on those who met him.

British Association for the Advancement of Science.—The meeting of the British Association in Belfast opened on Wednesday, Sept. 10th, with the address of the President, Professor Dewar, followed by the addresses of the presidents of the various sections on Thursday. The meeting was hardly so large as the last one held in Belfast in 1878, but otherwise proved a very successful one. It is to be regretted that so few local medical men have taken part in the active work of the Association, as the number of medical men among the visitors is considerable. In Section I.—Physiology—which is the section appealing most strongly to us, papers have been read by Professor Halliburton (president of the section), Professors Schäfer, Page May, Gotch and Symington, and Drs. Edridge Green, Osborne, and Cecil Shaw. In the Section of Anthropology much interest attached to the exhibition by Professor Cunningham, of the skeleton of Cornelius Magrath, the Irish giant. The meetings of the British Association concluded on Wednesday, 17th, with the usual general meeting and votes of thanks.

The smoking concert given by the Ulster Medical Society on Monday, the 15th, was among the most successful of the entertainments. About 230 members and guests were present, and an excellent programme of music was provided. The programme, illustrated with sketches of prominent members of the British Association and their doings, was the source of much amusement.

The Health of Belfast.—The report of the Medical Superintendent Officer of Health for the City of Belfast for the year 1901 has just been issued. It is an interesting document, both for what it includes and for what it omits; both points can be best brought out by a comparison with an English report, and we have on our table the Liverpool report of the same year—a city with less than double the population of Belfast. The Liverpool report contains 227 pages, six charts, and three maps; the Belfast report contains forty-five pages, two charts, and no maps. The Liverpool report contains an index covering six pages, the Belfast report contains no index or table of contents of any description whatever, and if one wants to find what is in it one has to go right through it. Of the forty-five pages in the Belfast report six are taken up with a sort of geographical description of the districts into which the town is divided, and seven with a detailed account of the weather during each month of 1901, interspersed with remarks on the more prevalent diseases: and finally seven pages are filled with a list of the streets in which typhoid occurred, with the number of cases in each street—which, of course, ought to have been shown on a map. These three items, then, supply twenty pages of padding, leaving twenty-five pages for matters of importance. These pages include eighteen tables, of which Table I., showing the number of infectious diseases reported during the last ten years, is one of the most interesting. From this it appears that there were 2,530 cases of typhoid reported in 1901, the highest except in 1898 and 1897. If the 1,351 cases of simple continued fever are included, as they probably should be, 1901 is worse than any year except 1898. Typhus cases numbered fifteen, and small-pox five, while diphtheria and membranous croup reached the serious total of 433. The death rate is given as 22·4, the average for the previous nine years being 23·5. Under the head of "Typhoid," we are told "During the year Dr. J. Lorrain Smith, Queen's College, examined the blood of the patients by Widal's test in eighty-eight cases, and found that fifty-five gave positive and thirty-three negative reaction." This is the only mention we can find of Professor Lorrain Smith's valuable work: his examination in diphtheria cases, as also his examinations of water, sewage, &c., are absolutely ignored. In the Liverpool report twenty pages are devoted to the analytical and bacteriological examinations of specimens of food, milk, &c., but we are left entirely in the dark as to whether such examinations are made here. Similarly we are in the dark regarding the destruction of unsound meat, fish, vegetables, &c., while the Liverpool report gives full particulars in five pages. We have a refuse destructor in Belfast, but it is not even mentioned, and we depend for information concerning it on the sinister rumours as to its being an expensive failure. But it is not only things we are ashamed of that are suppressed, for our excellent ambulance system, of which we have some reason to be proud, is not mentioned either. To conclude, we can only say that this report, emanating from a large and prosperous city like Belfast, is a disgrace to all connected with the Health Department of the city, and we sincerely hope such a poor production will never again be seen here.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

"THE SCIENTIFIC ASPECTS OF THE BACON-SHAKESPEARE CONTROVERSY."

To the Editor of The Medical Press and Circular.

Sir,—In your review of Judge Webb's book under this heading you state that Bacon "was not a man of science at all, and that his scraps of scientific knowledge were derived from sources accessible to every student of that date." This, surely, is an extraordinary statement to make when it is a matter of common knowledge, as Professor Fowler says, that in the particular sciences Bacon threw out many suggestions of rare sagacity, and anticipated more recent discoveries, which Professor Knott ignores. Such were his speculations on colour, his anticipation of the recent theory of heat, his experiment on the compressibility of water, and his wonderful appreciation of the combined unity and variety in nature. To these instances may be added his sagacious and fertile suggestion of a closer union between formal and physical astronomy as well as of the necessity of combining the explanations of celestial and terrestrial phenomena; the remarkable passage on attraction, and the ingenious experiment in connection with it; the brilliant conjecture in "Novum Organum" that the actual state of the starry sky precedes by an interval of time that which is apparent to us, or, in other words, that light requires time for its transmission; the implied criticism of the ordinary doctrine of species contained in a passage on Realism in "Novum Organum" and, lastly, the attempt made in the "Historia Ventorum" to consider the direction of the winds in connection with temperature and aqueous phenomena, on which Humboldt highly compliments him as having thereby laid the foundations of a theory of the currents of the atmosphere. "Bacon the scientist," as you sarcastically call him, performed all these feats, and his death was caused through his passion for science, as he died from the effects of a cold contracted by his leaving his coach to collect snow with which he meant to stuff a fowl in order to observe the effect of cold on the preservation of its flesh, thus anticipating "frozen meat" by a few hundred years. "Bacon the scientist" also wrote, I believe, the "New Atlantis," which suggested the foundation and programme of the Royal Society, as well as of several scientific societies abroad. But these scientific societies, of course, according to Professor Knott, have nothing to do with science. And Bacon also knew nothing about science when he succeeded in laying the foundations of a science for the interpretation of nature which furnish the ground-plan on which all subsequent workers in this department of knowledge have built. So "Bacon was not a man of science at all."

It would be interesting to know where and when Bacon "contemptuously rejected" the views of his medical adviser, William Harvey, regarding the circulation of the blood, and it would be equally interesting to learn where William Shakespeare obtained the scientific knowledge which enabled him to anticipate Harvey's discovery—years before its announcement—when he writes:—

"The ruddy drops that visit my sad heart."
(*Julius Cæsar.*)

"Oh, heavens! why does my blood thus master to my
heart." (*Measure for Measure*)

"I send it through the veins of your blood,
Even to the court, the heart." (*Coriolanus.*)

Voltaire maintained that Bacon forestalled Newton on the subject of gravitation. In a letter to King James, Bacon wrote, "The water and like bodies do fall towards the centre of the earth," and "iron trembles under adamant." Curiously enough, at the same time, the same discovery was made by Shakespeare in the vow of Troilus, who says he would be true to Cressida "as iron to adamant, as earth to the centre," and that Cressida's love

"Is as the very centre of the earth,
Drawing all things to it."

You say that Bacon's "scraps of scientific knowledge were derived from sources accessible to every student of that date." Can you give me the source of the following scrap, taken from Bacon's "Description of the Intellectual Globe?" (1611)?

"I am the more induced to set down the History of the Arts as a species of Natural History, because an opinion has been long prevalent that Art is something different from Nature, and things artificial from things natural. Whereas men ought, on the contrary, to be surely persuaded of this—that the artificial does not differ from the natural in form or essence, but only in the efficient; . . . it is Nature which governs everything. . . . All I mean is that Nature, like Proteus, is forced by Art to do that which, without Art, would not be done." In 1611, then, Bacon declared that "Art is Nature." In the very same year "A Winter's Tale" is written, and in this play we find the following:—

"Yet Nature is made better by no mean.
But Nature makes that mean: so over that Art
Which you say adds to Nature, is an Art
That Nature makes . . . .
This is an art
Which does mend Nature, change it rather, but
The Art itself is Nature."

Can a third earlier or contemporary parallelism be found enunciating the axiom that "Art is Nature"?

Bacon received his scientific and philosophical knowledge from study. Shakespeare obtained his from "intuition," which, according to Cowden Clarke, "taught him many secrets of Nature as yet unpromulgated by science to the world, as well as many of those known only to adepts in their several branches of science"; from "the study of the "infinite book of Nature," according to Halliwell-Phillipps, and from "heaven-sent inspiration," according to Theodore Martin. Very likely!

I am, Sir, yours truly,
GEORGE STRONACH.

Edinburgh, September 20th, 1902.

"THE NOMENCLATURE OF SURGICAL OPERATIONS FOR UTERINE TUMOURS."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I read with pleasure Dr. Giles' gentlemanly reply to my suggestions, and I have waited some little time in order to give others the chance to say something about the subject, but I am much afraid that the nomenclature of surgical operations is anything but a matter of interest to the bulk of practitioners. I need not say that I consider this a very great calamity indeed, since it is a pretty substantial evidence of the state of knowledge, or rather lack of knowledge, of those languages which constitute the basis of our professional names in both medicine and surgery. "Little Latin and less Greek." As a matter of fact, long-nebbed names as a rule are a stumbling-block and an abomination to the ordinary medical practitioner, and this has always been the case.

The names that survive and come into general use are the simplest, and preferably English adapted words, both for diseases and operations. On this consideration, then, I think, Dr. Giles misses the point. I can agree with him in the accuracy of his use of the words he proposes now for operations, and if I had my way I would simplify and epitomise a great deal of our work by using such words. But I can see perfectly well that in the present state of education it would be quite impossible to introduce such words generally.

I certainly would insist on a much greater knowledge of the Latin and Greek medical writers in their own languages, but it is plain there is not the least possibility of carrying that out at the present time.

Therefore, what I did propose was, that only the simplest words should be used for indicating operations, and that no combination of words should be used implying or containing a description of the operation done, nor of the disease for which it was done. This brings me again to the statement that if this plan were adopted in gynæcological surgery it (gynæcology) would then become spontaneously a branch of ordinary surgery, and the descriptions of the operation and of the disease would fall entirely into their own places.

For instance, in an operation for club-foot, no combination of words is used to indicate both operation and the condition of the foot. The operation will be called "Tenotomy," while the disease may be "Talipes equino varus"; or, going from the foot to the head, the operation on the skull would be called "Trephing," quite independently of what the disease may be.

I need not elaborate this; I merely wish to emphasise that it would be better in the interests of surgery, and especially of gynæcological surgery, first, to keep the names simple; second, not to mix up the nomenclature of operation with that of disease.

I am, Sir, yours truly,
J. STUART NAIRNE.

268, Renfrew Street, Glasgow,
September 15th, 1902.

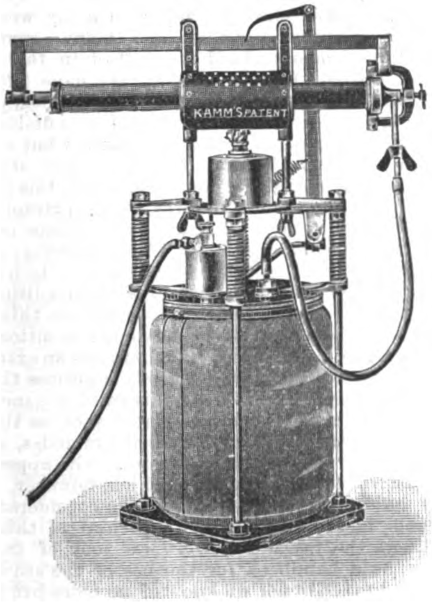
Royal Army Medical Corps.

THE Secretary of State for War has allowed that candidates for commissions in the Royal Army Medical Corps who are over the regulated limit of age at the date of the competitive examination shall be permitted to deduct from their actual age any period of service in the field after October 1st, 1899, that they would be allowed to reckon towards retired pay and gratuity if such deduction will bring them within the age limit.

New Inventions.

OXYGEN AS A THERAPEUTIC AGENT.

Oxygen has been clearly demonstrated to be a valuable therapeutic agent in the treatment of various ailments. Its service in expediting the healing of ulcers has been fully demonstrated; many cases of serious anæmia have benefited by its administration, but it is particularly in acute affections involving the respiratory apparatus that it has proved most distinctly advantageous. Not a few cases of pneumonia have undoubtedly been saved through its instrumentality, and in many instances of laryngeal involvement, chronic bronchitis and emphysema, and certain other pulmonary lesions, oxygen has won its position as a trustworthy agent. In towns but little difficulty is experienced in obtaining an adequate supply of oxygen in cylinders, but in country districts and isolated parts this is not the case For such the new Medical Oxygen Generator invented by Messrs. Kamm and Co. should prove of great service. We have carefully examined the new apparatus and find it to be a simple, convenient and trustworthy means of generating oxygen in quantities sufficient to meet the needs of medical cases.



Literature.

MASSAGE IN RECENT FRACTURES. (a).

The prolonged stiffness of limbs and the immobility of joints after fractures have always been a great source of trouble to the patient and considerable anxiety to the surgeon. Any treatment therefore which is safe, easily applied, and that will lessen the prolonged splinting which is the invariable rule in fractures of the limbs, ought to be hailed as a great boon in this department of surgery.

The little work before us, which we have carefully perused with much pleasure and profit, consists of a course of Four Lectures, including an introduction and an appendix, delivered by the author at St. George's Hospital, and which were subsequently published in the *Lancet*, and, as a second edition, now appears with further illustrations and additions.

The use of massage, and early movements in recent fractures, was originally introduced by Lucas Championière, a well-known French surgeon, and the author has been the strong advocate of the method in this country. In safe and skilled hands, we can easily understand how useful such a treatment might be in an uncomplicated case, to prevent matting of the tissues, wasting of the unused muscles and stiffness of the joints, above and below the fracture.

But in cases where the treatment is undertaken by a tyro or "prentice hand" we would be afraid to anticipate the disastrous results which might possibly follow.

The author shortly describes his treatment as follows when he says: "The method comprises three stages. 1. Gentle rubbing in an upward direction over the fracture with a view to soothing the patient, the relief of muscular spasm and rapid absorption of extravasated blood. 2. Passive movements of the joints above and below the fracture (thus effecting internal massage) by which all matting of the soft parts at the seat of the fracture and above the joints is prevented. 3. The development of wasted muscles by the ordinary massage processes" We commend the perusal of this book to those interested in the subject.

EXAMINATION OF THE URINE. (a)

As the author indicates in his preface, this volume naturally falls into two parts. Part I. describes the various chemical and microscopical methods employed in the examination of the urine, while Part II. gives a short summary of the etiology and prominent symptoms of several diseases, and a more detailed account of the leading changes in the urine associated with them. The object of the writer is first to instruct the reader in the methods of urinary examination and then to demonstrate to him how to apply his knowledge as an aid to accurate diagnosis.

We regret the replacement of the term chronic parenchymatous nephritis by subacute glomerular nephritis. Histologically and chronologically, in our opinion, the modern phrase is inaccurate, and even Dr. Ogden, though he holds that the essential lesions are in the glomeruli, admits that there is extensive degeneration, necrosis, and desquamation of the tubular epithelium.

In an interesting description of the elimination of sulphates, and the diseases which disturb the normal proportion of the alkaline and ethereal sulphates, we notice no reference to pernicious anæmia. Other writers attach considerable importance to the marked disproportion of the ethereal sulphates in this obscure affection, as a point in favour of the hypothesis that the initial lesion is intestinal. There is an excellent chapter on the occurrence of carbohydrates in the urine, but most readers will think it rather contradictory to be told in one place that glucose is extracted from its solutions by animal charcoal, and subsequently to be directed to free urine from any turbidity by filtration through animal charcoal before using the saccharometer. All through the book, but especially in this chapter, we feel it a great drawback that only empirical formulæ are given in expressing a chemical reaction. Structural formulæ are more easily understood and remembered by a student with a moderate knowledge of chemistry.

In describing the tests for acetone we notice no reference to an important reaction to which Professor Reynolds some time ago drew attention. He has shown that acetone is able to dissolve the yellow precipitate of mercuric hydrate produced by the intern action of corrosive sublimate and caustic soda. We can fully indorse the author's opinion of the value of Gerhardt's reaction in diabetic urine as a danger signal that coma is threatening, but no mention is made of the possibility that hydroxybutyric acid is the antecedent of aceto-acetic acid.

There are some clerical errors such as "Widal" for "Weidel," "lactic" for "acetic," "urine" for "urea," which can be easily corrected if a subsequent edition be demanded.

(a) "Lectures on the Use of Massage and Early Passive Movements in Recent Fractures, together with the Treatment of Internal Derangement of Knee-joint and the Management of Stiff Joints." By Sir William H. Bennett. K.C.V.O., F.R.C.S., Senior Surgeon to St. George's Hospital. Second Edition. Seventeen Illustrations. Pp. 115. Price 6s. London: Longmans, Green and Co. 1902.

(a) "Clinical Examination of the Urine and Urinary Diagnosis." By J. Bergen Ogden, M.D. Philadelphia: W. B. Saunders and Company. 1900.

In conclusion, our opinion of the value of this book may be briefly expressed by stating that we have not merely dipped into it here and there. We have read it from cover to cover. The type is good, the illustrations are fair, and the clerical errors are not numerous. Taking the book all round we can commend it as a trustworthy up-to-date work on urinary chemistry and diagnosis.

HANDBOOK OF OBSTETRIC NURSING. (*a*)

This handbook for midwives has now reached the fourth edition; in it special attention has been given to the management of labour, and particularly to that of the third stage. Recognising the immense importance of antiseptics in midwifery, the authors have drawn up rules applicable to the antiseptic management of labour both in hospital and private practice. Undoubtedly one of the most essential things for an obstetric nurse is to know the meaning and application of antiseptics. In the second chapter the meaning of blood poisoning in puerperal fever is made clear, and the striking fact is instanced that since the introduction of antiseptics into the large maternity hospitals, the mortality from childbed fever has fallen from 15 per cent. to almost none at all. Antiseptics therefore have almost entirely annihilated puerperal fever.

The list of antiseptic solutions is up-to-date, but the value of formalin as an antiseptic is not recognised. The rules for sterilisation of the hands are excellent. We do not agree with the advice in the management of the second stage of labour, when, on page 119, examinations are recommended to be made "every half-hour" to ascertain if progress is being made. We consider this distinctly meddlesome and unnecessary; each fresh examination undoubtedly adds a fresh risk of infection. More importance should have been attached to abdominal palpation as a means of recognising the presentation and for estimating the progress of labour. What is the advantage of Fig. 25—a malacostron pelvis—to midwives? We make these criticisms in no captious spirit; we congratulate the authors on their useful handbook. It is one of the best for the instruction of midwives. Much scientific detail is omitted; the facts are both practical and essential.

ROSS ON MALARIAL FEVER. (*b*)

The subject-matter dealt with by the author's pen should require no other pen to recommend it.

The work is intended for the use of travellers, sportsmen, soldiers, and residents in malarious places, and so the "fairy-tale of science" which it contains is written in language of every-day life. That it has passed into a ninth edition shows that it has been appreciated by those for whom it was intended.

Having discussed the etiology of the disease, which forms one of the romances of medicine, the author says: "All these are not theories or fancies, but hard facts, won by science at the cost of immense labours carried out by many scientific men during many years." This but feebly expresses the truth, and it is a wonderful tribute to medical science that these hard facts, won at the cost of immense labours during so many years, are freely given away to all and sundry who choose to profit by them.

Within the short compass of sixty-eight pages the whole subject is considered in a brief but thorough manner, so that the causes of the disease being fully understood, the reader may deal with its prevention intelligently, and in emergency even treat it when it occurs in the absence of medical aid. No traveller to malarious districts should start on his journey without having read this book, and thus armed himself with the means of resisting the free scourge of malaria.

The book is issued under the ægis of the Liverpool School of Tropical Medicine, where Dr. Ronald Ross is lecturer and the acknowledged authority on the subject. The type and get-up of the book are all that could be desired, and its price places it within the reach of even a humble migrant.

WALKER'S INTRODUCTION TO DERMATOLOGY. (*a*)

This is the second edition of a book for which we ventured to augur a successful career on its first appearance. It is larger than its predecessor, but is still kept carefully within a manageable compass. Many of the trifling lapses that somewhat marred the first edition have disappeared, and a higher standard of achievement has been reached. At the same time a few points may be criticised. In speaking of the Röntgen ray treatment Dr. Walker alludes simply to a lay worker in a London hospital. There are many competent medical practitioners who have worked in that direction; indeed, Dr. Walker need hardly have left Scotland for authorities. It is too much the tendency, however, for medical men to employ workers outside their own profession, not only in the Röntgen ray but in other branches of work. Nemesis follows in the shape of fresh hordes of irregular practitioners. In this edition, as in the first, the author adheres to his extraordinary classification by which he places pediculosis corporis among the hæmorrhages. He shows certain qualms of conscience by an apologetic introduction to his text. Lapse of time and the necessity of a third edition will probably enable him to review his position in this particular. Dr. Walker takes an advanced position with regard to "psoriasis," which he regards as an extremely dry form of seborrhœa, but he wisely describes the condition separately. The value of this edition is increased by the appearance of some new plates, such as those of the early and later stages of mycosis fungoides, and an excellent one of erythema induratum. The appearance is suggestive of syphilis, from which, however, it can usually be readily differentiated by a consideration of the whole facts of the case. A perusal of this book strengthens the favourable view we took of the first edition. As a handbook for the use of the student or the general practitioner we know of no more handy and accurate guide to an important subject. In future editions it is to be hoped that Dr. Walker will avoid the diffuse dissertations and undigested masses of information that are dear to several well-known writers on dermatology. He brings a wide practical experience to bear upon his subject, and it is somewhat curious to see so clear a writer classify pediculosis corporis among the hæmorrhages. It is with real pleasure we recommend this book to all who wish to have in their possession a concise and easy introduction to the study of diseases of the skin.

FORTHCOMING NEW BOOKS AND NEW EDITIONS.

Messrs. Bailliere, Tindall, and Cox have sent us the following list of new books and new editions to be published by them during the current month:—The fifth edition of Messrs. Rose and Carless's "Manual of Surgery"; the fourth edition of Professor Politzer's text-book of "Diseases of the Ear" (authorised English translation under the author's supervision); the fourth edition of Messrs. Cross and Cole's "Modern Microscopy"; the fourth edition of Dr. Murrell's "Forensic Medicine and Toxicology"; the fourth edition of Dr. Gubb's "Aids to Gynæcology"; the third edition of Dr. Macnaughton Jones's "Practical Points in Gynæcology"; and revised editions of "Aids to Sanitary Science" (by Dr. Allen and Dr. Farrar), of Fleming's "Text-book of Veterinary Surgery" (revised by Professor Macqueen) and of "The Veterinary

---

(*a*) "Handbook of Obstetric Nursing." By Francis W. N. Haultain, M.D., F.R.C.P.Edin., and James Haig Ferguson, M.D. F.R.C.P.Edin. With Frontispiece and 87 Engravings Edinburgh and London: Young J. Pentland. 1902.

(*b*) "Malarial Fever: its Cause, Prevention, and Treatment." By Ronald Ross. Ninth Edition, revised and enlarged. 2s. 6d. Published for the University Press of Liverpool by Longmans, Green and Co. 1902.

(*a*) "An Introduction to Dermatology." Norman Walker, M.D., Assistant Skin Physician, Edinburgh University. Second Edition. John Wright and Co., Bristol. 1902. Price 9s. 6d. nett.

Pharmacopœia," by Dr. G. Gresswell. Also the following new works: "Errors of Refraction," by Mr. Ernest Clarke, F.R.C.S.; a monograph on "Pulmonary Consumption," by Dr. Arthur Latham (winner of the King's prize of £500); a monograph on "Anæsthetics," by Dr. Blumfeld; "Essays on Operative Surgery," by the late Sir Wm. Stokes; and "The Theory and Practice of Infant Feeding," by Dr. Chaplin.

Mr. H. K. Lewis sends us the following list of new works and new editions: "Cancer of the Uterus: a Clinical Monograph on its Diagnosis and Treatment," by A. H. N. Lewers. "Handbook of the Pathology of the Skin: being an Introduction to the Histology, Pathology, and Bacteriology of the Skin, with special reference to Technique," by J. M. H. MacLeod, Assistant in the Bacteriological Department, Charing Cross Hospital. A new (third) edition of "Diseases of the Skin: their Description, Pathology, Diagnosis, and Treatment," by H. Radcliffe-Crocker; the second edition of "Hygiene and Public Health," by L. C. Parkes and H. R. Kenwood; and a new edition of "Ophthalmic Practice," by Charles Higgens, revised with the assistance of A. W. Ormond, ophthalmic clinical assistant, Guy's Hospital.

Medical News.

Death under Chloroform.

A man, sixty-two years of age, died at the Wrexham Infirmary a few days since while chloroform was being administered for the purpose of an exploratory operation. "The usual examination" was made before commencing the administration of the drug, and "the usual treatment" was resorted to when the heart had ceased to beat, but no mention is made of the method of administration, nor of the quantity of chloroform used—the only points worth inquiring into in the event of a catastrophe.

Presentation to a Medical Man.

Dr. H. S. Morrison, medical officer of Aghadowey, has been presented with a purse of sovereigns and an illuminated address; and Mrs. Morrison received a service of silver plate. The presentation was given by the *employes* of the Aghadowey Creamery to Dr. H. S. Morrison, as president of the Aghadowey Creamery and chairman of its executive committee. We congratulate the doctor on this deserved recognition of his ability and usefulness in one of the most progressive districts in Ireland.

Malaria at Ismailia.

It is stated that the Chairman of the Liverpool School of Tropical Medicine has been requested to co-operate in a concerted effort to cope with the prevalence of malaria in Ismailia. Major Ross has consequently been instructed to commence operations against the mosquitoes during the present month.

Memorial to Professor Virchow.

A meeting was held at Berlin last week, under the presidency of Professor Waldeyer, to discuss a scheme for raising a memorial to perpetuate the life and work of the late Professor Virchow. The memorial will probably take the double form of a statue and a scholarship for original research.

Gynæcological Congress at Rome.

The Fourth Congress of Gynæcology was held at Rome last week, at which assisted a large number of members recruited from all parts of the world, although England appears to have been represented only by two gynæcologists of eminence.

Ecclesiastical Hygiene.

It is stated that a petition has been presented to the Pope asking that plenary indulgence shall be granted to all priests and monks who shall wash themselves daily, with an extra partial indulgence to those who shall have shaved regularly at least three times a week during a specified period. This is evidently aimed at certain Italian monks and seminarists who still cling to the "odour of sanctity," and among whom soap, the hair-brush, and the looking-glass are worldly luxuries excluded by rule. They exhibit, in fact, what Lord Palmerston once called the *esprit de corps*.

Small-pox in Barbadoes.

The outbreak of small-pox in Barbadoes continues to spread, and the attempt to isolate the victims of the disease has, on several occasions, led to riots. The type of the disease is very mild, and the proportion of fatal cases has been extraordinarily low.

A Public Vaccinator's Dilemma.

Dr. Jones, one of the Public Vaccinators for Southwark, sent in a bill for revaccinations including an item of £160 in respect of the *employes* of certain factories, many of whom did not reside in the district. This sum has been disallowed by the guardians on the ground that their authority was not obtained, but Dr. Jones claims that the necessary authority was given him by the Local Government Board.

A Nurse's Claim for Wrongful Dismissal.

An action was tried at the Barnstaple County Court a few days since in which a trained nurse claimed for wrongful dismissal. It seems that while in charge of a patient the plaintiff lost her purse, and as it could not be found she applied to a constable for advice. She was thereupon summarily discharged, and the judge held that this act could not be justified, and gave judgment for the plaintiff, observing that it was a gross case, and had it been in his power he would have awarded damages.

The R.C.S.E. Charter.

The claim of nine members of the Council of the Royal College of Surgeons of England to the franchise on the strength of the charter given to the College by Henry VIII. has been disallowed by the Revising Barrister, and notice of appeal has been given.

Royal Army Medical Corps.

An Army Order dated September 1st, just issued, contains a Royal Warrant relating to the medical officers of the Household troops. It sets forth that commissions as surgeon-lieutenants in the Household Cavalry shall be given, on the nomination of the titular colonels of the regiments, to persons approved by the Secretary of State. Lieutenants and captains of the R.A.M.C. attached to regiments of the Household Cavalry at the date of the Warrant may, on the nomination of the titular colonels of the regiment, be transferred thereto in the rank of surgeon-lieutenant and surgeon-captain respectively. A major or lieutenant-colonel of the R.A.M.C. may, on the nomination of the titular colonel of the regiment, be transferred from his corps into the rank of surgeon-major or surgeon-lieutenant colonel respectively in one of the regiments of Foot Guards.

Galway County Hospital.—The Nursing Question.

At the usual meeting of the Board of Management of the Galway County Hospital the nursing question was considered. Mr. Leonard, secretary to the hospital, brought under notice a draft copy of rules suggested by the medical staff at a meeting held on July 6th last. The salient feature of the scheme is the amalgamation, for the purposes of teaching, of the material of the fever hospital, the union hospital, and the county hospital. After a protracted discussion it was finally decided that a committee of five members of the board of management meet and confer with the medical staff as to some feasible scheme in reference to the proposed training school, and to report results to the Board in the first week of December.

Dublin Death-rate.

The deaths registered in the Dublin registration area for the week ending Saturday, September 13th, 1902, represent an annual rate of mortality of 19·5 in every 1,000 of the population. Diseases of the nervous system caused twelve deaths; of the respiratory system, fourteen deaths; and of the circulatory system, seventeen deaths. Sixty-two infants died during the week, of whom forty-eight were under twelve months old. Within the city the death rates of the following areas were as follows:—Blackhall Place, 29·6 a 1,000; South Earl Street, 21·8 a 1,000; Grand Canal Street, 23·9 a 1,000; and in the Cattle Street district, 30·5 a 1,000.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Original Articles or **Letters** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Hertford.—If the case be investigated with an unbiassed mind, it will probably be found to have originated in a slight misunderstanding. We strongly advise you against the proposed action.

Dr. G. H. Evans (San Francisco).—Letter to hand will be considered.

Nurse Armstrong.—We regret that we have not the necessary information to enable us to answer your question. We recommend you to apply to a nursing journal, such as *The Hospital*, or *Nursing Notes*, as they may possibly be able to tell you what you want to know.

A **correspondent** writes: I note that a pharmacy has recently been opened in the W.C. district, the proprietor of which rejoices in the name of Cofman, surely a peculiarly significant name for a retail chemist. A "Cofman's Remedy for Consumption" ought to be a success with the gogo public.

DEAR FAT.

A **subscriber**, in discussing the benefits to be derived from the Weir-Mitchell treatment in neurasthenia, relates the case of a young Colonial who underwent a six-weeks' course of the treatment in a well-known institution in London. When he left he found he had gained a little over three pounds in weight, and on dividing this into the sum he had paid for the treatment he found that it worked out at something like twenty-five shillings an ounce. Even Colonial fat, he thought, was dear at the price.

MYSTERIOUS DEATH OF A MEDICAL PASSENGER.

Dr. William Madde, a passenger on board the ss. *Madeirense*, now lying in Penarth Harbour, was found dead in his cabin a few days since, and it is surmised that he had succumbed to an overdose of laudanum.

PREACHERS AND PUBLIC HEALTH.

A **meeting** was held last week at the Mansion House, York, under the auspices of the Church Sanitary Association. Among the letters of regret at inability to be present was one from Mr. J. G Butcher, M.P., K.C., who expressed the opinion that it was of the utmost public importance that the Church had actively taken up so vital a question as the health of the people, and he wished the Church Sanitary Association every success in its efforts to bring about much-needed reforms by dispelling ignorance and stimulating public interest in sanitary matters. The Rev. F. Lawrence, honorary secretary, said it was desirable that at every examination of candidates for Holy Orders one paper should be on personal and domestic hygiene, to enable the clergy to co-operate with the sanitary authorities.

GOOD CROPS BRING PROSPERITY.

A **Georgia** farmer made £25 from an acre of watermelons, and the nearest doctor made £50 from the same acre.

MURDER STATISTICS.

While in London, with its six million inhabitants, there are, on the average, only about twenty murders annually, the United States can boast of no less than 10,000. If the same proportion obtained in London there would be 900 or 1,000. It is a significant fact that out of 145 murders in five years only twenty-three of the criminals were convicted, and not one executed. "So much hemp grown so little used!"

Appointments.

Baxter, Alexander Kidd, M.B., Ch.B.Edin., House Surgeon to Tiverton Infirmary and Dispensary, Devonshire.

Body, H. M., M.R.C.S., L.S.A., Medical Officer of Health of Crediton (Devon).

Holmes-Merrick, F. R., M.D.Dubl., Medical Officer of Health for the Rural District of Basingstoke.

Muir, D. C., M.D.Glasg., Medical Officer of Health to the Abertillery Urban District Council.

Nesbitt, R., L.R.C.P. and L.M.Irel., Medical Officer of Health to the Sutton in Ashfield Urban District Council.

Raby, L., M.D.Durh., Medical Officer for the Second District of the Devizes (Wilts) Union.

Robson, Henry Naunton, L.R.C.P.Lond., M.R.C.S., House Surgeon at the General Hospital, Stroud, Gloucestershire.

Sandiland, Digby S., M.R.C.S., L.R.C.P.Lond., Senior House Surgeon to the West Ham and East London Hospital, E.

Vacancies.

Assistant Pathologist and Demonstrator of Pathology at St. Thomas's Hospital and Medical School, London. Salary £250 per annum. Applications to the Treasurer's Clerk.

Brompton.—Assistant Resident Medical Officer, Hospital for Consumption and Diseases of the Chest. Salary £100 per annum, with board and residence. Applications to the Secretary.

Cancer Hospital, London.—Pathologist. Salary £250 per annum, Applications to the Secretary at the Hospital, Fulham Road. S.W.

Children's Hospital, Forest House, Nottingham.—House Surgeon. Salary £100 per annum, with board and residence. Applications to the Secretary, Mr. A. F. Kirby, St. Peter's Church Walk, Nottingham.

Cornwall County Asylum, Bodmin.—Junior Assistant Medical Officer. Salary £130, with board, furnished apartments, laundry, &c. Applications to the Medical Superintendent.

County Asylum, Chester.—Third Assistant Medical Officer. Salary £160 per annum, with board (no liquors), lodging, and washing. Applications to Dr. Lawrence, County Asylum, Chester.

East Sussex New Lunatic Asylum.—Appointment of Medical Superintendent. Salary £900 a year, with unfurnished house (the Committee paying rates and taxes), electric light as fitted. water-supply, coals. vegetables, milk, and washing. Applications to Reginald Blaker, Clerk of the Visiting Committee, 211, High Street, Lewes.

London County Asylum.—Junior Assistant Medical Officer. Salary £150 per annum, with board, apartments, and washing. Age under 30 years. Forms of application of the Clerk to the Asylum's Committee, 6, Waterloo Place, London. (See advt.)

Monmouthshire Asylum, Abergavenny.—Junior Assistant Medical Officer (Male). Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Roxburgh District Asylum, Melrose, N.B.—Assistant Medical Officer. Salary £140 per annum, with board, rooms, and washing. Applications to the Medical Superintendent.

The General Infirmary at Gloucester and the Gloucestershire Eye Institution.—House Surgeoncy. Salary £100 per annum, with board, lodging, and washing. Applications to the Secretary.

The Metropolitan Asylums Board.—Male Assistant Medical Officers. Salary £180 per annum, with board, lodging, attendance, and washing. Applications to Clerk, Metropolitan Asylums Board, Embankment, E.C.

Westminster Hospital.—Assistant Pathologist and Curator of the Museum. Salary 100 guineas a year. Applications to the Secretary by October 7th.

Urban District Council of Withington.—Hospital for Infectious Diseases.—Resident Medical Officer. Salary £120 per annum, with board, apartments, and washing at the hospital. Applications to Albert Roberts, Clerk, Town Hall, West Didsbury.

West Riding Asylum, Wadsley, near Sheffield.—Fifth Assistant Medical Officer. Salary £140, with board, &c. Applications immediately to the Medical Superintendent.

Births.

Cleveland.—On Sept. 18th, at 8, Thorpe Mansions, Norwich, the wife of Arthur J. Cleveland, M D.Lond., M.R.C.P., of a son.

Mallam.—On Sept. 15th, at Holywell Street, Oxford, the wife of Ernest Mallam, B.M., B.Ch.Oxon., of a son.

Voelcker.—On Sept. 17th, at 101, Harley Street, London, W., the wife of Arthur Francis Voelcker, M.D., F.R.C.P., of a son.

Marriages.

Connell—Sealy.—On Sept. 17th, at St. Mary Magdalene's, St. Leonards-on-Sea, Arthur Mayers Connell, F.R.C.S.E., of Sheffield, Yorkshire, to Emily Mary, second daughter of John Sealy, M.D., of Hill View, Barbados, W. Indies.

Dickie—Mitchell.—On Sept. 16th, at St. Mary's Episcopal Church, Glasgow, William Stewart Dickie, M.R.C.S, Middlesbrough, to Jean Kennedy, daughter of John Oswald Mitchell, LL.D., 7, Huntly Gardens, Glasgow.

Gullan-Goodwin.—On Sept. 17th, at St. Saviour's Church, Oxton, Birkenhead, Archibald Gordon Gullan, M.D.Lond., M.R.C.P., F.R.C.S., 37, Rodney Street, Liverpool second son of the late Archibald Black Gullan, of Swansea, to Agnes, third daughter of Ambrose E. Goodwin, of Oxton.

Stephenson—Johnson.—On Sept. 16th, at St. Barnabas's Church, Kensington, W. A. Stephenson, M.R.C.S.Eng., L.R.C.P.Lond., to Sarah Louise Johnson, both of West Haddon. No cards.

Winter—Hallett.—On Sept. 17th, at All Saints' Church, Penarth, G. Mitchell Winter, L.R.C.P., M.R.C.S., D.P.H., of Torquay, to Mildred Marion, elder daughter of George Hallett, of Crauford, Penarth.

Deaths.

Blacker.—On Sept. 17th, at 16, West Halkin Street, S.W., Arthur Barry Blacker, M.D., son of the late Rev. Maxwell Blacker, aged 40.

Field.—On Sept. 15th, at Quisisana, Benson, Oxon, Alfred George Field, F.R.C.S.Eng., aged 82.

Cockell.—On Sept. 18th, at 268, Dalston Lane, Hackney, Frederick Edgar Cockell, M.R.C.S.Eng., L.M., aged 72 years.

The Medical Press and Circular.

VOL. CXXV. WEDNESDAY, OCTOBER 1, 1902. No. 14.

Original Communications.

COCCYGODYNIA.

By E. NOBLE SMITH, F.R.C.S.EDIN., &c.,

Senior Surgeon to the City Orthopædic Hospital, London.

THE lowest extremity of the human spine is occasionally the seat of much trouble arising either from accident or disease. The bone which forms this appendix, the coccyx, derives its name from its supposed resemblance to a cuckoo's beak. (*a*) It forms a rudimentary tail, and, like most rudimentary parts, serves no useful purpose in the human economy.

The late Mr. Hilton (*b*) called attention to the fact that the coccyx is liberally supplied with nerves of sensation in intimate structural communication with the anterior or sacral nerves, which again join the sympathetic plexus of nerves in the pelvis, and thence proceed to the uterus and ovaries, and that the gluteus maximus muscle is attached to it. Luschka (*c*) described a small gland freely supplied with nerves situated at the anterior surface of the end of the coccyx, intimately connected with the *ganglion impar* of the sympathetic nerve, and with branches of the middle sacral artery.

The word "coccyodynia" was invented by the late Sir James Y. Simpson, of Edinburgh, to describe a painful affection of the coccyx. The word has more recently been written coccygodynia as a more correct philological interpretation of the term "pain in the os coccygis" or coccyx bone. Sir James (then Dr.) Simpson wrote (*d*) regarding the name: "Besides that it is sufficiently terse to be easy of use, the designation presents this great advantage, that it involves no pathological theory as to the nature of the affection, but simply expresses its most striking symptom." In referring to the various diseases which may affect the coccyx, Simpson further remarks: "If more attention were directed to the pathological and anatomical history of this organ than has hitherto been accorded to it, it would probably be found to be subject to diseases and disorders such as have hardly been even suspected."

Dr. J. C. Nott, of New York, wrote to Simpson pointing out that he (Nott) had fifteen years previously described similar cases in the *New Orleans Medical Journal*, and Simpson published this letter in the *Medical Times and Gazette* of March, 1861.

But even previous to Nott's communication the subject had received attention. We find in James Blundell's "Obstetric Medicine," (*e*) a reference to coccygeal trouble. He states that inflammation of the sacro-coccygeal joint is often a cause, and this may be "wholly unconnected with pregnancy or parturition." One of his patients had adopted the expedient of sitting on the framework of a chair from which the cane seat had been removed. He also refers to suppuration of the joint in scrofulous subjects, and adds:—"I may remark, by way of suggestion, that you might perhaps remove the os coccygis altogether; for this bone does not appear to be of any very great importance in the skeleton."

As regards records of trouble from injury to the coccyx, we may go back to a much earlier period. Simpson remarks that Smetius, a professor of medicine in the University of Heidelberg, records in his diary:—"1588, October 27. My wife has fallen backwards, and so injured the coccygeal bone that she cannot sit without great pain, nor can she empty the bowel or the bladder, or cough, without much distress;" and other ancient records of cases are mentioned by Simpson and others.

Coccygodynia is probably always caused by some distinct disorder either of the bone itself or its immediate surroundings. The morbid condition may originate in rectal or anal troubles, or be reflex from some pelvic mischief, or it may more probably come from disease of the bone or chronic neuritis arising from previous injury.

Coccygodynia is sometimes associated with hysteria, and the relief of the local trouble is generally followed by relief of the other symptoms.

The coccyx may be injured by direct blows, and especially by falls in the sitting posture. Sitting down suddenly upon a small object which impinges upon this part is one of the most frequent causes. The bone may even be fractured, and Hamilton (*a*) refers to two cases recorded by Cloquet, (*b*) one produced by a kick and the other by a fall. In the latter case the coccyx became carious and was gradually exfoliated.

An injury may be caused in parturition. Dr. Robert Barnes, (*c*) in referring to this fact, remarks that he has known several aggravated cases follow labour, and he had no doubt "that the joint received injury during the passage of the child's head." Ankylosis may follow injury of any kind, and Dr. Barnes notes that the ankylosis is likely to give way during labour, and even where there is no ankylosis the anterior ligaments of the sacro-coccygeal joint may be ruptured and "inflammation is very apt to be set up." Simpson knew abscess to follow such an injury. Barnes further states that the disease occurs where no history of injury is present, and quite unconnected with parturition, as, for instance, in the unmarried. Ramsbotham (*d*) states that ankylosis often occurs in women who have been accustomed to sit the principal part of the day, "as is the case with milliners."

If an injury has been recently received there may be acute inflammation of the part. The coccyx may have been violently bent forwards, severely spraining the sacro-coccygeal joint, rupturing its ligaments or fracturing a portion of the bone. Upon examination, under such circumstances, the surgeon may find the bone displaced forwards, pressing on the rectum, or it may have regained its natural position.

Examination.—The surgeon should pass his forefinger

(*a*) It has also been called the huckle or knuckle bone.

(*b*) "Rest and Pain," by John Hilton, F.R.S. Second Edition. London, 1880.

(*c*) Virchow's "Archiv," 1860 ("Die Steissdruse des Menschen").

(*d*) "Clinical Lectures on the Diseases of Women." Lecture xvii. *Med. Times and Gaz.*, July 2nd, 1859.

(*e*) Edition revised by A. Cooper Lee and Nathaniel Rogers. London, 1840.

(*a*) "Fractures and Dislocations."

(*b*) Cloquet, art. "Bassein" of *Dict.*, vol. iii.

(*c*) *Op. cit.*

(*d*) "Principles and Practice of Obstetric Medicine and Surgery." By Francis Ramsbotham, M.D. Third Edition. London. 1851.

into the rectum and grasp the coccyx between it and the thumb placed externally. The condition of the bone can then be fairly accurately determined. Its position, mobility, &c., can be felt, and the effect upon the patient of pressure and movement of the bone can be determined.

Treatment.—If the parts are hot, swollen, and extremely painful, it may be desirable to apply hot fomentations, or even leeches, and a morphia suppository is very useful in subduing pain. Rest in bed is essential, and a simple purge should generally be administered. The bowels should be kept slightly relaxed for several days, until the acute symptoms have subsided.

If the bone is displaced it can, as a rule, be easily reduced to its natural position, but whether it will stay there is another matter. Complete dislocation may, however, resist all efforts at reduction without open operation.

Energetic treatment at this early stage of injury may result in perfect relief after a few days' or a week's rest and by making the patient use a horseshoe air-cushion when sitting, for a few weeks, all future trouble may be removed.

Chronic Cases.—It is the chronic cases which chiefly require our consideration, treatment of the acute being, as I have shown, sufficiently simple. In these chronic cases the symptoms are often obscure and frequently involve a general disturbance of the nervous system. Care in diagnosis is required. Pain may be localised by the patient at the exact seat of trouble, or may be more or less remote.

Spinal neuralgia, more often felt in the region of the sacrum or higher in the spine; pelvic troubles, such as a sense of "bearing down"; constipation from direct pressure of the bone on the rectum; irritability of the bladder; a sense of general discomfort in the pelvis or rectum, and other symptoms, sometimes obscure, may be present, and often the bone itself is not thought to be the exact seat of trouble until it is manipulated by the surgeon.

There is generally a difficulty in sitting down, and patients complain that they are never comfortable when sitting evenly on a chair. A tendency to sit sideways, inability to sit up straight in bed, and pain or straining during action of the bowels, are common symptoms.

Various remedies have been advised. Rest in bed, emollient and sedative local applications, and other measures to allay pain have been used, and doubtless such remedies have their value. If the bone is displaced and can be restored to its natural position and kept there, the patient may thus be relieved or even cured, but more often such remedies are only partial or temporary in their effects.

Subcutaneous section of the tissues close round the bone, with the object of cutting off its nerve supply, has been performed, but this is not a scientific procedure; it may relieve pain in the bone itself, but does not remove the displacement, or disease, such as caries, if these conditions be present Moreover, if the bone is pressing on the rectum, the operation does nothing to relieve that pressure. Dr. Thomas (a) resorted to subcutaneous section once. He found it fail entirely in giving relief. Sir James Simpson was obliged to remove part of the coccyx after failing to give relief by "separation of the coccyx from all the surrounding muscles, tendons and ligaments, which was done subcutaneously with a tenotomy knife."

Excision of the bone is the only certain cure, and if the palliative measures or replacement of a dislocated bone are not soon successful, an operation should not be delayed. It is hardly necessary here to describe the details of procedure, the bone being removed through a longitudinal posterior incision.

This is a safe operation, but care is required to avoid any injury to the rectum, which lies very close to the anterior surface of the bone.

In the following record of cases several methods of treatment are described, and it will not be difficult for the reader to judge which is best.

The late Mr. John Hilton described some cases which he treated upon the *rest* principle.

CASE I.—A young woman had fallen, ten months previously, upon the corner of a chair and had thus injured the coccyx. She had much pain when the bowels acted, or when she attempted to rise from a seat. She could walk but slowly and had great pain in going up stairs or in sitting down.

The coccyx was bent forwards at almost right angles with the last bone of the sacrum, and thus pressed upon the rectum. The joint between the two bones was swollen and very painful when the end of the bone was pushed upwards, and pressure upon any part of the bone hurt the patient.

The *treatment* was very tedious and was as follows. For eighteen days the patient had to lie down *as much as possible* and take medicine to keep the contents of the bowel soft. At the end of this time she was "*much relieved.*" About two months later she suffered "*no important inconvenience unless* she happened to sit abruptly upon a hard flat surface"; "the pointed end of the coccyx *annoyed the rectum somewhat,* but *she was getting accustomed to that*"!

The following year she is reported as "*remaining* well." (The italics are mine.) We may suppose that she had got quite accustomed to the point of the coccyx pressing on the rectum, or is it not more likely that she had learned to put up with it, as no other remedy seems to have been suggested? It was not good surgery to leave the bone in its displaced position.

Another patient, a girl, æt. 16, was quite well up to the time of the accident which injured the coccyx, but "since that time—about six months—she had suffered so much from pain, constipated bowels, and loss of appetite, as to render her general health anything but good."

The treatment was absolute recumbency for eight weeks; after that, carefully controlled exercise, part of the time being spent at the seaside. Mr. Hilton further stated that the patient "ultimately got quite well," except a slight disposition to be constipated.

The first case cannot be considered as perfectly cured, and the second hardly so, although both patients were subjected to prolonged recumbency and medicinal treatment.

Dr. Roeser (a) described a case in which there was lateral dislocation of the coccyx. It occurred in a very stout woman, who in jumping off a table fell astride a chair. Very severe symptoms followed. Besides severe local pain, for which she had to take to her bed, dragging painful sensations extended from the nape of the neck down to the ends of her fingers, which were numbed. Upon reduction, by passing a finger into the rectum and making traction, all nerve symptoms were removed and the patient was cured.

Skey recorded the case (b) of a young woman, æt. 20, who had had a fall three weeks before he saw her. The coccyx was found to be "thrown forwards at a right angle with the sacrum, the point projecting against the rectum." By pressure through the bowel it could be replaced, but upon removal of the finger it immediately returned to its former position.

Mr. Skey designed a small metal spring which he placed in the rectum, but the pain produced was so severe, and the difficulty of fixing the spring so great, that he had to give it up. He then cut down on the bone and passed a silver wire round it, and attached that to a back splint; the wire broke and he substituted strong thread. This treatment, as may be easily realised, was most painful and had to be relinquished, and after a few days "the bone returned to its abnormal relation with the sacrum."

Dr. A. P. Shands, of Washington, U.S.A., describes a very interesting and instructive case. The patient was a lady, æt. 22. Her family medical history was good, and she was perfectly healthy herself until the age of sixteen, when she had diphtheria, after which she was never strong. Two years after the diphtheria she was examined for symptoms thought to be those of disease of the vertebral column. She had been in an extremely nervous condition during this two years, never free from pain in some part of her body, and often in many places at the same time, sometimes in the stomach, at others in the abdomen, and often in the pelvic region. She suffered much from constipation and occasionally from diarrhœa. Headaches and insomnia would occur and continue for months at a time. It was even thought that she might have cancer of the stomach. Sleeplessness, low spirits, hysterical symptoms of various kinds, and a cough, incessant at times for four hours or longer, were some of the more prominent symptoms In bed she would lie on one side, with her thighs and knees flexed as much as possible, the knees pressing on the abdomen. Upon examination of the spine, no *definite* symptoms could be found. The other symptoms continued, and eighteen months later the chief point of suffering seemed to be the coccyx. Without dilating further upon the case, it may be said that the coccyx was ultimately excised. There was then found to be a new bony growth at the extreme end of the bone, a quarter of an inch long, with a carious cavity, another growth at the side of the bone half the size of that of the extremity. At the upper end of the bone next the sacrum, was found a carious cavity about the size of a pea. The acute symptoms were entirely relieved by the operation, but the health of the patient had become so undermined by the constant pain she had suffered, that she succumbed four months later from emaciation.

(a) *Brit. and F. Med. Chir. Review*, 1857, ii., 544.

(b) *Lancet*, October 5th, 1861.

Dr. Shands suggested that all the symptoms arose from the disease in the coccyx.

This paper was read before the American Orthopædic Association, June, 1901, and is reproduced in the "Transactions" of that association.

I will now describe some of the cases which I have met with.

Miss H., æt. 15.—November 16th, 1888. This patient was sent to me by Mr. Reginald Harrison. Two years previously the patient had fallen in the sitting position, a chair having been taken away by some one. A week later severe pain was complained of in the region of the coccyx, and this had gradually got worse. The coccyx was bent forwards, and was pressing on the bowel. The part was too painful to permit any interference without an anæsthetic. Under chloroform I passed my finger into the bowel, and with some difficulty pressed the coccyx into its proper position. The patient used a horseshoe air-cushion when sitting for some weeks, and was perfectly cured.

Miss C —February 27th, 1894. The patient felt pain for some months in the neighbourhood of the coccyx in sitting down and especially when leaning back. I found exostosis at the end of the coccyx, of which I recommended excision, and the operation was performed. I believe the result was perfectly satisfactory.

Miss N., æt. 17.—March 5th, 1897. She had felt pain in the region of the coccyx since the previous November. There was no known cause, but she had been riding a bicycle, and might have injured the coccyx by pressure. The pain was getting gradually worse; it affected her when she sat down, but not when standing.

The coccyx was displaced forwards. I replaced it per rectum, which immediately gave her relief. There was a tendency to redisplacement, but after several repetitions of the manual readjustment the parts recovered their normal condition, and the patient remained well.

[Since the above was written this patient has returned to consult me again (August, 1902), pain and discomfort having returned and general nervous symptoms having supervened. I now propose to remove the bone.]

Miss K., æt. 25, consulted me in April, 1899, in consequence of constant pain in the region of the coccyx. Two and a-half years previously she had hurt the lower part of the spine by falling down in a sitting position on the deck of a steamer. She felt pain for several months after this accident, but gradually got better. A year later she again injured the lower end of her spine. Getting off a bicycle quickly, she got caught on the point of the saddle. The symptoms were the same as after the previous injury, but much more severe. She could not sit at all for many days. One month later she was advised to have the part operated upon. Subsequently she went under other treatment, without any good resulting. I found the coccyx bent forwards, pressing on the bowel; it was extremely painful at the sacro-coccygeal joint. I removed the coccyx, through a linear incision, the wound was healed four days later, and the result has been excellent. With the exception of some slight attacks of neuralgia in the region of the part during the first few weeks after operation, no pain has been felt since, and she now (May, 1902) remains quite well.

Mrs. F., æt 42.—1897. About ten years ago this patient fell down stairs, striking the end of her spine on the edge of one of the steps. A child was born to her three months later, after which she suffered pain in the whole back. This pain became very severe, principally in the lumbar and cervical regions. Plasters of various kinds were applied. The last treatment employed was massage, which had to be given up because it only increased the pain. The whole nervous system seems to have suffered; pain was described as very severe in the head, with a "buzzing sensation," especially on the left side, "twitching of the eyes and head, left leg very weak." She suffered much from insomnia. For the last year she had not been able to sit evenly. I found the coccyx bent forwards and pressing upon the rectum, and upon examination (per rectum) I could feel a depression at the lower end of the sacrum adjoining the coccyx. Upon movement of the coccyx great pain was produced, which, however, soon subsided. The coccyx and the lower extremity of the sacrum were removed. The patient made a rapid recovery, and all the symptoms described above disappeared.

Mrs. B., æt. 26.—October, 1901. This lady had suffered for many years from aching in the pelvic region; she could not sit down evenly, and when she attempted to sit up in bed the pain was so great she was obliged to turn on one side. Mrs. B had long suffered from violent spasms in the legs on first going to sleep. Her husband stated that this symptom occurred almost every night. A year previous to her visit to me these symptoms had become so acute, and the general health of the patient was so much affected, that further medical advice was obtained, and as a result the uterus was "curetted," and one ovary, it was said, was "*replaced.*" This operation, or the rest it necessitated, seemed to give relief. This relief, however, was only temporary, for the pain soon recurred in the back, especially in the lumbar and sacral regions, and abdomen, with a sense of severe dragging somewhere in the pelvic region. The patient became highly nervous, emaciated and depressed, but there was no difficulty with the action of the bowels and no irritability of the bladder.

Upon examination per vaginam, I found the uterus and ovaries apparently normal and free from tenderness, but upon passing my finger backwards and pressing on the rectum and coccyx, the patient at once complained of acute pain. Upon examination per rectum and upon pressure from without, sufficient to move the coccyx, great pain was produced. Notwithstanding the general nervous and sensitive condition of the patient, there was no hysterical element in this case. No part of the body was sensitive to pressure but the coccyx.

Considering the long continuance of the patient's sufferings, I thought it was useless to try palliative measures, so I recommended excision. On October 26th, 1901, I operated and excised the bone. The wound healed up rapidly, and nine days later the patient commenced to walk about, feeling quite relieved from the former symptoms. She rapidly gained strength, and up to the present time (May, 1902) she has remained absolutely free from all her previous troubles and in every respect well, a condition she had not experienced for many years.

Mrs. W., æt. 38, had been delicate for a long time. She was an interesting patient from having suffered from bubonic plague some years previously in India. It was uncertain when her coccygeal symptoms commenced, because she had suffered from constipation and from hæmorrhoids for years. Neuralgia in the region of the coccyx was her greatest trouble, and of this she had had very violent attacks at intervals of a few weeks or longer. Upon examination per rectum, I found the sphincters very tight. The coccyx was painful upon pressure both externally and internally. I advised that in the first place a free dilatation of the rectum should be carried out. This I did under an anæsthetic, and as soon as the patient recovered from the shock of the operation, she felt hardly any of her previous pain, and a week later she was perfectly relieved not only from the coccygodynia, but also from all other symptoms of pain and irritation in the locality. The hæmorrhoids also ceased to trouble her, and up to now (May, 1902) this patient has remained free from these troubles.

Mrs. N., æt. 42, consulted me in March, 1901. She gave the following account of her case. Five years previous, a few days after straining herself by lifting some heavy furniture, she felt a sudden "crack" in the sacral region. This was accompanied with so much pain in movement of the legs that she had to rest entirely. She was obliged to rest in bed for three weeks, after which she began to get about with difficulty; she gradually got better, but was subject to a continued feeling of discomfort and to periodical attacks of pain and irritation in the region of the coccyx. Spasms in the legs, "jumping," were very frequent at night, and she never could rest comfortably in bed. Upon a thorough examination no symptoms of uterine, bladder, or other organic or functional disorder, except those associated with the coccyx and produced by pressure, could be found. I removed the coccyx and all her trouble disappeared. She remained well in May, 1902.

I have operated, by removing the bone, upon two cases quite recently, and so far they promise to be equally satisfactory.

The most remarkable fact connected with removal of the coccyx is in no instance has the patient experienced any weakness or other defect from the loss of the bone. The functions of the rectum and anus have been in no way interfered with. In fact, patients have described their condition as absolutely satisfactory in every particular.

Queen Anne Street, London.

Paris Clinical Lectures.

TRAUMATIC SCARLATINA.

By DR. R. DE BOVIS,

Professor at the School of Medicine of Rheims.

(Continued from page 323).

As we have just seen, the clinical aspect of surgical scarlatina, except in a few minor points which remain to be discussed, is exactly that of ordinary scarlatina. It is, therefore, natural for us to admit the identity of the two complaints.

If, however, we examine the cases in detail, we find several with rather abnormal peculiarities for scarlatina. We are no longer astonished at the objections raised by Hoffa, Brunner, Strubell, &c. This last one indeed admits only two cases of traumatic scarlatina—his case and that of Leube; all the others are alleged to be erythema, due either to vasomotor troubles, intoxications, or septicæmia. Certainly, mistakes are easily made, and they are perhaps numerous, but they generally appear to be avoidable. That all the authors except two should be mistaken appears to us unlikely.

Independently of this argument, I am enabled to bring forward direct proofs in favour of the existence of surgical scarlatina. We need not insist upon the old adage *Non bis in idem*, in other words, that a patient already a prey to an infectious complaint, does not contract a second. There are exceptions to this rule, and without seeking far, we have the example of scarlatina and diphtheria, so often co-existent in the same subject, while influenza, pneumonia, and mumps are observed almost daily in the care of the wounded. Moreover, the wounded do not fall into the category of "infected" patients, merely because they have a suppurating lesion; they are merely "febriles."

The direct proofs which we can bring forward in favour of the reality of traumatic scarlatina are of four kinds: bacteriological, experimental, epidemiological, and clinical.

The bacteriological proofs have, it is true, but a limited value, since the specific microbe of scarlatina has yet to be discovered. Many facts, however, seem to point to the streptococcus. In 1828, Büdeler admitted that scarlatina might follow erysipelas; Lasch Hertzka, Triwousse, Sörensen, and Patin made the same statement. In two cases, on the contrary, it is traumatic scarlatina followed by erysipelas. A statement by Mr. Solly is equally in favour of these associations:—"Every time," he says, "that I observe a surgical case presenting grave phlegmonous complications, I am sure to observe either a case of erysipelas or scarlatina attacking the inhabitants of the house." At the present day MM. Babes, Volkovitch, and Baginski are inclined to consider the streptococcus as the pathogenic agent of scarlatina. The last named has constantly found the streptococcus in scarlatinal angina at the commencement, and in the ventricular blood of subjects who have died within the first forty-eight hours of the attack.

Moreover, in the rare cases of surgical scarlatina in which a bacteriological examination was made (Strubell, Brunner, d'Espine, and de Marignac), it is also the streptococcus or a very similar microbe which has been noted.

The data furnished by experimental work concern inoculation of scarlatina, which is a genuine surgical scarlatina. Till last year there was a great scarcity of cases of this kind. In the classic treatises, indeed, only the experiments of Stoll, Petit-Radel and Leroy d'Etiolles are mentioned. These observers experimented on themselves and obtained, all except Stoll, negative results. With the aid of Ashmead and Stickler, two American physicians, our knowledge of this subject has been slightly extended, although it still remains very incomplete.

Ashmead, having noticed that scarlatina is very rare in Japan, which leads one to attribute a certain immunity to the native race, inoculated a Japanese with the scales of a young German in the twenty-fifth day of his illness; he flattered himself that he had thus obtained a serum conferring immunity on the European race. The day after the inoculation and the day after that the subject experimented on had slight headache, and the forearm inoculated was slightly swollen. On the third day a scarlet ring was observed around the wound caused by the inoculation; the throat was red, and there was fever and itching. The following days the ring remained stationary, then retroceded, and finally commenced to desquamate on the eighth day. At the end of twenty days the patient was well. The convalescence had been slightly retarded by a recurrence of the sore throat. In this case the scarlatina, if it was scarlatina, ran a rather abnormal course.

Stickler took mucus from the throat of a scarlatinal child, and dissolved it in a 1/600 solution of carbolic acid. Injected into guinea-pigs, this only caused very slight local reaction; two or three children out of the ten (of white race) whom he inoculated nevertheless developed either abscesses or sloughs. The shortest duration of the incubation was thirty-two hours, the longest seventy-two hours. Redness of the throat, in other words the eruption, was constant, except perhaps in one case. The ordinary painful throat appears to have been absent in two cases, and to have been very ephemeral in the remainder. No mention is made of diphtheroid exudations; in two children nephritis was noted. By good luck there were no deaths.

These experiments show that scarlatina may be conveyed by cutaneous inoculation when the incubation period is short, the sore throat slight or *nil*, but redness of the throat is pretty constant. With respect to the starting-point of the eruption nothing is said; in Case IX. it is, however, permissible to think that the exanthem was more pronounced in the neighbourhood of the little wound, because there was an "extensive desquamation all round the point of inoculation." If we compare these results with the clinical aspects of surgical scarlatina, we find they have this in common: a shorter incubation period than that of ordinary scarlatina, and milder throat symptoms.

At the International Medical Congress at London, Howard Marsh recalled that Mr. (now Sir) Thomas Smith had observed seven cases of scarlatina in forty-three lithotomised children. At that time, surgical and medical patients occupied the same building, and when the services were isolated, surgical scarlatina became very rare.

The twenty-five observations of surgical scarlatina collected in the practice of Paley, at Guy's Hospital, and published by Goodhart, are all of them very briefly recorded, rendering impossible a retrospective diagnosis; the fever may therefore not improbably include sundry cases of septicæmic, toxic or other form of erythema; but the fact remains that these eruptions often occurred in series, that contagion was often possible, and that these cases fell off directly a redistribution of the patients enabled infectious subjects to be isolated, instead of, as previously, occupying the same building as the traumatised children.

The work of E. Koch is still more convincing. Between 1875 to 1882, at the Hospital for Children at Bâle, not a single case of scarlatina occurred among the diphtheritic patients. From 1882, for some reason, scarlatina appeared in those operated for diphtheria in short series of four or five cases. The first patient in each series was usually a child who had not been tracheotomised, and had probably contracted scarlatina outside; twenty-one cases of scarlatina occurred, fifteen of which were in tracheotomised subjects. Among the other patients during this same period sixteen cases of scarlatina occurred, also grouped in short series.

In 1886 the scarlatinal subjects, who had, till then, occupied the same building, were transferred to another building, and thenceforward no cases of scarlatina occurred in the surgical patients except one case in 1887, and in the tracheotomised subjects it disappeared for nearly two years, after which two little epidemics occurred.

The fact that surgical scarlatina may occur in epidemic series, with all the appearances of infection, fully justifies me in asserting a connection with medical scarlatina.

Clinical proofs of the relationship between surgical and medical scarlatina exist in the description which we gave of the first of these affections. Taken as a whole, this description reproduces almost exactly that of ordinary scarlatina. The differences which are noted are five in number, and bear on the proportion of children attacked, the duration of the period of incubation, the throat symptoms, the starting-point of the eruption, and the date of onset of desquamation. We need not take cognisance of the changes in the wound, because this symptom belongs exclusively to surgical scarlatina.

The proportion of children under ten is, in medical scarlatina, 90 per cent.; in surgical scarlatina it is reduced to 75 per cent. This difference may be explained by the fact that, in the young, traumatisms are numerous, and, so to speak, of daily occurrence, but of little gravity; they are consequently easily overlooked, and their possible relationship to scarlatina is therefore missed. In the adult, on the contrary, traumatism is rarer, but more violent, and the patients, as is well known, do not fail to take note of it.

The second clinical difference between the two varieties of scarlatina is the difference in the duration of the period of incubation. This is on an average two and a-half days in traumatic scarlatina, and three or four days in the medical variety, a difference of about a day. We may suppose that cases (incorrectly) diagnosed as scarlatina contributed to the former minimum; but we must not forget that in the experiments of Stickler the incubation period averaged thirty-two hours, and clinical observation confirms this experimental result. It is, therefore, permissible to regard the shortness of the period of incubation as one of the characteristics of surgical scarlatina.

The third difference concerns the throat symptoms, which, in traumatic scarlatina, are slight, and were even absent in ten cases, while in ordinary scarlatina they are pretty constant, often pultaceous and diphtheroid, or even diphtheritic. To explain this difference we must repeat that, in the mass of observations of surgical scarlatina, infectious or other erythemata must have slipped in, which do not generally comport throat lesions, or at most only faucial redness. But once again we must refer to the experiments of Stickler, in which the throat symptoms were very slight, and was absent in one case out of ten. We must therefore hesitate to admit the cases in which throat symptoms were absent, although this default does not justify our rejecting them. The mildness of the throat symptoms or simple redness of the fauces does seem, as a matter of fact, to be peculiar to traumatic scarlatina, or at any rate to certain cases thereof.

A fourth difference is furnished by the starting-point of the eruption. In surgical scarlatina the eruption often starts from a peripheral lesion, spreads like lymphangitis, and finally invades the whole of the body. This appears to be a very abnormal course, assuming the infection to be communicated in the same way as medical scarlatina; but it appears quite natural, if we suppose that the traumatism was directly a factor in enabling the germs of scarlatina to penetrate *via* the solution of continuity thus established; in other words, by producing inoculation scarlatina.

A last difference exists in the slightly earlier advent of desquamation which appears, at the earliest, about the sixth or seventh day, in cases of surgical scarlatina, while in medical scarlatina, it only appears from the sixth to the ninth day. It is difficult to suggest a reason why desquamation should be earlier in one case than in the other; moreover, this would not appear to be an essential characteristic of traumatic scarlatina, and may be the result of error of diagnosis. As we shall presently see, scarlatiniform or scarlatinoid erythem is characterised by earlier desquamation than ordinary scarlatina.

We will now discuss the relationship of scarlatina to traumatism; in other words, the mechanism of infection in surgical scarlatina. Several hypotheses have been emitted on this subject:—

1 The infection may have taken place either a little before or just after the trauma, and the coincidence of the two may be pure coincidence.

2. Scarlatina may supervene in a wounded subject as an intercurrent affection.

3. The trauma may have weakened the resistance of the organism, thus favouring the development of scarlatina, which, under other circumstances, might have remained latent.

4. The trauma may have afforded an entrance and inoculated the infection of scarlatina *pari passu*.

Of these four hypotheses, the first two would withhold from the traumatism any direct influence in the development of scarlatina. The other two, on the contrary, recognise a relationship between scarlatina and traumatism.

The first that of simple coincidence, admitted by König and especially defended by Treub, seems to bear only on exceptions. As a matter of fact, if traumatism goes for nothing, we must suppose that the contamination occurred either before or after the injury, and in which event the attacks of scarlatina should be more or less uniformly distributed over the days following the traumatism. But this is not the case, for our statistics give, in the first three days, a minimum of nineteen cases a day, while the following five days only give four. This distribution is observed not only in isolated cases, but in the total statistics of Goodhart, Koch, Sörensen and Murray.

The second supposition, that of intercurrency, is suggested forthwith by the hospital series of Goodhart and Koch. Some of their patients only contracted scarlatina a long time after their admission to hospital (several weeks, a month or more). In these cases we may admit that the infection took place in the usual way, and that the scarlatina was merely an intercurrent affection; *i.e.*, it was scarlatina in surgical patients, and not surgical scarlatina, properly so called.

We must, however, bear in mind that, in the long pre-scarlatinal periods the patients were tapped several times, that on each occasion they had little wounds, and that the scarlatinal germs, if present in the environment, were able to enter the circulation through the wound, thus provoking a genuine traumatic scarlatina. Goodhart and Nossovitch, it is true, regard this mode of entry as very doubtful; they think it strange that the scarlatinal germ should resist the germicidal action of the antiseptic dressings. The remark seems just enough when it refers to a fresh antiseptic wound, but a suppurating wound of long standing is practically impossible to render aseptic solely by means of dressings, while, in respect of the granulation layer, we all know how fragile that is.

Of the two hypotheses just discussed the first deals with exceptions and the second with cases of scarlatina which appear so long after the traumatism that they cannot be attributed to it. There remain the cases in which the interval does not exceed, or exceeds but little, the ordinary duration of scarlatinal incubation. These may be explained, according to circumstances, by one or other of the two hypotheses which still await investigation.

The influence of traumatism on susceptibility, since the famous experiment of Max Schuler and the publications of Verneuil, is too well established to be disputed here. A certain number of cases, moreover, plead in favour of this opinion. Lippmann observed a recurrence of scarlatina in a child who had been struck; the germs of the first attack, in a latent condition, found, no doubt, thanks to this trauma, fresh conditions favourable to the reinfection of the little patient. Koch states that among 127 tracheotomised children at the Hospital for Children, at Bâle, there were fifteen cases of scarlatina; while of 151 non-tracheotomised children there were only six. Murray, in a ward which contained twenty-three operated and four non-operated patients, noted six cases of scarlatina in the former and one in the latter. At first sight the proportion seems the same, but we must bear in mind that five out of twenty-three operated subjects had already had scarlatina, whilst the four non-operated subjects had not had it. Sörensen records the instance of three sisters who were all three attacked by diphtheria and removed to hospital at the same time. The two eldest were tracheotomised and contracted scarlatina; the youngest, who was not operated on, remained free from it. Thus traumatism does not confer immunity as Treub affirmed was the case; on the contrary, it predisposes to scarlatinal infection.

The precise mechanism of its action may be explained in several ways. The infection may be more or less coincident with the traumatism or only develop in the days following, owing to the vital depression caused thereby; it may take place *via* the throat, as in medical scarlatina, or be conveyed by the blood and localise itself at the site of the injury (Volkovitch). The latter process might explain exanthemata starting at the periphery, and the slight severity of the morbid phenomena in the throat.

There are cases, however—and they are numerous—in which the incubation period is extremely short (half a day, one, two, or three days at most), and the traumatism quite trivial. It would, therefore, be absurd to have an argument on any supposed increase of susceptibility determined by the traumatic lesion. But if we bear in mind the shortness of the incubation period in the experimental scarlatina cases of Stickler, nothing is more natural than to admit the existence of traumatic inoculation, especially as, very often, the surgeon, the patient, or the person who inflicted the wound, may have treated scarlatinal patients, or may have been actually suffering from scarlatina. Traumatism and contagion thus act simultaneously in respect of the wound; the spread of the eruption from the wound, and the diphtheroid changes which it may undergo, thus find a perfectly natural explanation.

It is precisely in the cases where the existence of inoculation scarlatina was possible, that we have reason to complain of the silence of authors in respect to the changes in the wound itself. If it had been observed that the wound, like the tonsils, was covered with a diphtheroid exudation at the onset or during the course of scarlatina, we should have gained a fresh proof both of the path followed by the germs and the correctness of the diagnosis. The reason why I insist so much on a symptom which was only once mentioned (Beaudouin) is because L. Meyer and Sörensen have both met with it in puerperal scarlatina, the homologue of surgical scarlatina. "It is quite possible," says Sörensen, "that the infection gains an entry by the genital passages, because in parturient women the scarlatina presents a very special feature, viz., the absence of sore throat and the diphtheroid and inflammatory aspect of the external genitals. In patients tracheotomised for diphtheria who subsequently developed an eruption similar symptoms are noticed; sore throat being absent, but a copious exudation covers the lips of the tracheal wound. We must admit that the symptom in this case loses much of its importance.

To recapitulate, a certain number of cases have been included under the head of surgical scarlatina, in which the scarlatinal infection was not of surgical origin, but was merely scarlatina occurring in a surgical subject, as an intercurrent disease; in such cases it is "scarlatina of the wounded" and not "surgical scarlatina." The term traumatic or surgical scarlatina ought to be restricted to cases in which the traumatism appears to have determined a diminution of resistance of the organism with regard to infection, and still more to those in which the wound at the same time opened the door and effected the inoculation. In both the eruption follows closely on the trauma.

If there are all sorts of reasons for admitting the existence of surgical scarlatina, and even for regarding it as frequent, its diagnosis, to be maintained, requires the rigid exclusion of everything that may resemble it

Scarlatiniform eruptions are met with under many circumstances, but chiefly (1) following certain drugs; (2) as a manifestation of various dermatoses; and (3) in septicæmia.

The diagnosis of toxic exanthemata is generally facilitated by the history. The patient has been taking belladonna, copaiba or mercury; he has been inoculated with a serum (venous transfusion, injections of antidiphtheritic serum); he has been dressed with blue ointment, iodoform, carbolic acid, &c. If there are no indications in the history, these eruptions always present certain polymorphic peculiarities.

Carbolic acid eruptions are generally seen in the regions subjected to its action; there is continuous œdema without albuminuria, but when the irritating action is prolonged little vesicles or pustules form; the urine may become black or contain albumin. The appearances only resemble scarlatina in many exceptional circumstances; and any confusion between this kind of eruption and scarlatina must be a very rare occurrence.

Balsamic eruptions (copaiba, cubebs, &c.) are usually of the roseolar type: small lenticular patches of a rose-red colour are scattered over the skin which is healthy between them, while in scarlatina the eruption appears in large patches which soon coalesce. Fever is usually absent with medicinal eruptions.

The belladonna eruption is of a much more scarlatinal type, but its evolution is rapid and is not followed by desquamation. The fever is usually trivial, and other symptoms of intoxication may be discovered (mydriasis, dryness and constriction of the throat, parched feeling of the mouth, &c.). Here again it is difficult to believe that they have ever been confused, either the one or the other, with traumatic scarlatina.

Mercurial exanthema deserves closer attention, since very slight doses of the poison are sufficient to bring about its appearance. Mercurial intoxication does not, however, in its ordinary forms, bear much resemblance to scarlatina; the eruption, pretty general, occupies the lower part of the belly and the upper part of the thighs; at its periphery it has a roseolar aspect; the patient complains of salivation, a metallic taste, and the examination of the gums reveals the characteristic lesions. In its grave forms, it is true, the mercurial eruption may be of a scarlatinal type; the urine may become albuminous, and the temperature may be raised. It is questionable, however, whether in presence of such a well-marked intoxication the buccal symptoms can be absent or be overlooked by the observer.

Under the name of acute scarlatiniform erythema, or "scarlatinoid," certain eruptions of diverse or obscure origin are described which may give rise to considerable difficulty in diagnosis. The eruption has, indeed, a scarlatinal appearance, the throat is red, albuminuria may be found, and desquamation occurs in large scales; and if the patient happens to have received some injury the case may be described as surgical scarlatina. A careful examination enables us, however, to recognise certain differences between the two affections: The eruption of scarlatinoid subjects has not usually that scarlet tint which seems to be characteristic of both surgical and medical scarlatina and which the English call "the lobster-like look." Nor has the tongue that bright-red appearance, "strawberry tongue," and that varnished aspect which, with the white deposit in the centre, constitutes what is known as the "strawberry tongue." In scarlatinoid subjects the throat may be red, but in no case do we observe genuine sore throat with painful swelling of the tonsils. Though the desquamation may occur in large scales, it is generally early. According to M. E. Besnier, it appears when the eruption commences to fade, *i.e.*, two or three days after its appearance, while in surgical and even medical scarlatina it rarely appears until towards the sixth day. The eruption of scarlatinoid subjects is often itchy, which is rare in real scarlatina.

It is incontestable that the clinical picture of scarlatinoid subjects is singularly like that of surgical scarlatina, especially as, in the latter, the throat symptoms are slight or merely eruptive. It is, therefore, quite likely that several cases of this kind have slipped in among the observations of traumatic scarlatina, especially the cases where the throat presented no abnormal appearance, or in which desquamation was very early. I question, however, whether the error has been as frequent as is supposed, because contagion or epidemicity accounts for a good third of the cases, and because the desquamation appeared, at the earliest, on the sixth day, that is to say, at a relatively advanced period.

The recurrent scarlatiniform erythema described by Féréol has, not improbably, often been mistaken for scarlatina, and it is perhaps on this account that opinions are divided as to the frequency or rarity of the recurrence of scarlatina. However this may be, and as will appear from the observations of Féréol, Rossigneux, and Kramstyck, these kinds of eruptions are met with mostly in nervous subjects, especially in females; they occur from very slight causes, emotional or traumatic; they are generally itchy, have a copious desquamation, are not accompanied by throat symptoms, and recur with the greatest facility, one patient of Kramstyck having had nine attacks.

I have referred above to three patients, those of H. Page, Konetschke, and Schäffer, who had had, the first two, three attacks, and the last, two attacks. In reference to Page's case we must bear in mind that the third case, in spite of the objections which may still be raised, had very much the appearance of true scarlatina, since one of the students was attacked in his turn by it. But the cases of Konetschke and Schäffer seem *à priori* much more questionable; in the first subject the throat did not show any change; it could not be examined in the second, who had tetanus; in both cases the eruption was associated with miliaria, which is rare in scarlatina, and in one of the subjects the skin became somewhat œdematous, without albuminuria, another equally exceptional peculiarity; lastly, the recurrence took place less than fifteen days afterwards, sometimes even before the first eruption had altogether disappeared. It must be admitted that we are confronted with many anomalies.

We must always think of septicæmic eruptions in the presence of a scarlatiform eruption in a surgical subject suffering from suppurating lesions. Although, theoretically, confusion is possible, I think that in practice distinction is comparatively easy. First of all, these eruptions do not appear to be very common; Verneuil was one of the first to describe them, and since then the only cases on record are those published by Tremblay, Terrillon, Savart, Gilbert Ballet, S. Manning, Bosc, Auché and Læsel, J. Weiss, Colleville and de Bovis.

These eruptions are not usually of a frankly scarlatinal type; the patches or stains, which are rarely scarlet, are irregularly distributed. In one of Verneuil's cases they occupied the dorsal aspect of the limbs, they occasionally invade the face, but there is no sore throat. The desquamation which follows is branny or in small scales, and is most marked in the neighbourhood of the wound. There may also be itching (Colleville and de Bovis), which is a rare symptom in scarlatina. Moreover, these patients are generally feverish, even before the eruption, for they are already the victims of an infection either medical (Manning) or surgical; and in the latter case we usually observe a closed, or more or less patulous focus of suppuration. Among other associations are: Anthrax, (Verneuil), metritis and abortive pelvi-peritonitis (J. Weiss), gonorrhœa (G. Ballet), prostatic abscess (Bosc), retro-mastoid sub-periosteal abscess (Colleville and de Bovis), &c. The eruption may be covered with miliaria, or even petechia (Auché and Læsel). Lastly, the temperature, with its irregular oscillations, does not at all resemble the febrile curve of scarlatina. Such mistakes have probably not been frequent; nearly half the cases we have mentioned go as far back as the commencement of the antiseptic or even to the pre-antiseptic period; thus it is certain that surgeons of that epoch knew pyæmia and septicæmia too well not to be able to diagnose them.

With regard to septic exanthemata, we know that vaccination may be followed by the appearance of various eruptions, sometimes of a scarlatiniform aspect, but these can always be distinguished by the peculiarities just mentioned. We have seen that E. Koch claims to have observed true scarlatina following vaccinal inoculation.

To sum up, the relationship between scarlatina and traumatism seems to be real. If, at the present time, surgical scarlatina is less frequent, it may be explained by the more perfect isolation of infectious subjects, and by the progress of medical antisepsis.

From a pathogenic point of view the relationship may be simply due to chance or to the intercurrent development of the infectious complaint; but the cases are few in support of this explanation, and do not establish anything more than the occurrence of "scarlatinas in the wounded." True surgical scarlatina appears soon after the traumatism, either by the latter creating a *locus minoris resistentiæ*, or by direct inoculation of the germ of scarlatina.

There is no reason to suppose that "scarlatina of the wounded" differs from ordinary scarlatina. On the contrary, in those cases in which traumatism could be invoked, either as having favoured the development of scarlatinal germs in the wound or by inoculating them therein, the clinical picture is slightly modified. The incubation period is reduced as compared with ordinary scarlatina, the eruption appears first around the wound, which may assume a diphtheroid or gangrenous aspect, and the throat symptoms are very slight and may even be simply eruptive.

The predisposition which traumatism engenders in the direction of an exaggeration of susceptibility to scarlatina seems, in any case, quite real: moreover, the surgeon who has been in contact with scarlatinal subjects or who moves in scarlatinal surroundings, ought to abstain from operating, at any rate until he has taken the most rigorous measures of disinfection and antiseptic or aseptic precautions, not only in respect of his person, but also his assistants, his patient, and the premises.

Professor Orth, of Göttingen, has been appointed successor to the late Professor Virchow, to whom thirty years since he acted as assistant. He has been Professor at Göttingen since 1878.

DILATATION OF THE STOMACH. (*a*)

By NOEL D. BARDSWELL, M.D., M.R.C.P.,
Physician to the Sanatorium, Mundesley,
AND
J. E. CHAPMAN, M.R.C.S., L.R.C.P.,
Clinical Pathologist to the Sanatorium, Mundesley.

The following conclusions have been arrived at as a result of routine examination of stomachs in all cases under our care for the treatment of pulmonary tuberculosis.

1. Practically in all cases of early disease, whether slight or fairly acute, of say from three to six months duration, the stomach is found to be normal in size, the only exception being those who give a history of prolonged antecedent dyspepsia. This means that as far as the tone of the stomach is concerned, generous ordinary diets can safely be given, practically to all early cases, with the exception of chronic dyspeptics. The importance of examining stomachs in such cases, before administering ordinary sanatorium diets, is obvious.

2. That although the stomach of early cases will usually stand the administration of very large diets, there is a tendency for prolonged hyperfeeding to cause dilatation, and this dilatation may exist without giving rise to any symptoms of dyspepsia. In the event of a relapse, however, this condition, as a probable precursor of atonic dyspepsia, would certainly be a cause of anxiety.

Clinical experience suggests that other things being equal the longer such patients are kept at absolute rest (and such treatment usually implies the existence of fever) the greater the tendency to atony and dilatation.

3. That sanatoria cases admitted with acute extensive disease who will probably be some three to six months before losing their fever, and who consequently will be largely at rest for that period, run greater risks of developing atonic dyspepsia and later dilatation of the stomach than any other type of consumptive. The prolonged administration of huge ordinary diets to consumptives of this clinical type, especially after the development of symptoms characteristic of atonic dyspepsia, is, in our opinion, absolutely unnecessary and unjustifiable in view of the serious prognosis which must be given when active pulmonary tuberculosis is associated with dilatation of the stomach.

During the past two years we have had under our care eight patients (originally of the acute type of pulmonary tuberculosis which we are now considering) who had previously been some six months in sanatoria where excessive feeding is practised. In five of these patients we found definite enlargement of the stomach, and in each case this was associated with marked anorexia, dyspepsia, vomiting of yellow fluid before breakfast, and general malaise throughout the day, symptoms which had existed for a long period.

It is only fair, however, to record that in four out of the five cases the disease in the lungs had obviously been considerably arrested by the treatment. It is interesting to note that in three of these same patients the anorexia, dyspepsia and vomiting entirely cleared up under more physiological dieting, and that in two the stomachs largely recovered their tone, one, in the course of three months, retracting from 21 cm. vertical measurement by 15 cm. transverse measurement to 18 cm. and 12 cm. in the same diameters, and the other in the course of fifteen months gradually retracting from a measurement of 15 by 14·5 cm. to one of 9·5 by 11, this latter being the average of the normal stomach (Addison).

Another case entirely under our own care is of interest from this same point of view, viz., that of a young man admitted with acute and extensive disease, with high fever, &c. After four months' treatment at rest on a weighed diet, he had lost his fever, gained 26 lbs. in weight, being now a trifle over his normal weight, and was convalescent; but although he had normal appetite and digestion his stomach measurement had increased from 15 cm. by 15 cm. (on admission) to 18 by 16. The average value of his diet for these four months was: Proteid 137, fat 135, and carbohydrate 269.

The following is a sample of the actual diet taken in a day:—Milk, 3 pts.; soup, 7 ozs.; eggs, 2; chicken, 3 ozs.; mutton, 3 ozs.; potatoes, 4 ozs.; butter, 2 ozs.; bread, 5¼ ozs.; sugar, ¾ oz.; milk pudding, 5 ozs.; and stewed apple, 4 ozs. These somewhat odd amounts taken are accounted for by the fact that the diet was calculated in grammes.

By the end of the next four months he was completely restored to health, with arrested disease, and was walking seven miles daily.

On examination at the end of that period his stomach was found to be normal again, though his diet had remained unaltered.

In this patient the stomach was probably saved by his making a good recovery and thus being able to take considerable exercise; if, on the other hand, he had drifted into chronicity and persevered with the same diet, he would almost certainly have become a victim to atonic dyspepsia with a dilated stomach.

On the strength of experiences of this sort, we now, when dealing with similar cases with symptoms of atonic dyspepsia, amend the diet by reducing its bulk without diminishing its nutritive value. The following is a sample of such a diet:—Milk, 2½ pts.; eggs, 2; fish and meat, 5½ ozs.; butter, 2 ozs; milk pudding, 7 ozs.; arrowroot or cornflour, 4 ozs., plasmon, 1½ ozs.

The weight of this diet is 74 ozs., as against 98 ozs. of the former, or a reduction of 25 per cent., and its nutritive value is a trifle higher, viz., 147 of proteid compared with 137, the fats and carbohydrates being the same in both.

4. Chronic cases of several years' standing have almost invariably pronounced anorexia and dyspepsia, and in our experience about 50 per cent have some degree of stomach dilatation. In spite, however, of their frequently starting treatment thus handicapped, their stomachs appear to stand sanatorium treatment better than one would expect.

The facts that the majority of chronics are sufficiently convalescent to take exercise, and that they are very difficult indeed to stuff on account of the anorexia may help to account for this.

THE
USE OF CHLORATE OF POTASH
IN THE
TREATMENT OF CASES OF HABITUAL DEATH OF THE FŒTUS IN THE LATER MONTHS OF PREGNANCY. (*a*)

By ROBERT JARDINE, M.D., F.R.S.E.,
Senior Physician to the Glasgow Maternity Hospital, &c.

The author remarked that this method of treatment had been introduced more than a half a century ago by Sir Jas. Y. Simpson, who had introduced it

---

(*a*) Abstract of paper read at the British Medical Association Annual Meeting, July-August, 1902.

(*a*) Abstract of paper read before the British Medical Association Meeting, Manchester, July-August, 1902.

with the idea that oxygen would be given up to the maternal blood and the fœtal blood would thus be aërated in spite of the degeneration of the placenta. The chlorate did not give up its oxygen, but it had a beneficial action through the endometrium.

Dr. Jardine remarked that some years ago he had incidentally mentioned this method of treatment in a clinical lecture on abortion, and had been severely taken to task by a writer in a therapeutical journal, who had maintained that the continued use of chlorate of potash would assuredly act deleteriously upon the maternal blood. He (Dr. Jardine) had found by experience that in these cases this theory was quite erroneous. He gave the drug in ten-grain doses thrice daily from about the end of the third month onwards until delivery.

Case I.—A multipara with two previous stillbirths came under observation when six months pregnant. There was no evidence of syphilis. She was given the chlorate, and was delivered at full time of a healthy child and a macerated premature one. The latter had been dead when the patient began to take the chlorate.

Case II.—A multipara, who had had three stillbirths, was treated from the fifth month and went to full time. The child was strong and healthy.

Case III.—This patient went to full time on three occasions when taking the chlorate, and on at least five other occasions miscarried. On one occasion immediately after delivery she seemed to be dying. There had been a fair amount of post-partum hæmorrhage, and a douche had been given when the patient began to gasp and said she felt as if her chest had an iron band round it. She asked to be changed from her left to her right side, and Dr. Jardine turned her over, when she immediately drew a long breath and said she was all right. He thought that it must have been a case of air embolism.

In conclusion, he mentioned the alternative treatment by induction of labour, which he had tried in one case of his own, and had been associated with Dr. Reid in another case. In both cases the child had been born alive but had died within a few days. He therefore preferred administering the chlorate and allowing the patient to go to full time.

Special Articles.

CRIMINAL STATISTICS, IRELAND.

The Twenty-fourth Report of the General Prisons' Board, Ireland, for 1901-1902, just published, is an interesting record of the criminal classes in that country. As we turn the pages of the report we are struck with the fact that our prisons have ceased to be torture chambers and have become disciplinary and reformatory. The spirit that actuated Elizabeth Fry still lives, though the philanthropic effort of to-day lacks the personal influence of the early movement. The keynote of the present system is employment; old and young criminals, short-termed prisoners and long-termed ones are provided with a daily task; occupation is found for all. In the case of those undergoing a long term of imprisonment a trade is taught, and before the term is completed the prisoner, by his industry, becomes more than self-supporting, and his mind has become familiar with healthy thought his trade has necessitated. The current of his thoughts has come to run in a new channel, and he has learned that industry can secure money and creature comforts without the risks of crime. So far, the experiment has borne good fruit, the percentage of failures being comparatively small. Very interesting is the deterrent influence of the inebriate homes to which old offenders are sent. It is too soon to expect them to produce a marked effect on drunkenness, which is so dependent on the prosperity of the people; but an enforced residence for months in an inebriate home, where work is enforced and stimulants are not allowed, is deterrent, and the care of the physical condition during detention so builds up the strength that the offenders are better able to resist the temptation of drink on regaining liberty. To the physician, the morbidity statistics are of interest, and it tells greatly to the credit of the medical officers of these institutions that the cases are so few, particularly, as many of the more serious diseases were contracted outside the prisons. In all Ireland there were but two cases of typhus fever, both of which were contracted before admission; of typhoid there were but eight cases, none of which could be traced to any water or food pollution, and as there were cases of the disease in the immediate neighbourhood it is reasonable to conclude that the toxin was air-borne. Of alcoholism, including delirium tremens, there were 775 cases; of rheumatism, 906 cases; syphilis, 279 cases; scabies, 351 cases; neuralgia, 714 cases; chronic bronchitis, 358 cases; bronchial catarrh, 478 cases; and of catarrh, 627 cases. Withal there were but six deaths from disease—two from pneumonia, two from cardiac syncope, one from tuberculosis, and one from uræmic convulsions. When we think of the class from which these patients come, the statistics of these 19,494 patients is an honourable testimony to the skill and attention of the medical officers.

The appendix gives particulars of each case of insanity among prisoners in local and convict prisons during the year ending December, 1901, and of the seventy-eight cases we find that no less than thirty-nine were persons connected with agriculture, fifty-two of the whole number could both read and write, and that fifteen could neither read nor write. This is a large percentage of illiterates, for fully 85 per cent. of the population between ten years and thirty-five can both read and write, and is something to the credit of the beneficial effects of education. Those who give alms indiscriminately to importunate beggars might with advantage note that of two beggars committed to prison as vagrants one had £2 10s. 3d. in his possession, together with a bank book showing £114 0s. 9d. to his credit, while another had £60 15s. 5d. Lastly, we would note the decrease in the number of convicts in custody on January 1st for some years past: In 1855 they numbered 3,427; in 1860 they were 1,631; in 1870, 1,230; in 1880, 1,031; in 1890, 578; in 1900, 329; and in 1901 they had fallen to 292. A decrease which may be looked on as an unequivocal proof of the improved condition of the people.

SCOTCH LUNACY BLUE-BOOK.

The Forty-fourth Annual Report of the General Board of Commissioners in Lunacy for Scotland is charged with interest, to the lay reader as well as the medical, and it well maintains the reputation of its predecessors. The total number of persons of unsound mind at January 1st last, who were under the supervision of the Commissioners' Office, was 16,288, an increase of 389 over that of the previous year. During the year the following changes have taken place as regards the registered insane. Private patients in asylums have increased by 44, and in private dwellings by six; pauper patients in establishments increased by 358, and decreased by 38 in private dwellings. The increase of pauper patients in establishments during the past year has been 84 in excess of the average of the past ten years. The average recovery rate in Royal and district asylums was 39 per cent. of the admissions, and in private asylums 43 per cent. There were 227 private patients discharged recovered during 1901, which is six below the average for the five years 1895-99. The number of pauper patients discharged recovered was 1,268, which is 59 above the average for the five years 1895-99. The number of patients discharged unrecovered, excluding transfers, was 517 (114 private and 403 pauper). The death-rate for private and pauper patients was 8·0 and 8·5 per cent. respectively on the average number resident. Table X., Appendix A, shows the annual number of deaths, and classification of the causes of death, of patients who died in asylums and other establishments, for each year from 1870. General paralysis, as a cause of death, continues to increase, especially among males. Death was attributed to this disease in the case of 136 males and 31 females. During the year 152 patients were liberated on probation from the various institutions. The Commissioners think a more frequent use of this form of discharge in some of them would probably lead to a larger number of permanent discharges taking place.

The important question of changes occurring among the attendants and servants is again introduced. The whole number who left, were dismissed or died, was 977, which is 67 less than the number recorded for the previous year. The number who resigned their situations voluntarily was 706, 50 left on account of ill-health, five died, 29 absconded, 52 were dismissed for incompetence or unsuitability, six on account of their services being no longer required, and 129 for misconduct. The Commissioners again recommend that the administrators of asylums in which changes among attendants occur frequently should inquire carefully into the causes, and should endeavour to remove them by offering increased inducements to good attendants to remain, and to a better class to take service. Their experience tends to show that, in the case of men, a high class of attendant and security for permanent service are best obtained by increasing the number of married attendants. We have on numerous occasions advocated the adoption of these recommendations, but we must admit there are often untrustworthy reasons assigned for leaving, and many causes which are difficult to fathom and comprehend. The problems of asylum service are undoubtedly difficult, and all asylums do not occupy the same favourable position. Some easily find material of service, while others experience great difficulty, and geographical position, nearness to towns, certainly play an important part in the stability of a staff. There is no doubt the service is trying and the hours long, and that the absence of pensions in Scottish asylums is a great drawback. The Commissioners seem to have great faith in the register they keep of attendants and servants dismissed for misconduct, and that it prevents these persons from securing a permanent engagement in another asylum. We know this register does good, but if it were conducted on a more elaborate scale it would prove of real assistance to superintendents.

The whole number of escapes during 1901 was 190. Of these, 96 were brought back within 24 hours, 45 within a week, and 19 after a week. There were 30 still absent on the expiration of 28 days. The whole number of accidents reported was 264. Of these, 17 ended fatally, death in eight of these cases being due to suicide. The circumstances of all the deaths by suicide and accident were investigated by the Crown authorities and the Commissioners. Embodied in the general report are reports by the Deputy Commissioners on the condition of patients in private dwellings. As usual, these reports contain much of interest regarding the management of the insane in private dwellings. Dr. John Macpherson reports it is worthy of record that in few instances was it suspected that the food, personal clothing, or the sleeping arrangements for the patients were defective. Dr. Sutherland is satisfied, having now traversed almost every parish in Scotland, and visited patients in 600 parishes, that the possibilities are great if only inspectors of poor as a whole, following the excellent example of a few, bestowed the time, labour, trouble and care necessary to make boarding-out a success. Dr. Charles Macpherson saw no patient who had the slightest appearance of being insufficiently fed, and the impression left by his visits was, on the whole, a favourable one. There is no doubt the system of boarding-out chronic insane men and women in private dwellings is a good one, and one we would like to see more popular with inspectors of poor and parish councils.

Some interesting information is given as regards the cost per patient in district asylums, of land and buildings, and of the maintenance of each patient. At May, 1901, pauper lunatics of Scotland maintained in district asylums were costing the country a yearly rent per head of £16 6s. 8d., which, added to the average cost for food, clothing, &c., gives the total cost of pauper lunatics in all district asylums as £43 4s. 9d. per patient. The question of cost is a matter of very great importance to the ratepayer, and nowadays there seems to be too great a tendency towards extravagance in the erection and furnishing of our asylums. When we think of asylums costing as much per bed as would build a comfortable cottage for a workman and his family, it seems nothing short of scandalous.

More could easily be said regarding this interesting and practical report, but space forbids our going further into detail. There is abundant evidence throughout the report of eager endeavour to safeguard the interests of the insane, and to convince the public that its insane poor are being well cared for, for which Scotland has every reason to feel grateful.

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, September 28th, 1902.

DILATATION OF THE STOMACH.

Prof. Robin, who is a recognised authority on gastric affections, has treated with a masterly hand the now well-known affection, dilatation of the stomach. However, he does not recognise the existence of the dilatation, in the absence of an obstacle, from atony, paralysis, or atrophy of the muscular tunic, which he qualifies as "rare." He admits only gastric distension, the consequence of spasm or stenosis of the pylorus allied to hyperasthenia with hyperacidity of fermentation. Under the name of dilatation Prof. Robin proposed to group functional troubles as atony or gastric myasthenia and lesions as dilatation by atrophy or degenerescence of the muscular coat.

Soupault, in a recent monograph, said that dilatation appeared as a secondary state, the pathological signification of which is subordinate to the very variable causes on which it depended, or, in other words, the diagnosis of dilatation is without meaning unless an explaining cause were added. For him dilatation was the *ensemble* of motor troubles, having for result a too prolonged sojourn of the aliments in the stomach, and as a consequence the delay of their passage into the intestines, whether the volume of the viscera were increased or not.

This definition corresponds fairly with the present idea of the question; dilatation (an improper term, since increase in volume is not indispensable) is the useless prolongation of aliments in the gastric ventricle, producing troubles more or less prolonged, more or less grave.

In a clinical point of view account may be taken of only two varieties, one of which is very important, dilatation due to an obstacle at the pylorus; it is the true dilatation according to Robin; the other, that described by Soupault, and due to insufficient contraction.

The causes which produce the first variety are numerous: they are intra or extra gastric. In the first group is found stricture of the pylorus, cancer, ulcer, polypi, fibroma; in the second, less important compression of the pylorus by the liver, kidneys, hypertrophied ganglions, spasms of the pylorus, &c.

The most characteristic signs and symptoms of the affection are, says M. Robin, epigastric undulation, tension of the same region, pain, regurgitation, eructations, vomiting, all of which follow the repast, persist an hour or two and disappear until food is taken again. When these phenomena appear a long while after taking food (two hours) the pylorus is very probably the origin of the trouble.

The treatment is medical and surgical. The former consists in the administration of alkaline solutions to diminish or destroy the hyperacidity of the gastric juice; in the employment of bismuth in large doses, and sulphate of soda as recommended by Prof. Hagem:

Sulphate of soda, ʒj;
Bicarbonate of soda ʒss;
Chloride of sodium, xx grs.;
Water, one quart.

Ten ounces of this solution are taken fasting in the morning, and in three parts, twenty minutes between each. The dose should be increased by two ounces, every morning, up to half a quart. Among other means recommended may be mentioned olive oil, antiseptic substances, washing out of the stomach, purgatives, massage, electricity.

The surgical treatment is gastro-enterostomy and pylorectomy. The former is reserved for all the varieties of ulcer of the pylorus, and is, concludes M. Robin, an excellent operation, while pylorectomy, which consists in the ablation of the tumour, is a much graver operation and not always favourable in its results.

Berlin, September 27th, 1902.

The *Deutsch Med. Zeit.*, No. 71, has a reference to a paper by Dr. Westphalen on

Round Ulcer of the Stomach.

As regards treatment, the author commences with the so-called abstinence treatment, in which nothing is given by the mouth beyond a little cold tea, or Vichy water, or bits of ice. If the abstinence is long continued, nutrient enemata are used. Rost, of the Augusta Hospital, keeps food by the mouth from his patients for six days. Whether food in the rectum sets up gastric secretion or not, it is an undoubted fact clinically that in cases of gastric ulcer the painful symptoms disappeared more quickly by withholding food from the stomach than by any other method of treatment. In an extreme case the author continued the abstinence for sixteen days. After completion of the abstinence period he gives four glasses of milk per day, increasing the quantity by half a glass each day. After ten to fourteen days he gives soups and more solid food. He counsels a long-continued milk diet (fresh milk or whey) with the addition of cream, which reduces the hyperacidity of the stomach, the milk food keeping the motility of the stomach at a minimum. Passing over local applications, such as poultices, &c., which many would think unnecessary, he gives large doses of bismuth, a heaped-up teaspoonful in a glass of water before breakfast in the morning. In no case does he keep his patient in bed less than three weeks. Even when all active symptoms have subsided, his patients must keep to a carefully regulated diet for at least a year. Von Sohler recommends a chiefly vegetable diet, as by this the hyperacidity is favourably influenced.

The *Therap. d. Gegenwart*, 3/1902, contains an article by Dr. v. Tovölgyi on the

Nerve Remedies for the Treatment of Laryngeal Tuberculosis.

In strong people with commencing tubercle of the larynx the disease must be actively treated. By insufflation of powder of any kind valuable time is wasted; it can at most only serve to clean the ulcers, and thus act as accessories to more active measures, galvano-caustic curettage, painting, &c. This latter is to be looked upon as the normal procedure, and among the remedies for local application lactic acid stands first. This, under local anæsthesia, should be applied at first as a 30 to 35 per cent. solution, but the strength of the solution should then be raised rapidly to 75 or 80 per cent. It is more suitable, however, since no local anæsthetic is required, to use a 30 to 50 per cent. solution of sodio-sulphoricinate of phenol, which is specially active in disease of the vocal cords. It has not the same favourable effect on ulcers as lactic acid. Orthoformol (25·150) is indicated when there is pain in the act of swallowing. Menthol in 20 per cent. oily solution is inferior to this; it may relieve the dysphagia, but it cannot always be borne, as it causes burning and stabbing pains. It is advisable not to use any remedy when no further improvement is observed from its use, and a change should then be made. If there come a time when all remedies seem to fail a pause should be made in the local treatment, and change of air recommended.

The *Prag. Med. Woch.*, 24/1902, contains an account, by Dr. Chiari, of so-called

Banti's Disease,

together with histories of certain cases. In 1894 Banti published some cases which he assumed to belong to a hitherto-undescribed form of disease, the essentials of which were primary enlargement of the spleen, with anæmia, with which were associated later cirrhosis of the liver and ascites. The cases described by Chiari were four in number, and were briefly as follows:—

Case I. was that of a young woman, æt, 18, who had malaria in her fifth year. In her fifteenth year she had a splenic tumour with anæmia, which improved for the time under quinine and iron. Diminution of the erythrocytes; leucocytes normal. Three and a-half days before her death the spleen, which weighed 1,250 grammes, was removed. At the autopsy a severe hepatitis, which had remained latent, was found. The liver was atrophied. Thickening of the carotids and of some of the cerebral arteries, coupled with the youth of the patient, placed the diagnosis of hereditary syphilis beyond doubt.

Case II. was that of a man, æt. 20, who died from pyæmia. The spleen was greatly enlarged. Alcoholism was denied. At the post mortem, along with the changes due to pyæmia were enlarged spleen, thickening of the spleen capsule, and thickening of the parenchyma chronic interstitial hepatitis, with cicatricial bands and ascites. Probably hereditary syphilis.

Case III. was that of a girl, æt. 20, who had had splenic tumour and anæmia from her third year. Clinically there were enlargement of the liver and ascites, diminution of the erythrocytes, leucopenia with lymphæmia. Death through bursting of a varix in the œsophagus. At the autopsy the usual condition was found, enlarged spleen with thickened capsule, hyperplasia of the parenchyma, old chronic hepatitis with firm cicatricial tissue. Probably hereditary syphilis here also.

Case IV. was that of a man, æt. 25, who had already been ill a year. Chronic cirrhosis with caput medusæ, enormous spleen, anæmia with extreme ascites. Malaria and alcoholism could both be excluded. Laparotomy showed that the omentum was extensively adherent, and the wound was therefore closed. The autopsy showed marked atrophy of the liver, enlarged spleen with connective tissue growth in the reticulum of the pulp. Here also the cirrhosis and enlarged spleen must be attributed to hereditary syphilis.

VIENNA, September 27th, 1902.

PNEUMO VASOMOTORS.

THE question of vasomotors in the lung has given rise to many hypotheses in physiology. Lichtheirn affirmed that the vasomotor action was well marked in the lung. Openchowski and Wagner stoutly asserted that it is *nil*. Strubell, in Basch's laboratory, has recently devoted his attention to the subject, and, in a paper read at the Medical Congress, gives a list of experiments which tend to prove some action of that nature in the lung. If, after injecting strophanthin both vagi be cut and the proximal ends stimulated, the blood pressure falls, but the frequency remains the same. The pressure in the left auricle will be correspondingly reduced, while that in the pulmonary artery will be somewhat increased and the lung-volume diminished, which proves the accuracy of Basch's early teaching of the pathological circulation of the blood, in which he demonstrated by models a reduction in calibre of the pulmonary vessels.

TROPHIC CUTANEOUS NEUROSIS.

At the same meeting Müller presented a female patient with a multiple gangrene of the skin which commenced after a scald on the right leg. Since that time, with five intervals, she has developed about thirty gangrenous patches within three years, which spread along the right leg with alarming rapidity. The onset is heralded by pain; reddening and vesication followed in seven or eight hours by the whole becoming gangrenous. Whether this was simply a case of multiple trophic neurosis, with consequent gangrene of the skin, or due to syringo-myelia, he was as yet unable to decide.

THE EFFICACY OF BATHS.

At the Congress Müller drew attention to the effect of baths on the circulation. When the water was not in motion the efficacy of the bath depended on the temperature or thermal stimulus. When the temperature is below the average normal the typical curves are altered in proportion to the variation in temperature, the blood pressure going up while the pulse declines in frequency. When the bath is taken at 40° C. (104° F.) there is a temporary rise of blood pressure, which, however, soon begins to sink, going below the normal, subsequently rising for a longer period. If the bath be taken at 38° C., the variation is not so great; but if above 40° C., the variation increases and continues longer, just as in the case of the cold bath, with the difference that the pulse is increased in frequency in the latter and reduced in the former.

In respect of baths in running water the intensity of the mechanical movement must be calculated, which is best illustrated by the "douche," which acts on the blood pressure independently of temperature, its effects being exerted violently and at once, but these effects are not so lasting as in the other forms.

CUMULATIVE ACTION OF DIGITALIS.

Fränkel has been experimenting with the different preparations of the drug in order to discover the least dangerous form. All the preparations appear to be bad, but "digitoxin" is the worst in this direction, and should therefore not be used when the drug requires to be continued for any length of time. Digitalinum verum, on the other hand, is quickly eliminated, and may be used with perfect safety for a long time.

Strophanthus is more fleeting in its effects, but equally efficacious in its action.

WORK AND BLOOD PRESSURE.

Schott has recently been experimenting with Gärtner's tonometer to test his former results, and he finds that half of the standard labour is sufficient to produce acute dilatation of the heart even in a healthy person. Exercise for treatment of heart disease should be moderate, and when the pulse and breathing become affected the effort should cease; up to this point the blood pressure is high according to the tonometer, but as soon as the breathing becomes affected and tachycardia with arhythmia appear the tonometer comes down even as far as 20 to 30 m.m. of mercury. This condition can be demonstrated in the healthy in sporting exercise, when it often becomes excessive.

Hoffmann thought the first sign of over-exercise was not the reduction of pressure, while the dilated action of the heart is often marked by its more powerful contraction. Arhythmia is not a sign of dilatation according to this observer. The distention of the heart is not a physiological condition, but a pathological state that does not appear and disappear rapidly, as some appear to suppose.

LIGHT THERAPY.

At the same meeting, Bie raised the question of treatment by light, but dwelt more particularly on "Light Biology." From his own experiments he found that the red, yellow, and green rays did not cause inflammation of the skin or lung tissues which was in accord with the results obtained by Bouchard, Widmark, and Finsen. The ultra-violet rays, on the other hand, caused a dilatation of the vessels in the living frames that lasted at least five or six months after. He is unable to allege any proof that light acts on the hæmoglobin, nor does he agree with Moleschott and others that light increases the elimination of carbonic acid.

The chemical rays of light, he admits, have a stimulating action on the lower animals, and probably act similarly on man; and in this regard the red rays are more active, while the violet rays, on the other hand, have a calming influence on the psychical centres: the latter, he considers, to be an active agent in the treatment of maniacal patients.

The red rays penetrate deeply into the organism, while the blue and violet rays are more superficial in their action, depleting the cutaneous blood vessels. The ultra-violet rays cannot be made to pass beyond the cutaneous tissues, a fact which at once proves their uselessness as germicides in the organism, therefore it is idle to talk about killing tubercle bacilli in the larynx or lungs by means of these rays, as has been affirmed by some American authors.

The Operating Theatres.

MIDDLESEX HOSPITAL.

Excision of Popliteal Aneurysm. — Mr. John Murray operated on a man, æt. 32, who was suffering from a popliteal aneurysm in the left thigh. The patient, who was a sign painter, had had syphilis twelve years ago, for which he had not been efficiently treated; he also had been rather a free drinker; he had never done any laborious work. He noticed pain in the left popliteal space a month before admission, and a week later he observed a swelling at the back of the knee; this gradually increased, and at the time of admission filled up the whole of the popliteal space. During the last week before admission he had suffered from severe pain in the back of the knee and leg, and had not been able to fully extend the knee. He complained that he felt out of sorts, and had completely lost his appetite. On admission the patient had rather a sallow complexion, and looked decidedly ill; his temperature was remittent in character, reaching 101° at night, and never falling below 99°; pulse 104 to 120. The heart's apex-beat was slightly displaced, and percussion showed the heart to be somewhat dilated; there was no cardiac bruit present, and the arteries did not appear to be rigid or tortuous. In the left popliteal region there was a tense swelling about the size of a large orange, filling up the whole space. The superficial veins over it were very prominent; there was pulsation of an expansile character; on compression of the femoral artery the swelling diminished and the pulsation ceased. There was a loud bruit in the aneurysm, and the pulsation in the dorsalis pedis was delayed. Any attempt to extend the leg caused great pain. The spleen did not appear to be enlarged. The urine contained no blood, sp. gr. 1010, with a trace of albumin. The patient was kept under observation for a few days at rest in bed, during which time the aneurysm steadily increased in size, so much so that the man had to keep his knee permanently flexed. It was therefore decided that an operation was necessary, and that excision of the aneurysm seemed the most suitable method of dealing with it. The patient was anæsthetised, and placed in a prone position, the left knee being supported by a pillow. A tourniquet was applied to the femoral artery at the apex of Scarpa's triangle; an incision 6 ins. long was then made over the middle of the popliteal space commencing above and slightly to the inner part just over the opening in the tendon in the adductor magnus and extending down to the lower limit of the popliteal space. The superficial tissues having been divided, the deep fascia was incised and the internal popliteal nerve which presented drawn inwards. An attempt was then made to separate the sac from the surrounding structures; the sac, however, ruptured on doing this, so it was freely laid open and the contents turned out. A careful search was next made for the popliteal vein, but this structure could not be defined; the point of entry of the popliteal artery into the sac was easily seen, and a ligature was placed round the vessel; in the same way the vessel below was easily secured. The sac of the aneurysm was shelled out, one or two vessels requiring to be secured by ligature. Before removal of the sac a cord was seen on its inner side, and this on investigation proved to be the popliteal vein completely blocked by a clot; the vessel was tied and part of it taken away with the sac; the tourniquet was removed, a few bleeding points ligatured, and after all oozing had ceased the wound was closed, a drainage tube being introduced, cyanide gauze dressing applied, and a back splint put on, the leg and foot being wrapped up in cotton wool. Mr. Murray said that the choice of operation here lay between excision or proximal ligature either of the femoral artery or of the popliteal just below the opening in the adductor magnus. He chose the former as being more likely to be effectual and, considering the size of the tumour, less apt to be followed by gangrene caused by interference with the anastomotic circulation; moreover, the rapid formation of the aneurysm and the rapid increase in the size of the swelling since admission into the hospital rendered this case in particular not well adaped to treatment by proximal ligature. If one of the two forms of ligature were in any case desirable, he said he would much prefer ligature of the popliteal in the upper part of the space, owing to the fact that it left the anastomotica magna intact. He mentioned a case on which he had operated two years before, in which the femoral artery had been previously tied for a popliteal aneurysm, but return of the aneurysm occurred; in this case he performed excision of the sac with a most satisfactory result. With regard to the origin of the aneurysm in the present case, the question arose, he pointed out, as to whether it might not be due to the softening of the vessel wall as the result of an embolism due to septic endocarditis; the patient's general appearance, his persistent temperature and quick pulse, suggested some constitutional disturbance, and the extremely rapid formation of the aneurysm was in keeping with this possibility. A careful examination of the heart, however, had failed to justify such a diagnosis, and bacteriological examination of the blood had given a negative result. With regard to the operation he had just performed, he pointed out that the important steps were the isolation of the internal popliteal nerve and of the popliteal vein; the nerve had been easy to find, but although a careful search was made the vein could not at first be discovered; this was subsequently found to be due to the vessel being thrombosed and closely incorporated with the sac of the aneurysm. Another point he mentioned was the importance of keeping as close as possible to the sac of the aneurysm when dissecting it out, and that this step was facilitated by laying the sac freely open as had been done here. He also thought that securing any vessels as they arose from the sac of the aneurysm and ligaturing them before division saved trouble in subsequently arresting the hæmorrhage. After an operation of this kind, when the tourniquet has been removed, there is, he said, always considerable oozing from a number of small vessels, and it is important not to close the wound until this has subsided; on that account, after all the vessels had been tied the wound was packed with swabs, and pressure kept up for a few minutes; after removal of the swabs the edges of the incision were brought together by a continuous suture and a drainage tube introduced; he said it was desirable to use a tube in these cases: first, because of the size of the cavity left; secondly, on account of the unyielding nature of the structures bounding the popliteal space; thirdly, because of the amount of oozing likely to occur. The subsequent treatment would consist in the tube being removed on the third day and the stitches taken out at the end of a fortnight. The limb had been put on a splint in a position of slight flexion for the first few days, mainly to avoid any motion caused by the possible struggling of the patient on recovering from the anæsthetic; it would subsequently be placed between sandbags.

The wound healed by first intention; the anastomotic circulation was good. The patient's temperature continued above normal, but on the whole it remained lower than before the operation, and the general condition of the man is now, three weeks after operation, much improved.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 1, 1902.

THE USE OF CHLOROFORM DURING LABOUR.

In spite of the courageous example set by the late Sir James Y. Simpson, when he had recourse to what French obstetricians ironically called *chloroforme à la Reine*, practitioners have looked askance at the use of chloroform as a routine measure during labour, some, no doubt, because the induction of partial anæsthesia adds considerably to their responsibility and trouble of obstetrical work, already, it may be urged, quite sufficient in their way, others because they have allowed themselves to be influenced by the teaching of the Continental school of obstetricians who have consistently condemned its use under ordinary circumstances on the ground that chloroform-narcosis hinders uterine contraction and thus predisposes to post-partum hæmorrhage. In a recent communication, Dr. T. W. Parkinson, of London, advances a plea for the more general recourse to the drug, which he defends against the insinuations and accusations of which it has been the object for so many years. As a matter of fact there is very little trustworthy clinical evidence in support of the allegation that chloroform, when properly administered, in any way predisposes to post-partum hæmorrhage. French investigators, it is true, affirm, as the result of long and careful observation, that the uterine contractions really are diminished in number and intensity in direct proportion to the amount of the drug inhaled, but the reduction in the expulsive force is, in all probability, due merely to paresis of the abdominal muscles and not to any interference with the uterine muscle. Moreover, in normal labour, it is open to question whether a slight diminution in the contractions may not be of direct service by reducing the risks of rupture of the perineum, &c. Be this as it may, Dr. Parkinson affirms that he has never seen a case in which post-partum hæmorrhage was associated with the rational administration of chloroform, and this, we fancy, would be the experience of practitioners who are in the habit of using chloroform in their obstetric practice. It is an invaluable means of obtaining relaxation of a rigid os uteri, a condition which so commonly protracts labour, and this effect is produced with comparatively small doses. It is not denied that if chloroform anæsthesia be pushed to a surgical degree cessation of the pains may be brought about, although it is often observed that the rest thus afforded to the jaded uterus is followed by the resumption, after an interval, of steady regular contraction. It is a mistake to postpone chloroformisation until quite the end of labour, if for no other reason than that its maximum benefits are thereby frustrated. The arguments in favour of the routine use of chloroform are based on its rational administration. It should not be given too early, that is to say, while the pains are still bearable, and under ordinary circumstances it is unnecessary at any stage to push anæsthesia to the surgical degree. It is particularly in the obstetrical use of chloroform that the advantages of a regulating inhaler are most manifest. A fraction of a drop of the drug can be pumped into the mask with every inspiration, and with this inhaler the proportion of chloroform vapour can be increased or diminished with the greatest ease and certainty. Few women whose pangs have been assuaged and rendered tolerable by the rational administration of chloroform would ever consent to face the ordeal without it. Should it become necessary to apply the forceps or perform any other obstetrical operation, the anæsthesia can be forthwith increased without any fuss and without exciting apprehension on the part of the patient, and in the event of a perineal rupture the damage can be made good before consciousness is allowed to return. We should require very cogent and well-supported reasons to induce us deliberately to withhold these advantages from suffering women, and so far it does not appear that valid arguments have been advanced against habitual resort thereto.

RADIO-ACTIVITY,

Radio-activity is one of the characteristic and engrossing physical phenomena of the opening years of the twentieth century. Radiations pervade the heavens above; they traverse the earth beneath; and they permeate the waters under the earth. "Space is all aquiver with waves of radiant energy, ranging in length from many feet to a size infinitesimally small. To only a few of these are our bodily senses fitted to correspond, or our mechanisms to detect. Waves of radiant energy constitute what has been called 'the harp of life.' We vibrate in sympathy with a few strings here and there—with the X-rays, actinic waves, light waves, heat waves, in the treble, and the huge electro-magnetic waves of Hertz and Marconi and the grand air waves of sound in the bass; but there are great spaces, numberless strings, an infinity of possible radiations, to which we are deaf. Some day, a thousand years hence, we shall know the full sweep of this magnificent harmony, and with it we shall vibrate in accord with the Master Musician of it all." Thus spoke Professor Robert Kennedy Duncan of the "Becquerel rays," whose vibrations have recently agitated the intellectual media of all the foremost communities of civilisation. Becquerel's discovery of the rays which now so much agitate the collective thought of the scientific world owes its original inspiration to that of the X-rays of Professor Röntgen. The metal uranium and the salts thereof have long formed a special domain, which has proved a most fruitful hunting-ground for the researches of investigators in the department of physical optics. While experimenting with one of those compounds—the double sulphate of uranium and potassium—Professor Becquerel made the startling discovery that its proximity affected a photographic plate through a fold of black paper, and a sheet of metallic aluminum, copper, &c. He also soon found that its vicinity rapidly discharged the gold leaves of an electroscope—at some distance. Here was a new light: unexpectedly shed on one of the darkest nooks of the domain of physical science. The last-mentioned effect was necessarily through the medium of the air; and further research showed that "metallic uranium was about three and a-half times more active in *ionising* air than is the double sulphate of uranium and potassium." At about the same date M. Niewenglowski obtained a corresponding photographic impression with calcium sulphide; and M. Troost with hexagonal blende. In 1898, M. Schmidt and Mdme. Curie observed—independently of one another—that thorium possesses analogous properties. But the further investigations of the latter accomplished lady revealed the fact that there are certain minerals more active than any of the agents we have named. The greatest interest was soon concentrated on the mysterious properties of *pitchblende*. From this peculiar mineral they separated an active bismuth—possibly a new element—to which, in honour of Mdme. Curie, who is a Polish lady by birth, they gave the name of *polonim*. They shortly afterwards separated an active barium, which contained a new element, *radium*. This element has not been obtained in the pure state, but its chloride, which has been made and studied with elaborate care, has been found to be possessed of wonderful properties indeed. It is, of itself, luminous; and is, accordingly, able to produce its own photograph; its presence—by radiation—produces various chemical reactions; it colours glass; it converts oxygen into ozone; changes yellow phosphorus to red; ionises not only gases but liquids—such as petroleum and liquid air; and insulates solid bodies, such as paraffin—developing in the latter substance a residual conductivity which lasts a long time after the direct influence of the radium has been removed. And a further property is announced which will more especially interest the pathologist: the proximity of radium to organic tissues causes deep burns, analogous to, and much more severe than, those produced by the X-rays of Röntgen. Another characteristic peculiarity of those Becquerel rays has since been established by further experimentation: that their action is influenced only by the density of the substance which is exposed to their penetrating power. The Becquerel rays have been shown, on further investigation, to consist of a mixture of two kinds of emanations—one deviated and the other not deviated by the influence of a magnet. And the final result obtained is that: "The properties of the deviable Becquerel rays are identical with those of the X-rays of Röntgen."

CONSUMPTION AMONG THE INSANE.

For some time alienists have realised that consumption was becoming exceptionally prevalent among asylum inmates. In 1899, Dr. F. G. Crookshank and Dr. Eric France clearly showed that pulmonary tuberculosis occurred in cases of mental derangement to an extent which was evidently largely determined by the non-hygienic conditions of life in the large institutions in which these unfortunates were of necessity confined. The matter was discussed by the Medico-Psychological Association, and in 1890 a Tuberculosis Committee was appointed to gather trustworthy evidence. Meanwhile attention has been directed to the matter by various writers. Sir James Crichton-Browne, at last year's memorable Tuberculosis Congress, presented the valuable evidence which had been collected by Dr. Frederick Hearder, at the West Riding Asylum. Investigation of 500 consecutive post-mortems on persons from fifteen years of age and upwards showed that in 170, that is to say, in 39·2 per cent., tuberculous lesions existed. In ninety-three cases, or in 18·6 per cent., there was active tubercle; and in 103 cases, or 20·6 per cent., there was obsolete tubercle. The recently published report of the Medico-Psychological Association amply confirms the worst fears, and proves, without shadow of doubt, that pulmonary tuberculosis is prevalent in our public asylums to an extent which calls for urgent measures A very large number of these cases have acquired the disease after admission to the asylum. The special causes for this increased prevalence of phthisis in asylums seems to be overcrowding, with consequent insufficient day, and especially night, cubic space per patient; insufficiency of hours in the open air; defects in ventilation and heating; uncleanly habits; and faults in dietary. The Committee suggest measures for the rectification of this alarming state of affairs, and urge the necessity for the early diagnosis of phthisis in asylum cases. They recommend the adoption of such means of prevention as—isolation of all phthisical cases, limiting the size of future asylums, checking overcrowding, increased day and night cubic space, reduction of the number of beds in dormitories, increased and more thorough natural ventilation per patient, the greatest care to prevent the spread of the disease by promiscuous spitting, and a careful supervision of dietary. But perhaps the most important suggestion is that properly constructed and suitable hospitals and sanatoria be provided and equipped with adequate and suitable surroundings for the isolation of these cases and their treatment on the most modern lines. And failing such special hospitals or sanatoria, it is recommended that temporary isolation hospitals or special wards and airing courts be set apart for this purpose. The matter is one of pressing importance, and we trust no time will be lost in facing the problem.

Notes on Current Topics.

Contract Practice in Cambridgeshire.

THE movement in favour of a modification of existing terms of club medical practice is bound to spread throughout the country. The conditions which obtained when practitioners methodically employed unqualified assistants, on whom devolved the major part of the work, have been altogether changed by recent events and the general rise in wages, corresponding to a similar rise in the cost of living, renders it necessary to reconsider the terms under which contract medical attendance has been carried on for the last half-century. The question has just entered upon an acute phase at Chatteris, Cambridgeshire, where the club doctors have asked that the terms be raised from four shillings per head per annum for adults and three shillings for children to six shillings and four shillings respectively. A "large and enthusiastic meeting," says the *Cambridgeshire Times*, was held last week to consider the matter, with the result that the majority voted against any departure from the old conditions, although they were willing to pay a fee of two shillings for the examination of candidates for membership and one shilling per tooth-extraction. It was pointed out how unreasonable it was to expect medical men to travel distances which might reach three miles over often impassable roads for the existing four shillings a year, but a motion in favour of the doctors' contention was defeated by an overwhelming majority. It remains to be seen whether the spirit of cohesion between medical men, which has certainly grown up within the last few years, will suffice to prevent any outsider coming in and frustrating this very legitimate movement. The general feeling in the profession is unquestionably favourable to concerted pressure being brought to bear to improve the conditions of medical practice all round, and we confidently believe that no member of the profession will deliberately reinforce the resistance of those who evince a determination to refuse even the most moderate concession in this direction.

The Cytology of the Blood in Malignant Disease.

IN seeking to bring light into the dark recesses of those processes which constitute "cancerous" disease every illuminant must be pressed into the service. It is natural, therefore, that pathologists should seek to find changes in the blood which might further advance in solving what, hitherto, has proved insoluble. And yet, in spite of much work, we are still asking: 'Has the mere presence of a malignant growth any direct influence upon the blood of the patient suffering from cancer?" and "Are the alterations found in the blood-cells in many cases of cancerous cachexia of a specific nature?" or "Is there any evidence to be obtained from the examination of the blood in cancer that can be considered of any diagnostic value?" Dr Cecil Price-Jones has sought to answer these questions in the recently issued first volume of the Reports from the Cancer Research Laboratories of the Middlesex Hospital. His conclusions, it must be at once admitted, are not such as to encourage much hope from this line of research. The results are very variable, and in no case can any single examination be regarded as of the slightest diagnostic value. Taking, however, a group of cases, it would seem that there is generally a gradual increase in the percentage of polymorphonuclear cells, associated with a corresponding diminution of lymphocytes; in other words, a gradual increase of granular leucocytes at the expense of the non-granular, and this quite independently of the presence or not of leucocytosis. Another feature which also is not by any means a constant one, but which occurs in a sufficient number of examinations to make it notable, is the increased percentage over the now accepted normal of the large mononuclear hyaline cells. The number of red cells and hæmoglobin are diminished in cachectic cases, and when there has been rapid or great loss of flesh. Poikilocytosis, and variability of red cell diameter, is another notable feature, and a condition which in many cases is observed in quite early stages, where red cell count, and hæmoglobin index and leucocyte percentage hardly vary from the normal.

DR. W. H. WELCH, Professor of Pathology in Johns Hopkins University, Baltimore, will deliver the Huxley Lecture this (Wednesday) afternoon, on "Immunity."

The Perils of Intoxication.

The man in the street, in spite of the general spread of ambulance knowledge, persists in treating drunkenness as a jocose and trifling matter. His hardihood is on a par with that of the American engineer who sits on the safety-valve of the boilers in order to get top speed out of an unfortunate steamer. As medical journalists are never tired of pointing out, an individual in a state of comatose intoxication is really exposed to peril and jeopardy of no slight degree. The main risk arises, naturally enough, from the fall of temperature induced in the later stages of acute alcoholic poisoning. It is one of the sad yet common tragedies of hospital life for such a patient to be carried into the wards insensible and to die a few days later from pneumonia without having regained consciousness. Had the dangers of drunkenness been even faintly realised by a certain photographer of Dudley, he would have been spared a serious error of judgment a few days ago, when a lady fell out of her chair on to the floor after having her photograph taken. Under the impression that the unfortunate woman was intoxicated he did not send for medical assistance until nearly three hours had elapsed. When the medical man arrived he found it to be a case of apoplexy, and the patient died shortly afterwards without regaining consciousness. The photographer is to be blamed, not because he failed to recognise apoplexy, although that would be known to any ambulance student of average intelligence, but because he did not know the necessity of medical aid to drunken persons. In any case, if he had called in a medical man he would have been relieved of a great amount of responsibility and subsequent trouble.

Pauper Lunatics and their Attendants.

There is reason to think, judging from reports that appear in the public newspapers from time to time, that the lunatic pauper service of the metropolis is in need of a thorough overhauling. The process of investigation applied by the Southwark Board of Guardians has resulted in considerable changes, from which the defects of the former system may pretty safely be inferred. Some time ago a complaint was made by a woman to the Local Government Board on the ground of the ill-treatment of her husband whilst an inmate of the lunatic ward at St. George's Workhouse, Southwark. The central authority referred the matter to the Workhouse Committee for inquiry and report. The subsequent report admitted that certain bruises complained of by the wife were sustained by her husband whilst in the lunatic ward, "but whether from his own violence or not is not quite clear." Nor was the origin of bruises found upon two other lunatic inmates any clearer. The Committee reported disobedience to orders on the part of one attendant, who had been requested to resign. Another attendant had left. The Committee were of opinion that the new attendants should have greater experience in the care of lunatics, and therefore recommended that those officers be non-resident, with wages at the rate of 32s. per week, rising to 35s. This is a step in the right direction, although the rate of wages is not high when the skilled and responsible nature of the services required is taken into consideration. It is to be hoped that the Whitehall authorities will insist on the Southwark Guardians providing a sufficient number of lunatic attendants.

When to Operate in Appendicitis.

The question of when to operate in appendicitis is still a moot point among surgeons. Hence the general practitioner who has advised a definite course, either of action or of inaction, is apt to find his opinion opposed to that of the consulting surgeon. In other words, no general rule has yet been established as to the best method of procedure in the interests of a patient suffering from active inflammation of the appendix. For all that the general trend of medical authority appears to be pointing every year more and more in the direction of immediate operation in all cases, no matter how acute the recurrence or the onset of symptoms in a first attack. There is much to be said in favour of this attitude when the comparative safety of modern abdominal surgery is taken into consideration. There can be no doubt that delay has been the cause of many more deaths from appendicitis than those that have followed upon early operative interference. At the recent Belgian Congress of Surgeons at Brussels the subject was ably discussed by Professor Sonnenberg, of Berlin. It is worthy of note as a sign of the times that most of the speakers at the subsequent discussion were in favour of immediate operation in all cases. As surgical experience accumulates, there is little doubt that this *questio vexata* will be settled in a definite and satisfactory manner. Other points of equal obscurity in relation to the malady have been cleared up with the precision and rapidity that characterises scientific surgery at the end of the nineteenth century.

Glanders and Rabies at the Cape.

The evils of war are far-reaching and disastrous, even when waged under modern civilised conditions. The three years' war in South Africa has been attended by the usual wholesale distribution of camp infections in the shape of dysentery and enteric fever. A fresh danger, moreover, has recently been added in the shape of glanders and rabies, which are reported to have been spread all over South Africa. The glanders is said to have been distributed through the sale of horses by the Remounts Department. The question naturally arises, first, how the Remounts Department came to have glandered horses in their possession, and, secondly, why such animals were sold by the Department. In any properly organised official department for the provision of horses for Army use we have no hesitation in saying that no animal should be approved until its freedom from glanders had been demonstrated by the Mallein test. The scandals in connection with the supply of horses to the British Army during the late campaign read like one of the romances written by the late lamented Baron Munchausen. That our soldiers' lives should have been sacrificed to the incompetence or corruption of contractors is serious enough without the additional loss that will be entailed by the wholesale distribution of glandered horses. In a young country it is a thousand times easier to introduce infection than to eradicate it later when administrative methods are more complete.

The Manchester Infirmary Muddle.

Cottonopolis occupies a foremost position in the mercantile world, but concerning the rebuilding of its antiquated infirmary it has long been conspicuous by its remarkable ineptitude. For a quarter of a century the question of providing an adequate institution for the care of Manchester's sick poor, and a suitable field for clinical instruction, has been discussed and nothing has resulted, as is clearly shown by our Manchester correspondent. The Board of Management have at last realised, what has been only too evident to most citizens for many a long day, that they are quite unfit to direct the affairs of a large hospital in accordance with modern requirements, and almost all the members have tendered their resignation. For years there has been warfare between the Board and the Trustees. A number of the leading Trustees have recently met and declared their determination to carry this troublesome matter to a reasonable conclusion. They have indicated their line of action by adopting the following resolution:—"That the object of the Committee be to recommend the election of a new Board in order to carry out the following policy: Not to permit rebuilding on Piccadilly site, and to build without delay at Stanley Grove, unless a better site is offered." We sincerely trust that Manchester men will lose no more time, but at once proceed to erect hospital buildings worthy of their city and its justly distinguished medical school.

A Popular View of Sanitary Science.

In the course of some articles which have just appeared in *The Times* on municipal trading the writer institutes a curious comparison between the administrative requirements of the Public Health Acts, and those of other municipal undertakings. He says, for instance, that it is absurd to expect "labourers, carriage-wheel greasers, and others of the same type," to pretend to manage such a costly undertaking as an electric lighting department, though "on questions of public health and similar phases of local government their judgment might be as good as that of anyone else." Obviously, even a sound lawyer might be at a loss to personally superintend an electric lighting plant, but municipal councillors are not expected to do anything of the kind. In the same way the average councillor would be very embarrassed if asked to advise as to the means to be employed to promote public health, or to apply them himself, but here again he is only required to obtain skilled advice and to authorise its application. Fully as much technical knowledge is required in the one case as in the other, and this careless remark merely shows what small importance outsiders attach to the most weighty problem of modern times, a problem which concerns interests far and away beyond that of a mere question of street lighting. Yet if municipal councillors cannot be trusted to administer the laws concerning the public health, what can they be trusted to do? Following the same line of argument the Public Health Service would be described as an unremunerative investment, one of the kind against which municipalities are warned. To the dispassionate observer it would seem that the supply of light and water and public convenience in the matter of street management are pre-eminently things which naturally fall into the municipal domain.

The Epidemic at Derby.

From the point of view of the clinical bacteriologist, the curious epidemic that has resulted from the eating of certain pork pies at Derby is more than usually interesting. The illness was regarded at first as a series of cases of ptomaine poisoning, but Professor Delépine's interim report shows that this is far from the truth, though the lay newspapers still disregard the correction. The fact is that it was an acute specific disease, parallel with typhoid fever in many points, and caused by a bacillus of the coli group. The infection was conveyed in the pork, which seems to have acted as the medium of a virulent culture of the organism, and the same organism has been isolated from the pork, from the spleen, blood, bile, and intestines of a fatal case of the disease, from the same parts of animals fed on the infected pork, and from the blood of animals inoculated with a pure culture. The case is completely established by a definite serum, reaction being given with the blood of other patients who partook of the pork pies, while no reaction took place with healthy or typhoid blood. How the pork was originally infected is not yet made clear. It was thought until recently that the coli group of bacteria were not actively pathogenic except in the occasional formation of pus, but lately, as we have noticed, several cases of so-called "paratyphoid" fever have been traced to their action, and now we have to add an acute disease of a very dangerous type.

The Illness of the Marquis of Salisbury.

We learn that the Marquis of Salisbury has so far improved that his removal from Lucerne, it is hoped, may shortly be practicable. The venerable statesman has suffered for years from intestinal paresis, the effects whereof have been mitigated by massage and appropriate measures. The condition is one which entails an ever-present risk of intestinal obstruction, with its concomitant dangers. The advanced age and obesity of the patient add to the difficulty of maintaining the functions in a satisfactory state of activity, hence the anxiety which is felt at the slightest irregularity.

The Reported Scarlet Fever Cure.

The imagination of the newspaper reading world has been raised more or less to fever pitch by the announced discovery of a serum cure for scarlet fever. So far as can be gathered the rumour has arisen from the premature publication of some therapeutic investigations and experiments carried out by Dr. Moser, Assistant Physician to the St. Anne's Hospital for Children in Vienna. A subject of the kind can be solved only as the result of prolonged and extended scientific research of a most patient and thorough character. That the public newspapers should get hold of special information of the kind in its imperfect stages is perhaps hardly to be wondered at when we consider the accessibility and openness of medical journals and the ubiquitous curiosity of the modern lay journalist in search of sensational "copy." In the present case the mischief of premature publication has been done, and it is to be presumed that Dr. Moser is the unhappy victim of the lurid publicity which the newspaper press apparently delights in bestowing upon bashful and reluctant professors. That a cure for scarlet fever will one day be found is a firmly-grounded canon of belief with most medical men. That the specific remedy will cure in the form of a curative serum is another article of almost, if not quite, equally accepted faith. It would be a thousand pities, however, were the search for this holy grail sullied by the faintest breath of suspicion that personal aggrandisement formed part of the prize awaiting the hero of the fight.

Coroners and Unqualified Practitioners.

The defective state of the Medical Acts with regard to the control of irregular medical practice renders it most desirable for the profession to keep itself informed of all safeguards that may be in any degree available. Of such regulating agencies the chief, undoubtedly, are in the hands of the registrars of deaths and of the coroners. These public officials in the discharge of their duties have abundant opportunities of calling attention to the proceedings of irregular medical practitioners. In the case of the registrars of deaths it is to be feared that they are not in all cases impressed with an adequate view of their duty and responsibility in the matter of certificates. At the same time it may be freely admitted that of late years great improvement has taken place in the official attitude towards questionable certificates. Coroners have done an immense amount of service to the community by calling attention to the evils of unqualified practice. Quite recently a pretender of that kidney has been prosecuted at the instance of a coroner for perjury committed at an inquest. A medical man is not entitled to give evidence at an inquest unless he is registered as well as medically qualified. In the case mentioned he appears to have been neither the one nor the other. It may perhaps be hinted that coroners would do well to ascertain in every instance whether the name of a medical witness actually appears upon the *Register*.

The Personation Peril.

An extraordinary case of alleged personation now engaging the attention of a London magistrate illustrates the glaring defects of our present system of medical registration. A man named Herring stands accused of perjury for evidence given at an inquest in which he posed as a qualified and registered medical practitioner. His name is not to be found on the *Register*, neither is that of either of the gentlemen under whose names he practised, at any rate, in the London list. Should the allegations of the prosecution be true the accused will have achieved a record in the direction of impudent personation. There appears to be no doubt that he carried on practice in a suburb of the Metropolis under the united names of Hoffmeister and Dobie. As the matter is still *sub judice*, it is not permissible at present to exceed a brief statement of facts. At the same time we feel justified in drawing attention to another point brought out in evidence, namely, the attitude of a neighbouring general practitioner who a year or more ago refused to meet the accused in consultation. Presumably his refusal was based upon the knowledge of the illegal nature of Herring's proceedings, which he apparently took no steps to expose. Perhaps some more satisfactory explanation may be forthcoming, for it is impossible to conceive that immediate action would not have been taken by the Medical Defence Union or other responsible body had their attention been called to the matter. In any case, whether the present prosecution be established or not, the possibility of such an occurrence as that alleged to have taken place more than emphasises the ridiculous nature of a professional registration which is purely voluntary.

A Latter-day Faith Cure.

The saving grace of a little faith is nowadays a well-recognised weapon in the therapeutic armoury. It enters largely into the framework of not a few methods advocated by followers of orthodox medicine, to say nothing of the multifarious devices adopted by the quack and the charlatan. Nor, in all sober seriousness, would it be possible for the candid student of scientific medicine to exclude the psychological element from his reckoning. In faith, and faith alone, lies the value of the Mattei so-called "cure" of cancer, inasmuch as the matter-of-fact chemical analysts have reported that the remedies consist of water—"only that and nothing more." Yet many worthy folk—among them that gifted journalist, Mr. Stead — have been found to maintain the positive value of the Mattei remedies against all and sundry. A similar faith in plain water appears to be shared by certain of Mr. Stead's countrymen, if we may judge from the recent revelations in a London police-court. The Aldgate pump, as all the world knows, is a famous, and, indeed, historical feature of the East End, where its waters have long enjoyed a reputation for healing virtue. To this day people come from a distance, especially on Sunday morning, and carry away this precious medicinal water in bottles. It appears, however, that some twenty years ago the well was closed, for reasons that are sufficiently obvious, and ever since the pump has been fed by a tank, which has in turn been supplied by water from the New River. This incident affords an amusing and delightful illustration of the psychology of "faith" cures.

The Irish Giant.

The skeleton of the Irish Giant, which was shown by Professor Cunningham, F.R.S., at the recent meeting of the British Association for the Advancement of Science in Belfast, is a sadly convincing proof of the inaccuracy of the old folk-lore tales of magnificent giants. Cornelius Magrath, who, in his life, was "the only representative in the world of the ancient and magnificent giants" of Ireland, and who possessed "the truest and best proportioned figure ever seen," has after his death been pronounced to have been the result of acromegaly, and, according to Professor Cunningham, nearly blind, knock-kneed, and of a decrepit appearance. The Irish Giant was 7ft. 5in. in height; he was born in Tipperary in 1736, and died in 1760, after having been exhibited in most of the important cities of Europe. Apparently his excessive height was due to the effect of acromegaly occurring before the consolidation of the skeleton, whereas the more common form of this disease usually occurs after such consolidation has taken place, and when, consequently, no increase in stature results.

The Etiology of Salmon Disease.

A most interesting paper was read at the recent meeting of the British Science Association by Mr. J. Hume Patterson, Assistant Bacteriologist to the Corporation of Glasgow, on the cause of the so-called salmon disease. Up to the present investigators into the condition have considered it to be due to invasion by the *fungus saprolegnia ferax*. Mr. Patterson, on the other hand, has come to the conclusion that this is not so, but that the disease is due to a liquefying bacillus, which he terms the *bacillus salmo pestis*, and that the notion that the former fungus was the cause arose from the fact that the latter will only grow on salmon previously infected by the bacillus and consequently are only met with in cases of salmon disease. Mr. Patterson's experiments also proved that salmon disease was not contracted when the skin of the fish was in a healthy state, but that infection could readily occur if the skin had become rubbed or scratched by scraping against sand or rocks. All fish related to salmon were more susceptible to the disease than others of a different genus. Professor Howes, the President of the Section, in discussing Mr. Patterson's paper, pointed out that his results might have an interest for investigators into the causes of cancer, inasmuch as in that disease there was an antecedent morbid state associated with a pathological organism. This is, however, equally the case in the majority of morbid conditions, as there must always be a suitable soil as well as the seed of the disease. Consequently, unless Mr. Patterson's researches elucidate some more important resemblance to the etiology of cancer, we fear they will advance that problem but little.

Bad Language in the Streets.

Unquestionably it would be an excellent thing if means could be found to restrict the use of obscene language in public thoroughfares, and we do not despair of progress in this direction. Unfortunately such language is made use of to a deplorable extent by mere children, and this aspect of the question was recently discussed by the Liverpool magistrates, who decided to instruct the Chief Constable to enforce more strictly the provisions of the Liverpool Improvement Act, "with the object of bringing to the better knowledge of such children the meaning of the words they so thoughtlessly employ." With every respect for the worthy intention of the magistrates we think the best way of bringing the meaning home to the delinquents would be by the routine application of the birch. Is it intended that the Chief Constable shall explain the meaning of the terms to the children, or is he to depute the function to a subordinate official? In any event the task will be a very delicate one—one moreover, which may fall short of the desired result.

The Health of Mr. Roosevelt.

There appears to be singular lack of precision in the information which reaches the press concerning the health of the President of the United States. The truth is that the injury which Mr. Roosevelt received in the carriage accident a few weeks since had for effect to determine some localised periosteitis of the tibia, which culminated, as is so often the case, in suppuration. At first he ignored the pain and swelling, and it was not until there was a rise of temperature that he allowed his medical advisers to intervene. By that time the periosteum had been stripped off the bone for a short distance, and, as recent events show, the interference thus caused with the local blood supply led to necrosis. The further course of the troublesome injury will depend upon the measures adopted. If the necrosed bone be left to exfoliate this process will, of course, take some time, leaving the patient exposed to the risk of septic complications, against which the strictest precautions are not always effectual. It may be, however, that his medical advisers will persuade him to allow the piece of bone to be removed surgically, in which case there is no obvious reason why cure should not be rapid. We may be sure that the treatment which the President receives will be that indicated by the special circumstances of the case, but while a lesion of this kind can never be described as absolutely without risk, there is in reality little ground for anxiety.

The General Medical Council Election.

The polling for the election of a direct representative on the General Medical Council has resulted in the return of Sir Victor Horsley by a majority of 4,567, the total number of votes in his favour being 7,672, as compared with 3,105 for Mr. Joseph Smith. We congratulate Sir Victor Horsley on his re-election, which makes for efficiency and reform. At the same time the measure of support accorded to Mr. Joseph Smith marks him out as a "likely" candidate at a future election, when electors will not have to choose between him and Sir Victor Horsley.

PERSONAL.

Mr. F. Danford Thomas has been appointed Deputy Coroner for the City of London.

Colonel W. Briggs Allin, R.A.M.C., has been appointed Principal Medical Officer of Cape Colony.

Professor Sims Woodhead assisted at the opening ceremony of the new Bacteriological Institute at Copenhagen on September 9th.

Dr. David Ferrier, F.R.S., will deliver the Harveian oration before the Royal College of Physicians in London on October 18th, at 4 p.m.

Mr. C. F. Myers Ward, Professor of Physiology at University College, Sheffield, has been appointed Lecturer in Physiology at the Charing Cross Hospital School of Medicine.

Professor Erb, of Heidelberg, will be the guest of the evening at a dinner which is announced to be given at the Trocadero Restaurant on Saturday, October 11th, with Dr. Donald W. C. Hood in the chair.

Lieutenant-Colonel Clery, R.A.M.C., formerly Senior Medical Officer at Cambridge Hospital, Aldershot, has been appointed Principal Medical Officer in the Transvaal and Orange River Colony.

Miss Emma Moleo, a Jewish lady-doctor of Tunis, has started practice in that city, where she will practise in association with Miss Gordon, who for some years past has been the only lady-doctor there.

Dr. Priestley, the Medical Officer of Health for Lambeth, has been voted an honorarium of a hundred guineas in recognition of his services in connection with the epidemic of small-pox in that borough.

A memorial to the memory of the late Dr. D. Ramsey, of Ringstead, was unveiled last week "in testimony of the genial and sympathetic manner in which, for thirteen years, he had skilfully discharged the duties of his calling."

Mr. Rickard Lloyd, President of the West London Medico-Chirurgical Society, will read the opening address on "The Field of View of the Anæsthetist" at the Society's meeting on Friday, October 3rd, at the West London Hospital.

Mr. Edmund Owen will be presented with the testimonial subscribed by past and present students of St. Mary's Hospital on the occasion of the annual dinner which will be held at the Whitehall Rooms, Hotel Metropole, on Friday next (October 3rd).

Dr. Ernest White, the resident physician and superintendent of the City of London Asylum, and the Professor of Psychological Medicine at King's College, London, has been elected the president of the Medico-Psychological Association of Great Britain and Ireland for 1903-4.

Dr. Lionel P. Shadbolt, of Liverpool, distinguished himself a few days since by an act of gallantry which deserves mention. He jumped overboard from the ferry-steamer after a passenger who had fallen overboard, and, in spite of a strong ebb-tide, he succeeded in effecting his rescue, thanks to his prowess as a swimmer. The act is one which merits public recognition.

Special Correspondence.

MANCHESTER.

[from our own correspondent.]

The Infirmary Question.

It will be remembered that a few weeks ago the Board of Management submitted to the Trustees a scheme for rebuilding the Manchester Royal Infirmary on the present site in the centre of the town; and further, that this scheme was thrown out by a great majority of the Trustees. At a meeting held last week it was announced that all except two members of the Board have resigned. The general policy of the Board, apart from the rebuilding question, has always met with fairly general approval, and it would, of course, be very difficult for an entirely new body of men to take up the management of the institution. It is, therefore, understood that a number of those who have resigned will allow themselves to be re-elected by the Trustees, together with some "new blood." The fresh Board so constituted will probably at once proceed with a scheme for a new infirmary on a new site some little distance from the centre of the town and near to the Owens College.

It is obvious that some active work must have been done among the Trustees of late to bring about such results as the defeat of the Board and the throwing out of its scheme. The party who were able to do this will doubtless be ready with some fairly definite proposals. It is certain that these will not include the demand from the Corporation of £400,000 for the site of the present Infirmary, nor the sale of the site to anyone who might be willing to buy it for business purposes. Something more feasible than either of these ideas can be devised by those business-like Trustees who are taking the matter in hand. Some of these gentlemen, by the way, are not perfectly contented with the present management of the charity, and the new brooms on the Board may find room for some sweeping in the old building before they begin the erection of a new one. They will be supported by the representatives of the Medical Board, who now sit on the Board of Management.

BELFAST.

[from our own correspondent.]

Consumption in Belfast.

Public attention in this city is happily being directed at present to the high death-rate from tuberculosis, and a vigorous controversy regarding it is going on in the daily press. This controversy rose from a paper read at the late meeting of the British Association in Belfast by Mr. Robert Brown, the Hon. Sec. of the local branch of the Anti-Tuberculosis Society.

The Medical Superintendent Officer of Health, Dr. Whitaker, has given his views on the subject. He pointed out that municipal authorities possess no power to enforce compulsory notification of the disease, and in only one large town—Liverpool—is voluntary notification adopted on an extensive scale. After referring to the death-rates in Liverpool, Manchester, Bradford, Salford, Preston, Glasgow, and Paisley, he declared that, all things considered, he was astonished that the death-rate from consumption in Belfast was not higher than it was. He attributed the prevalence of consumption to the situation of the city, and said "we can do nothing in Belfast till we get compulsory notification." When asked if he agreed that the higher death-rate in Belfast was due to defective sanitary arrangements, and the lower mortality in English and Scotch towns was to be attributed to superior sanitation, he replied, "I do not. The difference in the death-rate, in my opinion, is to be accounted for by the different climatic conditions and conditions of employment among a very large section of our population Among the conditions he puts the fewness of the holidays taken by the working classes in Belfast, and, as regards Ireland generally, the fact that the people are neither so well fed nor well clothed as in England and Scotland. Mr. Brown has promised a further paper in which he will give fuller particulars as to the shortcomings of Belfast, which he did not wish to emphasise before our visitors, so no doubt more will be heard of the matter. Whichever may prove right, the impartial man cannot but rejoice that public attention should be called to this great evil.

North of Ireland Branch of the British Medical Association.

The new constitution of the Association has rendered necessary great changes in its branches, and a circular has just been issued to the members of this Branch giving particulars of the proposed changes in it. The plan, in brief outline, is as follows:—The Branch will consist of the province of Ulster, and will be known as the Ulster Branch. The four general meetings each year will be held, two in Belfast, one in Derry, and one elsewhere. Eight divisions of the Branch will be formed; such as do not rise to the height of their opportunities will be attached to a neighbouring division.

Death under Anæsthesia.

An inquest was held last week by Dr. G. Danford Thomas, at Hampstead, on the body of a young woman who died while being operated upon for appendicitis. The anæsthetic used was a mixture of chloroform and ether, and its administration had ceased fifteen minutes before the collapse of the patient. This appears to be one of those cases in which death merely coincides with anæsthesia without there being any relationship of cause and effect. A verdict of death by misadventure was returned.

Waterford County and City Infirmary.

At the half yearly meeting of the Governors of the Waterford County and City Infirmary, held on Friday, September 26th, 1902, Dr. T. A. Kelleher's report was read. During the half-year 241 patients were admitted, of whom 139 were surgical cases and 82 medical ones. Of the surgical cases 25 were admitted as accidents, and 17 were admitted as urgent cases. One hundred and ten surgical cases were discharged as cured, 15 were relieved, and 3 died.

Death under Chloroform.

A domestic servant, æt. 24, died from the effects of chloroform, administered at the Royal Albert Hospital, Devonport. At the inquest it was stated that half-an-ounce of chloroform was administered in a quarter of an hour, and no further explanation of the collapse was needed. An exonerating verdict was returned.

Correspondence.

DR. RAINSBURY'S CASE.

To the Editor of The Medical Press and Circular.

Sir,—Referring to the appeal which you kindly permitted me to make through the medium of The Medical Press and Circular, I beg to enclose a list of the subscribers to the fund. Dr. Rainsbury and the Council of the Midland Medical Union desire me to express their thanks for the generous response which has been made to the appeal.

The amount of the judgment and costs is £182 6s. 2d. The donations already received amount to £55 12s. 3d.

It is hoped that further contributions will be received towards the balance of £126 13s. 11d.

Will you kindly insert the list of subscribers in the next issue of The Medical Press and Circular?

I am, Sir, yours truly,
George S. O'Rorke,
Secretary, Midland Medical Union.
Midland Medical Union,
Nottingham, September 24th, 1902.

MALARIA AND TUBERCULOSIS.

To the Editor of The Medical Press and Circular.

Sir,—The interesting article in the last issue of The Medical Press and Circular on the Anti-Mosquito Campaign brings to my mind another interesting paper published so long ago as 1840, "On the Influence of Malarial Atmosphere in the Prevention and Cure of Phthisis Pulmonalis," in which paper the writer (Horace Green, of New York) instances cases of phthisis "in an almost hopeless condition which had recovered on being sent to reside for some time at Whitehall, in Washington, Co. New York."

Of course the writer was not aware of the true cause of malarial fever, and concluded such was due altogether to "atmospheric influence" and the marshy surroundings of that town. He states "it is bounded on one side by low, marshy grounds, which are filled with pools of stagnant water, and from which during the summer months malarious exhalations are constantly arising, producing in the vicinity an abundance of cases of intermittent fever, *yet consumption is seldom or never known at Whitehall*" (italics mine).

As the true cause of malarial fever has now been discovered, it has struck me it would be an interesting experiment (if nothing else) to inoculate phthisical patients with blood taken from a case of malaria at height of the fever; or test the effect of mosquito bite, even at the risk of producing ague (which, of course, could at once be combated by quinine), and so endeavour to lessen the fearful mortality from phthisis, which is stated to cost in victims in United Kingdom alone 42,000 yearly, and in money value upwards of £1,000,000 per annum; the loss in wage-earning powers estimated at from ten to twelve millions annually.

I am, Sir, yours truly,
Alexander Duke.

Obituary.

MR. HENRY WRIGHT, M.R.C.S., J.P., OF SCARBOROUGH.

We regret to announce the sudden death from heart failure on Monday of this gentleman, who was the oldest practitioner residing in Scarborough. The event came as a surprise, and caused profound grief to many of the townsfolk, by whom he was held in great esteem. For the past fourteen years he had been a Justice of the Peace for the Borough, and on many occasions his medical knowledge was of service in cases before the Court, which he attended on the morning of his death. While seated in his chair at home in the evening he suddenly became unconscious, and passed peaceably away before medical aid could arrive, at the age of seventy-six.

DON FEDERICO RUBIO Y GALLI.

The death is announced of Spain's most distinguished surgeon, Don Federico Rubio y Galli, at the advanced age of seventy-five years, at Madrid. He was a member of the Academy of Medicine of Madrid since 1874, about which time he was made an Honorary Fellow of the Royal College of Surgeons, London. He performed his first ovariotomy in 1860, his first hysterectomy in 1861, and ablated the larynx in 1878. He was a consistent and able advocate of aseptic surgery and open-air treatment of patients.

MR. A. G. FIELD, F.R.C.S., WALLINGFORD.

We regret to announce the death of Mr. Alfred George Field, F.R.C.S., a well-known surgeon in Oxfordshire and Berkshire, who died on Monday at Quisisana, Benson, Wallingford, at the age of eighty-two. He had been surgeon of St. Mary's Hospital, Brighton, of the Royal Sea Bathing Infirmary, and of Blenheim Dispensary, and was a Fellow of the Royal Medical and Chirurgical Society. He had contributed several interesting and important articles to the professional journals.

DR. ARTHUR B. BLACKER, LONDON.

We regret to announce the death of Mr. Arthur Barry Blacker, M.D.Durh., an authority on X-rays, at 16, West Halkin Street, Belgrave Square, at the age of forty. He was a son of the late Rev. Maxwell Blacker, and studied at the Medical School of St. Thomas's Hospital. In 1886 he became a licentiate of the Royal College of Physicians, London. Four years later he took the M.D. degree at Durham, and in 1891 became a member of the Apothecaries' Society. Dr. Blacker had been assistant electrician at St. Bartholomew's Hospital, house surgeon at the West London Hospital and at the Belgrave Hospital for Children, assistant demonstrator of anatomy at the University of Durham, physician to the SS. Paul and Barnabas Dispensary, and resident physician at Mena House, Cairo. At the time of his death he was superintendent of the X-ray department of St. Thomas's Hospital, and the Hospital for Consumption, Brompton, and senior medical officer of the Royal Pimlico Dispensary. Dr. Blacker had written extensively on light as a therapeutic agent.

Pass Lists.

University of Durham.—Faculty of Medicine.

The following candidates have passed the First Examination for the Degree of Bachelor in Medicine during September:—

1. Elementary Anatomy and Biology, Chemistry and Physics: Frederick Charles Pybus, with second class honours. Pass List: Horsley Drummond, Walter Nicholas Jones, Hector Graham Gordon Mackenzie, M.A., George Robert Philipson, David Ranken.

2. Elementary Anatomy and Biology: Helen Young Campbell, Lewis Augustus Clutterbuck, L.R.C.P. and S. Ed., L.R.C.P.I., Hamilton Drummond, Camilla Lucy Heckrath, Florence Barrie Lambert, Jessie Jean Martin Morton, Jessie Margaret Murray, Norman Spedding, Eric Frushard Waddington.

3. Chemistry and Physics: Vincent Edgar Badcock, Thomas Henry Bishop, M.R.C.S., L.R.C.P., George Edward Peckett Davis, George Denholm, Neville Avory Eddlestone, John Charles Norman, Geoffrey Pybus, Richard Woodward Swayne, Lionel Langford Westrope, Frank Whitby, Thomas Leathard Wormald.

The following candidates passed the Second Examination for the Degree of Bachelor in Medicine:—Anatomy, Physiology, and Materia Medica: James Glenny Gibb, with first class honours. Honours, second class: Lillie Johnson, B.Sc., William Edward Hopkins, Arthur Alan Miller, M.R.C.S., L.R.C.P., Francis Henry Moxon. Pass List: Arthur Edward Clayton, James Henry Cooke, B.Litt., William Cowden, Hugh Boyd Cunningham, William Ernest Falconar, Arthur Beresford Jones, Cyril Claude Lavington, William Ernest Craven Lunn, Ernest Martin, Charles Duncan Relton, Oswin Shields, M.R.C.S., L.R.C.P., Richard Geoffrey Shaw Simpson, Frank Tomisman Simpson, Edward Tate, Tys Visser.

The following candidates have passed the Third Examination for the Degree of Bachelor in Medicine:—James Alexander Bennett, Henry Mounsey Braithwaite, Llewelyn Alfred Henry Bulkeley, Herbert Christal, Edgar Fletcher Edmunds, Arthur Henry Fullerton, Albert James Gilbertson, Marshall Haver, Norman Haliburton Hume, Sophia Bangham Jackson, John George Ogilby Hugh Lane, M.R.C.S., L.R.C.P., Thomas William Maddison, Aurelius Victor Maybury, Arthur Alan Miller, M.R.C.S., L.R.C.P., Stanley Robson, William Tait Sewell, Arthur Lewin Sheppard, Oswin Shields, M.R.C.S., L.R.C.P., Frederick James Strachan, Samuel George Webb, Hermann Wolfe.

Society of Apothecaries of London.

The following candidates passed during September in:—

Surgery: E. W. C. Bradfield (Section II.), D. Cotes-Preedy (Section I.), B. C. Ghosh (Section I.), E. H. Griffin (Sections I. and II.), A. T. Harvey, M. E. Martin (Sections I. and II.), E. J. Miller, G. B. S. Soper (Section I.).

Medicine: E. W. C. Bradfield (Sections I. and II.), C. R. Bradley (Section I.), J. C. S. Dunn, I. Griffith (Section II.), M. E. Martin (Section II.), C. C. Morgan (Section II.).

Forensic Medicine: E. W. C. Bradfield, C. R. Bradley, K. Heanley, C. C. Morgan, P. J. Pagonis.

Midwifery: S. Bentley, P. S. Cooke, B. C. Ghosh, H. Jacques.

The L.S.A. diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—E. W. C. Bradfield, J. C. S. Dunn, A. T. Harvey, M. E. Martin, E. J. Miller, and C. C. Morgan.

Notices to Correspondents, Short Letters, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

A STATUE TO DR. CRAWFORD W. LONG, OF ANÆSTHESIA FAME.

To the Editor of The Medical Press and Circular.

Sir,—As Crawford Williamson Long, the discoverer of general anæsthesia, was the grandson of an Ulsterman who emigrated to America in the eighteenth century, I think all Irishmen will be both interested and gratified by reading the following announcement, for a copy of which I am indebted to my friend, Dr. Landon P. Edwards, of Richmond, Virginia:—"In accordance with a special Act of the Legislature of the Commonwealth of Georgia, a statue of Dr. Crawford Williamson Long, the discoverer of general anæsthesia, will be given the first place in the Statuary Hall at Washington D.C., U.S.A."

I am, Sir, yours truly,

George Foy.

J. B. G.—We have answered your question to the best of our ability and we have nothing further to add.

A MAGISTRATE'S COURT FOR CHILDREN.

A correspondent writes:—The ordinary police-court is obviously a most unsuitable tribunal to deal with children charged with minor offences. The environment is degrading, and the average magistrate is hardly suited to deal with juvenile offenders, who require special knowledge and special methods of dealing with them. We might with advantage follow the example set at Boston, U.S A., in instituting a special court, to which all prisoners under sixteen years of age are sent.

Dr. M. R.—We cannot make any promise until we have been afforded an opportunity of inspecting the MS. We will undertake to return it if not deemed suitable.

THE SCIENTIFIC ASPECTS OF THE BACON-SHAKESPEARE CONTROVERSY.

Dr. John Knott sends us a reply to the criticism of our correspondent, George Stronach, of Edinburgh, which, though of great literary interest, is of such extreme length that we are unable to grant the space necessary for its insertion, especially as the subject is extra-medical. If the writer can compress his reply to about a column (instead of seven columns, as at present) we shall be pleased to place this space at his disposal.

Dr. J. R.—The subject is an important one, and we hope to have space for your communication and an editorial thereon in our next.

Meetings of the Societies, &c.

Friday, October 3rd.

West London Medico-Chirurgical Society.—8.30 p.m. Twenty-first Session. Opening Meeting. The Presidential Address. Mr. Rickard Lloyd: "The Field of View of the Anæsthetist."

Tuesday, October 7th.

Gresham College (Basinghall Street, E.C.).—6 p.m. Dr. E. Symes Thompson, M.D., F.R.C.P., Gresham Professor of Medicine, will commence a course of four popular lectures "On Food," to be continued on each succeeding evening at the same time and place.

Thursday, October 9th.

British Gynæcological Society (20, Hanover Square).—8 p.m. Specimens will be shown by Professor J. W. Taylor, Mr. Bowreman Jessett, and Dr. Macnaughton-Jones. Mr. Jessett will read a paper on "Some Complications arising subsequently to Cœliotomy." Professor Taylor will read a short communication on a case of "Uterus Bicornis with Rudimentary Right Horn."

Appointments.

Alexander, J. D., M.B., B.Ch., B.A.O.Dubl., Certifying Surgeon under the Factory Act for the Porthcawl District of Glamorgan.

Crowther-Smith, S. F., M.B.Lond., Certifying Surgeon under the Factory Act for the Liss District of Hants.

Dods, J. E., M B., B.S.Edin., Medical Officer at Brisbane, Queensland, Australia; Health Officer for the Port of Brisbane; and Visiting Surgeon to the Prisons at Brisbane.

Grant, J. W. G., L.R.C.P.Lond., M.R.C.S., Certifying Surgeon under the Factory Act for the Llanwrtyd Wells District of Brecon county.

Haycock, H E., L.R.C.P.Edin., M.R.C S, Certifying Surgeon under the Factory Act for the Alfreton District of Derby county.

McDonald, H., M.B., B.S.Dubl., Certifying Surgeon under the Factory Act for the Portaferry District of Co. Down.

Macnicol, R. R., M.B., B.S.Glasg., Certifying Surgeon under the Factory Act for the Taynuilt District of Argyllshire.

Morrison, J. T. J., M.A.Cantab., M.Sc.Birm., F.R.C.S.Eng., Honorary Surgeon to the Queen's Hospital, Birmingham.

Ratcliff-Gaylard, J., M.D.Brux., L.R.C.P. and S.Edin., L.F.P.S. Glasg., Medical Officer and Public Vaccinator for the St. Clement District by the Truro Board of Guardians.

Sheen, William. M.S., M.D.Lond., F.R.C.S.Eng., Honorary Surgeon to the *Hamadryad* Seamen's Hospital, Cardiff.

Soltau, A. B., M.B.Lond., Medical Officer to the Plymouth Public Dispensary.

Spencer, W., L.R.C.P. and S.Edin., Certifying Surgeon under the Factory Act for the Bolsover District of Derbyshire.

Vacancies.

County Asylum, Chester.—Third Assistant Medical Officer. Salary £160 per annum, with board (no liquors), lodging, and washing. Applications to Dr. Lawrence, County Asylum, Chester.

Croydon Union Infirmary, Mayday Road, Croydon.—Resident Assistant Medical Superintendent and Dispenser. Salary £120 per annum, increasing to £150, with apartments, rations, and washing. Application forms of the Clerk to the Guardians.

Down District Lunatic Asylum.—Junior Assistant Medical Officer, not exceeding 32 years of age and doubly qualified. Salary £100, with furnished apartments, board, washing, and attendance. (See Advt.)

Great Northern Central Hospital, Holloway.—Assistant Anæsthetist. Honorarium 10 guineas per annum. Also a Pathologist and Curator of the Museum. Salary 50 guineas per annum. Fuller particulars may be obtained on application to L. H. Glenton-Kerr, Secretary.

Guildford, Royal Surrey County Hospital.—Resident House Surgeon. Salary £100, with board, residence, and laundry. Applications to the Hon. Secretary.

Hamlet of Mile-End Old Town.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and laundry. Particulars on application to the Clerk to the Guardians.

Hospital for Consumption and Diseases of the Chest, Brompton.—Assistant Resident Medical Officer for six months. Salary £100 per annum, with board and residence. Also Resident House Physician for six months. Honorarium £25. Applications to the Secretary.

Monaghan Union.—Scotstown Dispensary District.—Medical Officer. Salary £120 per annum, with usual Vaccination and Registration Fees. The gentleman elected will also act as Medical Officer of Health at a salary of £15 per annum. Immediate application to Samuel Mitchell, Clerk of Union. (See Advt.)

Monmouthshire Asylum, Abergavenny.—Junior Assistant Medical Officer (Male). Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

New Ross Union.—Medical Officer. Salary £150 per annum, together with usual Vaccination Fees. The gentleman elected will also act as Medical Officer of Health at a salary of £15 per annum. Applications to P. A. Pope, Clerk of Union. (See Advt.)

Royal Hants County Hospital, Winchester.—House Physician. Salary £65 per annum, rising to £75, with board, residence, &c. Applications to W. M. Wilcox, Secretary.

The General Infirmary at Gloucester and the Gloucestershire Eye Institution.—House Surgeoncy. Salary £100 per annum, with board, lodging, and washing. Applications to the Secretary.

Births.

Brodie.—On Sept. 23rd, at The Hutch, Sandown, the wife of F. Carden Brodie, M.B., of a daughter (stillborn).

Eames.—On Sept. 20th at Lambecroft, Uffculme, Devon, the wife of E. S. B. Eames, M.R.C.S., L R.C.P.Lond., of a daughter.

Hayward.—On Sept. 23rd, at 65, Stert Street, Abingdon, the wife of M. Cecil Hayward, M.A., M.R.C.S., of a son.

Pearse.—On Sept. 23rd, at 110, Cathedral Road, Cardiff, the wife of Athol Pearse, M.B Cantab., of a daughter.

Swabey.—On Aug. 28th, at Shwebo, Upper Burmah, the wife of Captain Maurice Swabey, R.A.M.C., of a son.

Marriages.

Bascombe—Miller.—On Sept. 24th, at St. Peter's Church, Eltham Road, S.E., Edwin Cecil Dare Bascombe, L.R.C.P. Lond., M.R.C.S., of Saffron Walden, Essex, to Edith Marion, youngest daughter of T. Hastings-Miller, Esq., of Eltham.

Cowin—Byers. On Sept. 22nd, at Christ Church, Sunderland, Surgeon Captain Douglas H. F. Cowin, I M.S., to Ethel, daughter of William Lumsdon Byers.

Jameson Copland.—On Sept. 27th, at Holy Trinity Church, Eltham, Surgeon Robert D. Jameson, R.N., second son of Surgeon-General Jameson, C.B., K.H.S., M.D., late Director Army Medical Department, to Mabel Greene, daughter of H. S. Copland, Esq., of Eltham.

Morris—Moore.—On Sept. 20th, at All Saints' King's Bromley, Lichfield, Francis Ernest, son of the late J. Griffith Morris, M.R.C.S., of Hereford, to Emily Monica, daughter of the late Richard Bond Moore, M.D., of Wolverhampton.

Deaths.

Gubb.—On Sept. 25th, of meningitis, Edgar Sullivan, only son of Alfred S. Gubb, M.D. (Paris), of 29, Gower Street, W.C., aged 21.

Hague.—On Sept. 26th, at Kingston House, Camberwell, Samuel Hague M.D., LL.B.Lond.

Wright.—On Sept. 29th suddenly, at his residence, 5, Queen Street, Scarborough, Henry Wright, M.R.C.S., L.S.A., aged 76.

THE ADVANCE OF SURGERY DURING THIRTY YEARS. (*a*)

By A. W. MAYO ROBSON, F.R.C.S.ENG., L.R.C.P.LOND.,

Emeritus Professor of Surgery in Yorkshire College.

As a surgeon I hope I may be pardoned if I refer to the advances of surgery which have been so remarkable since I entered on my medical career. I often wonder what he would think could one of the great surgeons of the past return and spend a week in our splendid operating theatres. His first surprise would be to see the patient sleeping quietly while the operation was being performed without fuss or worry. What a contrast to the terrible ordeal of the pre-anæsthetic days, when every moment of the operation caused agonising pain to the patient, and the only chance of relief was by a merciful attack of syncope, and when efficiency had necessarily to be sacrificed to expedition. Anæsthesia is one of the greatest boons conferred on humanity, and the nineteenth century would have been a prominent one in the history of medicine if it had nothing else to record. The public does not as yet perhaps fully grasp the fact that it is almost as important to select a good anæsthetist as a good surgeon, for in competent hands anæsthesia itself involves little or no more danger than a railway ride, but with the happy-go-lucky idea that anyone can give an anæsthetic, alarm, if nothing worse, will be certain to arise from time to time, and the surgeon will often be severely handicapped to the detriment of the patient.

What would next attract the attention of our returned master would be the elaborate care and attention to detail in all the stages of the surgeon's work—the boiling of the instruments and everything that can be boiled, the sterilising by high pressure steam of dressings and sponges, and the great care which the surgeon, the assistants, and the nurses employ in purifying their hands and everything that may come in contact with the wounds. Perhaps at first he might be inclined to scoff at so many details, as, indeed, did some of his colleagues and many of his rivals when the author of antiseptic surgery made public his views, but the scoff would be again turned to surprise if he visited the wards a week later and found the patients looking well with normal temperatures and healed wounds; for he would contrast the old days when after such operations, even had they been conceived possible, the patients would in many cases have perished from the numerous wound complications that almost inevitably followed the surgery of that time and those that had survived would have been found suffering from fever and other sequelæ now rarely seen and usually avoidable. It was too literally true, even within my memory, that the mantle of the master descended to the pupil, as I can recall having a stained and gory coat of many colours and of many years' service handed on to me as my prerogative when in 1884 I was elected to the post on the full staff of the Leeds General Infirmary. I hope I did not give offence to my revered predecessor by wearing that coat only on one occasion and in immediately exchanging it for washable garments, but I do know that at the time I was looked on as presumptuous, to put it in the mildest way possible. What would the student of to-day think if he saw silk for ligatures and dressings for the wound taken straight out of the dirty drawers in the operating theatre and handed to the surgeon by the hospital porter, probably with unwashed hands. I think that he would be as much astonished as the old master who returned to see our house surgeons, dressers, and nurses clothed in clean sterilised gowns and wearing sterilised indiarubber gloves in order that their clothes and hands might not contaminate the wound or the instruments. Could he see the elaborate preparation of sponges and ligatures, the careful preparation of the surgeon and the patient, the careful hæmostasis, and the thousand-and-one details of suturing and application of dressings, I think he would feel that verily the times were not for him until he had returned to school. In comparing the present with the past of medicine and surgery and in attempting to forecast the future I have the advantage of being able from my own experience to contrast the work of 1870 with that of 1902. During that interval of thirty-two years so great have been the changes and so marked have been the advances that one cannot but feel a profound sense of gratitude that it has fallen to our lot to have lived and worked through this important period in the world's history and to have contributed in however so small a degree to the reformation which has occurred in our noble profession.

If we compare the report of the Leeds General Infirmary for the last thirty years we shall see not only that the mortality all round has lessened, but that in certain operations, had not a change come, their performance would have had to remain a matter of history, since the mortality was so high as to render them unjustifiable. Just as the number of operations has increased from 469 in 1870 to 4,385 in 1901, so the all-round mortality has diminished from 6·6 per cent. in 1870 to 2·7 per cent. in 1901, although the magnitude of the operations performed has been in many cases infinitely greater.

An analysis of the hospital registers affords interesting and startling facts. For instance, in the 1902 report the following operations are recorded which have no place in the report of 1870: radical cure of hernia, of which no less than 109 cases are given, which means not only a saving of life and suffering but a restoration to efficiency of so many workers who would otherwise have been severely handicapped in the struggle for existence and only rendered possibly safe from the dangers of strangulation by the wearing of a cumbersome instrument. Of osteotomy, or division of the bones, thirty-eight cases are mentioned in the report for 1901.

According to the hospital reports we note that seventy-eight cases of removal of the vermiform appendix are recorded. The attention of the world at large has quite recently been prominently drawn to this subject by the illness of our beloved King. Now, although it would be wrong to say that the disease was

---

(*a*) Abstract of Introductory Address delivered at the Winter session at Yorkshire College, Leeds, on October 1st, 1902.

unknown thirty-two years ago, for it was described by pathologists before that date, yet it is an actual fact that even twenty-five years ago the operation of removing the appendix for appendicitis was practically unknown, though we know that appendicitis with its complications was the cause of death in an immense number of patients who were said to have died from peritonitis. Even in the acute stage of the illness we are now able to save life in a very large percentage of cases by a timely interference, but in the quiescent period, between the attacks, the preventive operation of removing the appendix is almost unattended by risk, a record of several hundred operations of this kind showing no fatality. A reference to the hospital records of recent years shows that in this disease the public are appreciating the fact that prevention is better than cure. Of cholecystotomy and other operations on the gall bladder for the removal of gall-stones and the complications caused by them thirty-eight cases are recorded in the report for 1901. These operations were unknown thirty years ago. We in Leeds have had the proud privilege of helping to advance and to perfect the surgery of the gall-bladder, and in the General Infirmary patients from various parts of the world have sought and obtained relief. These operations have been the means of saving many lives and much suffering, for this form of disease is among the most painful that flesh is heir to. Prostatectomy for the relief of urinary obstruction is an operation that was unknown before 1885. It owes its origin to our late and much lamented colleague McGill, whose name and reputation as a surgical genius add lustre to the Leeds School and in fact to British surgery. He not only originated the operation, but improved and perfected it, and those members of the profession who attended the meeting of the British Medical Association in Leeds in 1889 will remember with what natural pride he showed a number of aged patients in good health on whom the operation had been done. Operations on the intestine, such as the removal of considerable sections, from several inches to even two or three feet, for morbid growth or for gangrene, and various other operations on this portion of the alimentary tract too technical to mention here, are of frequent occurrence now, and bring relief or cure to many patients otherwise doomed to a most painful death. Stomach surgery had no place in the 1870 reports, but in the one issued in 1902 will be found no less than ninety-four operations for various diseases of the stomach. To this advance in surgery the staff of the Leeds General Infirmary have contributed very materially, both in the performance of original operations and in the perfecting of others. As showing the possibilities in this line of work we can point to one now living nearly two years after the removal of nearly the whole of the stomach for malignant disease (at the time of operation he had only at the outside a few weeks to live, yet he now enjoys his meals and to all appearance is in normal health) and also to many men and women restored to a normal state of health, who, but for surgical treatment, must long ago have perished from starvation due to mechanical obstruction of the passage into and out of the stomach. In connection with this line of work no more startling innovation can be noted than the direct treatment of internal bleeding from the stomach, for when general treatment and rest have failed to stop the hæmorrhage we are now able to open the stomach, to search for the bleeding vessel, and to ligature it, instead of standing idly by and watching life slowly slipping away. Nor can anything be more striking than the operative treatment of perforating ulcer of the stomach, where the contents of the stomach, perhaps a full meal, have passed through the opening into the peritoneal cavity, and the patient, who was doomed to death within twenty four or forty-eight hours, is snatched from the verge of the grave by timely surgical interference in which the abdomen is opened and washed out and the perforation is securely stitched up. That the successful removal of part of the liver, of the spleen, and of the kidney is a possibility the reports will show you, yet these operations were not even dreamt of thirty years ago.

But our operative triumphs do not all consist of the removal of diseased parts, as we are able to construct and to build up. For instance, where a bone has been lost, say in the leg or arm, we can engraft and build up a new one, and even where a nerve has been lost or destroyed by disease or injury we are able to transplant a portion of healthy nerve and make good the injury. This operation also had its inception in Leeds, where the first operation of the kind was performed in 1889, a portion of living nerve being transplanted to make up the deficiency in one of the nerves of the forearm, thus restoring sensation and movement to a right hand previously paralysed and which must otherwise have been useless for life. Thanks to the work of Hitzig, Ferrier, Horsley, Jackson, Gowers, and others we are able to map out the site of disease and injury in the brain and spinal cord, and armed with that knowledge surgeons can often attack disease with precision and success. Were it desirable examples could be given of paralysed members being restored to usefulness, of irritating lesions causing convulsions being taken away, of inflammatory effusions and abscesses being localised and removed, and of many other painful and fatal maladies being successfully attacked, practically all these procedures having been first suggested and carried out within the period which I have named. Even a part of a diseased lung has been removed with success, and the evacuation of abscess from within the chest is looked upon as quite an ordinary procedure, yet you would look in vain for these operations in the report for 1870. It would be thought that the heart would be quite beyond the pale of surgery, but so far back as the early "seventies" my distinguished colleagues on the consulting staff, Professor T. Clifford Allbutt and Mr. Wheelhouse, in the Leeds Infirmary successfully attacked an effusion in the sac surrounding the heart and drew off a quantity of fluid that was arresting the cardiac movements. But within the last decade cardiac surgery has made further advances, and you will be astonished to hear that in no less than thirty-eight cases have stab wounds and bullet wounds of the heart been stitched up, with recovery from operation in nineteen cases and complete cure in thirteen cases, yet even when I was a student it was thought that the slightest wound of the heart must inevitably be fatal. The future has probably in store still further advances, for the possibility of opening the heart and dividing certain valvular obstructions which threaten life is even now under consideration. There are many other now well-established, useful, and successful operative measures to be found in the report for 1901, which I could speak of did time allow, that had no mention and which were in fact unknown in 1870. In the same way a reference to the registers shows that some surgical diseases, unfortunately too common in 1870, are now happily rare and in some instances have no place in the report for 1901. I refer to hospital gangrene, pyæmia, erysipelas, septicæmia, and other forms of blood-poisoning, secondary hæmorrhage, and such-like surgical misfortunes. No better examples can be given than that of tetanus or lockjaw, for thirty-two years ago it was not very unusual to see this fatal disease follow even slight operations, yet during the last twenty years I have not seen a single post-operative case, all instances that have come under observation having occurred after neglected wounds received outside the hospital. In the same category may also be mentioned hydrophobia, which has been subdued in England by wise legislation. Perhaps in no class of cases has greater progress to be recorded than in abdominal diseases, which formerly were for the most part treated in the medical wards. For instance, in 1870 and 1871 under the heading "Abdominal Section" no case is reported; in other words, the peritoneal cavity was rarely opened, and then only for ovariotomy and strangulated hernia; whereas in the year 1901 569 patients had abdominal section performed in this hospital for diseases of every organ contained within the abdominal cavity. The statistics of ovariotomy in this hospital twenty-three years ago were so unfavourable that tapping was frequently resorted to in order to defer the operation, and even in 1875 twelve patients were thus treated, only seven having been submitted to the radical operation. Out of these seven five died, yielding a mortality of 71·3 per cent. On the other hand in the year 1901 ovariotomy was performed sixty-four times with sixty recoveries, giving a mortality of 6·2 per cent.; and seeing that this includes malignant, gangrenous, and suppurating cases, as well as those of patients extremely ill in other ways, the mortality is one of which no hospital need feel ashamed.

Just as surgery has taken over the treatment of many medical ailments in the brain, the chest, and the abdomen, so I venture to think that the physician may look forward to the day when the treatment of cancer will return to him and only rarely have to be accomplished by surgical means. Already that chronic form of malignant disease known as "rodent ulcer" is passing from the domains of surgery proper and is being cured by the Röntgen rays, and even the treatment of epithelioma, a more rapid form of malignant disease, is in some cases yielding to similar treatment, as we have been able to show in the Leeds Infirmary. As yet, however, surgery is the sheet anchor of the greater number of cancer cases, and where it has been taken early and treated radically we can point to many patients living active and useful lives many years after the removal of undoubted cancer.

THE POWER OF OBSERVATION IN MEDICINE. (a)

By THOMAS T. WHIPHAM, M.D.Oxon.,
Consulting Physician to St. George's Hospital.

Sir William Gull one day, when in conversation with a colleague, said, "In medicine we make more mistakes by not looking than by not knowing." It sounds like an aphorism of Hippocrates, and I am not sure that even the great Father of Medicine has bequeathed to us one more pregnant with meaning, more universally applicable, or one of more practical utility in medicine and surgery. The aphorism applies not only to medicine; it is equally true in various callings in life, and more especially so, perhaps, in those professions in which an enemy is, if I may use the expression, the *raison d'être* of their existence—in the Navy, in the Army, and—may I add with all due reverence?—in the Church also. The power of being able to see and to appreciate the exact value of the surroundings is of great importance in all ranks of life, and of supreme importance in those professions in which the necessity for organising an attack or preparing for defence forms the chief part of the routine of active service. It may be that the time at a man's disposal for exercising this power is limited to seconds; it may consist in patient and laborious observations extending over a long period of years. Fortunate is the man who is by nature endowed with both. His own reputation, the life of a fellow creature, the existence of a nation, may depend upon his ability to use them.

The faculty of looking is not bestowed upon all of us in equal degree. There are those who neither possess it nor can they acquire it, and these are not for the profession of medicine. They merely "see men as trees walking," or, as Shakespeare so graphically describes the somnambulism of Lady Macbeth:—

> "You see, her eyes are open.
> Ay, but their sense is shut."

Such persons should doubtless seek other and less responsible avocations. "Every man is as God made him and oftentimes a great deal worse." "According to my idea," said Napoleon, "a physician, like a general officer, should be a man possessing great power of discernment and observation which will enable him to discover the strength and position of the enemy." Some men are especially gifted with this power of discernment, but that is no reason why those who are less so should be discouraged. In all probability they are not entirely wanting in some power of observation. Fortunately for themselves they can be taught to cultivate it, just as most boys can be taught to swim; the power is innate and it only requires a little teaching and confidence to call it into action.

"Eyes first, then hands, tongues last and least," is the well-known advice often given to his pupils by the late Sir George Murray Humphry, of Cambridge. Few men have possessed this faculty of observation to a greater degree; no man more thoroughly utilised it in his investigation and treatment of disease. He had more eyes in his head than most people, and he made use of them, every one. Humphry in this phrase wished, as it would seem, to emphasise the importance of a rapid appreciation of surroundings, as compared with a minute and detailed examination by palpation or the voluminous history of a variety of symptoms, the majority of which probably only exist in the imagination of the narrator. What a man sees he can be more or less sure of; what he feels with his hands may be a matter of doubt in dealing with diseases of the human body; what he hears in the history of a case may be altogether erroneous and misleading. Such may, I think, be an amplification of Professor Humphry's phrase. At the same time he was the last man to disparage a carefully-expurgated record of facts, without which diagnosis and treatment would be simply impossible.

The man who lacks this power of looking is the man who cumbers himself with details. We know him in the wards of the hospital and we come across him later—in examination time. He looks into his ink-pot, he looks on his foolscap as he writes out an elaborate history of a trifling ailment, he looks last where he ought to have looked first—at the aspect of his patient. There is little to be done for him, no more than is to be done for the man who is devoid of the sense of humour, who can never see a joke. He must be left to his details.

Now it is by no means impossible for a person outside the ranks of the medical profession to be so far skilled in prognosis, in consequence of having cultivated, quite unconsciously perhaps, the power of looking, as to be able in some cases to predict the event of a disease, the nature and pathology of which are to him unknown quantities. There was, when some of us here to-day were young, a nurse in King's Ward, Mrs. Cran. She was in those days, and I venture to think she would be now, as good a nurse as it is possible to have. As students we would occasionally apply to her for information respecting patients in the wards. Her reply to our questioning would often be something after this style: "I don't know what's the matter with him, but I know he's going to die." From my own recollection it was uncommon for her to be far wrong in her prognosis, whether favourable or otherwise. It was long training and careful observation that enabled her to forecast the future. The possession of "a pair of double million magnifyin' gas microscopes of hextra power," without which Sam Weller, with all his acuteness of vision, was unable "to see through a flight of stairs and a deal door," may not have been vouchsafed to us, but, judging from the instance just mentioned, it is possible for the less appreciative among us to attain by training and perseverance to those three essential requisites of the physician—

> "An eagle's eye, a lady's hand, a lion's heart."

I have chosen as my text a saying of Sir William Gull; let me supplement it by an illustration of the quickness of his power of observation. He had been called into consultation in the case of a lad who had been ill for about a week with fever; otherwise the symptoms were indefinite. He looked at the boy keenly for a few moments, with the body fully exposed; then he placed his hand on the abdomen, and then, having listened attentively to the chest, he retired from the sick room to talk over the case with the doctor in attendance. Now the doctor was not one of those who are characterised by a retiring disposition, and so he at once proceeded, with much confidence and many (to him) irresistible arguments, to set forth his opinion that they had undoubtedly to do with a case of typhoid fever. Sir William Gull listened in silence to all he had to say, and then in his impressive manner replied, "Go back to your patient and look at his belly." He had seen at once that the abdomen was free from distension; he had felt that it was unresisting to pressure, and he in consequence excluded the probability—even almost the possibility—of typhoid fever. The patient shortly afterwards died, the victim of acute tuberculosis. "We make more mistakes by not looking than by not knowing."

(a) Abstract of Introductory Lecture delivered at the Opening of the Winter Session at St. George's Hospital on October 1st, 1902.

In our profession the fact that a man is able to see what he looks at no doubt contributes very materially to his success, for it must be borne in mind that in the management of a patient it is not only his disease that has to be taken into condition but his idiosyncrasies and his peculiarities also. Is he shy and retiring? Is he vain and self confident? Is he hot-tempered and violent? Unless the practitioner is sufficiently observant to have noticed the peculiarity in each case, and possesses the tact and ability to deal with it, he is not likely much longer to retain the individual as one of his patients. By neglecting the aspect of his patient he may deprive himself of the power to render such assistance as his science and his art might be expected to afford. A highly educated physician or surgeon who is wanting in the power of observation may fail, so far as the patient is concerned, where an accurate observer of inferior abilities and attainments will achieve a brilliant success. The necessity for it is perhaps never more fully realised than in the work which devolves upon the medical officer to a life insurance society, and in no branch of medical practice does it stand him in greater stead; in no branch has he better opportunities of testing its value. The duty of a medical officer to an insurance society is not only to detect, as far as may be, the symptoms and signs of incipient disease—a task often of considerable difficulty—but also to form a just and accurate moral estimate of the applicant for a policy. He should be able at his interview with the candidate to judge, for example, how much reliance is to be placed on the answers which a person in pecuniary difficulties and anxious to raise money on a policy thinks fit to return to the questions which are put to him.

Few phrases are, I think, more expressive than the one used by Sir Thomas Watson to describe that remarkable condition of muscular weakness and nervous prostration which so often accompanies different forms of acute and chronic diseases in their later stages. He says that in such circumstances the "patient sinks down in the bed," and in those five words what a picture he paints for those who can see. The whole story is told in a sentence. One can see in a moment most of what has already befallen him, all that at present concerns him, all that his short future in this life is likely to bring him. He is down in the bed because he is unaware that he is so; he is down in the bed because he is powerless to raise himself higher; his sensation is blunted and his feeling benumbed; apathetic and feeble, almost to unconsciousness, he lies utterly regardless of all that surrounds him. But now—

"It is too late: the life of all his blood
Is touch'd corruptibly; and his pure brain,—
Which some suppose the soul's frail dwelling-house,—
Doth, by the idle comments that it makes,
Foretell the ending of mortality." (*King John.*)

The time for the exercise of the faculty of observation is when danger is impending; afterwards it may be too late to retrieve the position. Prompt recognition of the first signs of evil to come is of supreme importance and the failure to appreciate at the moment some apparently insignificant fact may be fraught with disaster to a reputation and involve the possible loss of a life that might be saved.

Let me take an example from everyday life: the occurrence of two or three herpetic vesicles at the angle of the mouth in a patient who comes under observation chiefly on account of high fever and without definite signs pointing to any particular disease. Not much to look at, perhaps, but it affords to the man who has eyes to see it an almost certain indication that typhoid fever may be eliminated from the patient's possible ailments, and that in all probability a few hours will bring forth the physical signs of pneumonia. To take the very common symptom—one of great value as having an important bearing both on prognosis and treatment—that the patient lies with his knees drawn up in the bed. It is a position which at once attracts the attention of him who has eyes to see. Yet it not infrequently escapes the notice of the student and—shall I say it?—of the qualified practitioner also. It seems such a trifling occurrence and so common that it makes no impression on him who is unable to look. This change in the position of the legs should speak volumes to him who is in charge of the patient. It is possibly a fact of great significance; it may indicate two diametrically opposite conditions. It is a sign of hopeful augury on the one hand, and on the other one of grave import. It may mean that the peritoneum is inflamed, the flexion of the knees and the hips serving the purpose of relaxing the abdominal muscles and so relieving the pressure on the tissues that are inflamed. Regarding it as a sign of favourable import, we see in this alteration of posture the evidence of returning vigour, of recovery from the baneful effects of specific fever on the nervous system, as the result of which the patient becomes aware that his extended position is irksome to him and with returning strength makes such changes in it as his wasted and enfeebled muscles permit. Again, note the sharply outlined features of the pallid face, the flush on the cheek, the bright lustre of the eye, the faintly blue tint on the lips, and the probability of tuberculosis is clear at a glance. Observe the dry skin, parchment-like in appearance, the, if possible, still drier lips, which the sufferer endeavours to moisten with a tongue that cleaves to his mouth, the emaciation of the body, the wasting of the limbs, and the presence of diabetes is almost a matter of certainty.

But just a word by way of caution to the junior members of my audience. Let it not for a moment be supposed that from a momentary glance at the aspect of a patient a diagnosis can be made. Aspect, without doubt conveys much valuable information, but diagnosis can only be made by the careful consideration of all facts bearing directly or indirectly upon the case and by the adoption of such methods and appliances, whether ancient or modern, as are likely to assist in the solution of the problem.

Turning more especially to those to whom it is my privilege to welcome to-day, let me impress upon them, at this the commencement of their career, that they must never lose sight of the fact that in all great institutions there are many traditions to be affectionately cherished, to be worthily upheld, and that in this respect St. George's Hospital is by no means an exception. Examples in abundance may be found in the lives and in the deeds of those who have preceded us, who have had so large a share in raising their hospital and its school to the position which it occupies in this city of London.

"Lives of great men all remind us
We can make our lives sublime,
And, departing, leave behind us
Footprints in the sands of Time."

KNOWLEDGE AND WISDOM IN MEDICINE. (a)

By SIR DYCE DUCKWORTH, M.D., LL.D.Ed.,
Physician and Lecturer in Clinical Medicine at St. Bartholomew's Hospital.

I CAN hardly address you here and now without referring to what is surely a vexed question at the present time respecting the proposal to break the bonds which unite you academically with the affiliated colleges of Liverpool and Leeds. Early memories recall to me an abiding rivalry between this and my native city, a rivalry always honourable, though warm with a true Lancashire intensity. I stand here to try and consider this matter with the loyalty of a Lancastrian, tempered, I will venture to hope, by the even-mindedness of an Imperialist long resident in the metropolis. Liverpool has made her decision, and has determined to stand alone and equip herself as an independent University. I feel sure that, whether you regard this step as a wise and provident one, or are of the opinion that it is an unnecessary, and possibly an imprudent, one, you will not be long in following suit, and that you will shortly concentrate within this community of over half a million people all the academic features of this city, and so establish the University of Manchester. Leeds will then have, I imagine, no choice left in the matter, and I shall be surprised if the hard heads and stout hearts of Yorkshire fail to rise to the opportunity of constituting a vigorous University for the largest county in the country. I therefore include myself among those who regard this dissolution as fully within the purview of those who have reached my time of life, and I see no reason for grave concern as respects the outcome of it. In considering the question, the fact must not be forgotten that no new University can by any possibility be made a copy of an older one, for truly a *genius loci* attaches to the character and quality of each; and as Edinburgh is unlike Cambridge, so is Birmingham very unlike Oxford. Certainly, no University of the future will ever resemble that curious but potent academic conglomeration which in its new form is slowly emerging in a corner of the Imperial Institute in London. I think your *genius loci* will carry you through in this city, and a like quality will determine both for Liverpool and Leeds their special needs, and the several methods best fitted to meet them.

(a) Abstract of Introductory Address delivered at the Owens College, Manchester, October 1st, 1902.

After a review of the peculiarities and scope of individual Universities, Sir Dyce Duckworth went on to say that he would have the Universities chiefly concerned in the training of the best candidates for the medical profession, and he would fain have their degrees regarded as honours, not carrying with them State qualifications to practise, but, viewed as indications of distinctly higher attainments conferred on those already holding such diplomas. He urged the necessity of distinguishing between the knowledge which was absolutely necessary for their daily work, and that other variety of knowledge which consists in "knowing about." Dr. Johnson once remarked: "There are two kinds of knowledge, one which you carry in your head, and the other which you know where to find." There were essential and practical parts of their work which must be made their own, worked out and worked in by their hands, eyes, and intelligent attention. These go with you everywhere, as a witty American said—like your fists, added the lecturer. Continuing, he said that no one who considered the matter with an open mind could believe that the medical profession held its legitimate place in public estimation. He believed, however, that estimate to be lower now than was the case half a century ago. While it is certain that the professional knowledge and ability of the great mass of practitioners had increased enormously in recent years, and that the present generation was now better served in all its ills and sufferings than any that has preceded it, it had to be admitted that this appreciation either by the departments of the State or the public was little adequate to its claims. Hospital teachers were sometimes rebuked for their want of loyalty if they fail to encourage their pupils to enter the medical service of the Army. Well, if the country sent its soldier sons to war or to unhealthy parts of the Empire, it was not too much to demand that they should have the service of the best medical skill that could be secured. They would be pleased to recommend the Army Medical Service to their pupils when it was so constituted as to carry no particle of social or professional stigma, and no disability of any kind with it, and when its members were eligible for, and duly received, the recognition bestowed on officers of other departments. The sister service, to which he (the lecturer) once belonged, appeared to him a happier and more attractive one. In this age of monstrous and obtrusive advertisements, continued Sir Dyce Duckworth, we know that almost any figment can, with sufficient money and pertinacity behind it, be readily foisted upon a large section of any community. So with absurd projects of investment, and with a multiplicity of schisms and cults in religion. Consider, for example, that wicked and blasphemous nonsense which is now enlisting the support of many people in America, and of not a few well-placed persons in this country, so improperly called Christian Science or Faith-healing. How much wisdom, think you, is concerned in tenets of that kind? Surely in all these indications of mental feebleness and instability we witness the results of scanty knowledge unbalanced and unchastened by any control derived from wisdom. What are they but conceits and airy delusions which must inevitably go to their doom in failure?

THE MEDICAL CALLING AND CULTURE. (*a*)

By STEPHEN PAGET, M.A.Oxon, F.R.C.S.Eng.,

Surgeon to the Throat and Ear Department at the Hospital.

I may congratulate the new students on their choice of their school, for it would be hard to find anywhere better opportunities for working, or a higher standard of teaching, or more constant help and encouragement. During the last few years an immense amount of time and of money had been spent on the school buildings and they were now almost perfect—well-arranged, well-furnished, and comfortable and healthy to work in; and these material advantages were a very small thing compared to the steady excellence of the teaching and the incessant care that was given to the advancement of every department of the school. Best of all, we work well together; the complex processes of the administration of this great hospital go smoothly, and we are "as a city that is at unity in itself." The new students will find everywhere kindness and goodwill, practical help, and good example; there is no hospital in the world where a man gets more happiness out of his work, or makes better friendships, or learns his business more thoroughly. We might even say that there is no hospital where it is less hard for a man to become what we call "good all round," finding the right way in all things, and sticking to it till the hateful time came when he must say good-bye to this pleasant place. An interesting comparison might be made between hospital life and university life. The hospital buildings may look plain and common-place to strangers, but they have a charm of their own; certainly it would be impossible to find in Cambridge or Oxford any modern bit of building more beautiful than the chapel of the Middlesex Hospital. The hospital garden in summer, when the patients are under the trees and the students are playing tennis, will bear comparison with the empty and useless gardens of the universities all through the long vacation. Our hospital deserves better than any university the name of *alma mater*, for her motherly kindness is not limited to her own sons and daughters, but is extended every year to 4,000 in-patients and 49,000 out-patients. Surely we score here; nobody can call us narrow or selfish or exclusive. Imagine a college at Cambridge or Oxford dispensing culture as we dispense drugs to a daily crowd of unfortunate people who wanted culture; imagine the trivial cases being sent away with culture enough for a week and the serious cases being treated as in-patients till they were sufficiently cultured to be discharged. This sort of university extension is unimaginable; the academic life cannot diffuse itself; we are the one profession whose students are actively and constantly employed in doing good to other people. By this sort of life you learn, as nothing else could teach you, to understand your fellow-creatures. You get a fair insight into social problems; you do not have to go to Toynbee Hall, or any such place, to see how the over-population of London lives, and how drink and preventable diseases, and the sweating system, and immigrant aliens, and dangerous trades, thin their ranks. The proper study of mankind is man; for us that branch of learning is practically a compulsory subject; for undergraduates it is more or less optional. As for the curriculum or studies, nobody can say that it is illiberal, for it is colossal; it would be hard to find a wider or wiser plan of work at Cambridge or

---

(*a*) Abstract of Introductory Address delivered at the Middlesex Hospital.

Oxford, or, having found it, to find many students there able to live up to it. Hospital life just at first might not seem pleasant, but we soon got a hold on our work, and then we begin to enjoy our life here, and each year seems pleasanter than the last. It is, indeed, a dismal affair when the time comes that we must leave the hospital. We have made so many friends and have befriended such a multitude of patients; we have accumulated such an amazing quantity of facts and so many strange experiences. We have had the pleasure of working with the nursing staff of the hospital, which is a privilege hardly to be realised at the universities. Our fellow creatures have been our books; we have studied them in a straightforward non-academical way, without affectation and without embarrassment. Athletics and the medical society and the musical society have helped us to enjoy ourselves and, above all, we have had the delightful sense of membership, or unity, or community, or whatever English word you like to use instead of the phrase *esprit de corps*. Hospital life is not only a curriculum or such things as can be marked in examination; it is the whole man, all through his most impressionable years, under all the good influences of the place. It determines a man's life in practice, not by settling for him the exact line of practice that he should follow, but by making him a good all-round student who will be a good all-round medical man whatever sort of practice he may invest his life in. There were three ways by which a student may increase the value of his life against this day of investment. He ought to master one special subject in addition to his general work; he ought to set himself to obtain, even at the sacrifice of time and money, a resident appointment; and he ought to read hard outside his compulsory books. Read, above all, as Middlesex men, enough to understand something of the work that is now being done here and elsewhere on the pathology of cancer. You are proud of your hospital now; try to think how you will feel when some part of the burden of that disease is at last lifted off the world by the help of our own men here.

HINTS TO MEDICAL STUDENTS (a)

By PERCY FLEMING, M.D.Lond., F.R.C.S.Eng.

Assistant Ophthalmic Surgeon to University College Hospital.

In my own opinion the time has come when the delivery of an introductory address might well be allowed to drop. The occasion, however, possesses one pleasant function, since it affords an opportunity, of which I gladly avail myself, of according to all newcomers a hearty welcome to University College.

If I, speaking as I do in the presence of so many distinguished clinical teachers, may without presumption give my opinion as to the essential factor in clinical teaching I should say that the one thing a student wants to take away from a clinical lecture is a mental picture of the actual patient about whom the lecture has been given, with the methods used to elucidate various facts connected with the illness or injury, and the process of reasoning that has step by step led to the final conclusions. A certain number of so-called clinical lectures appear to me to be really systematic lectures given at the bedside, with nothing more than a passing reference, if even that, to the particular patient. And this leads me to speak of the work done in our new clinical laboratory at the hospital. However valuable and however necessary this work may be, it has this disadvantage—that the investigations are of necessity carried on apart from and without any necessary connection with the patient. For example, the clerk in the laboratory under the direction of our able pathologist makes an exhaustive analysis of the urine, stains films, makes cultivations and blood counts, and writes the reports of the results of his several investigations. Now, if the student's work end there I think a great deal of useful training is lost; the clerk in the pathological department should make it his business to associate any particular laboratory report with the patient whom it may concern. And conversely the clerk in charge of a case should master the details of the pathologist's report on that case, and not merely copy it out. If this be neglected and the work merely be laboratory work it will not confer much benefit on the student, or indeed on anyone. On the other hand, it is impossible to over-estimate the value of the work in the clinical laboratory both to the student and to medicine generally if pains be taken to associate the investigations there with the actual patient in the wards; the dry abstract details of the report will become real, vital, and living if they be associated in one's mind with a particular patient occupying a particular bed, having this or that characteristic appearance, and presenting certain special symptoms. And the same remarks apply, of course, to post-mortem examinations. It is a great gain in one sense that these examinations should be conducted thoroughly and systematically by the pathologist, but much will be lost if the symptoms presented by the patient during life be not elucidated and explained by the post-mortem findings at the time of the examination by one who has had care of the patient during life.

And now I should like to say a few words to those of you who, having completed the curriculum, will be leaving the college in the course of the year. You will find, perhaps to your disappointment, that patients will not be ill according to the type described in the book or lecture. Many cases will require much thought for their elucidation. To be successful you must carry on your practice in a true scientific spirit, the spirit, that is, which is ever seeking the truth, which is always ready fearlessly to speak the truth, though be it remembered this need not be done in a brutal manner. And, gentlemen, you must be prepared to suffer for the truth, and, as Turgot well said, in every-day practice it is so very easy to become indolent in investigation and the slave of routine; it is "indolence, obstinacy, and the spirit of routine" that oppose the progress of truth. If you carry on your work in this way you will have your reward—a reward of course far different and of far greater worth than that gained by letting yourself be the "mouthpiece of the passing beliefs of the popular mind." This may give you popularity, it will give you nothing more substantial.

From time to time letters are written to the medical papers upbraiding the unfortunate authors of these introductory addresses for not warning students and their friends of the hard lot of the general practitioner and the small remuneration he can earn, and ridiculing such an ideal as I have put before you. All I can say with reference to such comments is that if your sole object in entering the medical profession is to make money then you have made a great mistake in joining it. I quite realise that the object you have in mind in becoming students here is to gain the knowledge that will qualify you to earn your living—and any man with ordinary industry who has completed the medical course can always do this—and, as was pointed out last year by Dr. Risien Russell in his introductory lecture, the present time is a very favourable one from this point of view. But if this be the end-all, if there be no love of knowledge for its own sake, then the prospect is, I think, a not very happy one.

It is impossible for me to close this brief address without some reference to the University of London. Most of you know that after much travail and labour a new University of London was born a year or two ago. The period of infancy is always a precarious time, and this particular infant is watched and tended by many experts. Of course, the prime difficulty in all such cases is the feeding. And the food that is needed for this infant University is money; unless money be forthcoming this new University may live, but it will not thrive. Now it has occurred to some that it might assist matters if some of this food be given, as it were, in a predigested form. And so it comes about that instead of actual money this college with its equipment has been offered to the new University of London. But the infant's attendants consider that the entire college may possibly be too much for, and might injuriously affect, the constitution of the new University. And the particular part of the college that in their opinion would so disagree is that part which you and I are most interested in—viz., the faculty of medicine. Negotiations are going on and nothing definite is known about them at present, but from time to time rumours appear in the medical papers about the future of the medical faculty of University College. If the faculty of medicine should cease to exist, what will be the position of our school? If we have lost our connection with the college what shall we possess? In the first place we shall have the hospital, the latest and newest, and therefore the best equipped hospital of the largest city in the world, and, whatever be the future of University College, our medical school will continue to exist, and if it is to flourish we must not be content to live on the reputation of those who have worked here before. They in their day and by their work have made University College Hospital famous, we in our day must see to it that fame does not become tarnished or grow less.

(a) Abstract of Introductory Address delivered at University College Hospital.

SO-CALLED NEURASTHENIA, HYSTERIA, AND ABDOMINAL SECTION:

A CLINICAL STUDY.

By J. STUART NAIRNE, F.R.C.S.,
Senior Surgeon, Glasgow Samaritan Hospital for Women.

Some years ago I had the pleasure of reading a paper at Edinburgh to the Psychological Section of the Brit. Med. Assoc. on a subject which had the very abstruse title of "The Psychology of Muscle." In it I dealt specially with what might properly be called the automatic phenomena of muscular movements in relation to their significance as psychological expressions.

I then stated as probable correct deductions from psychological phenomena many physical conditions that I am now prepared to uphold with practical clinical and physiological observations to support me.

To bring the matter to a point, I do not believe that any psychological phenomena can occur without a corresponding physiological condition, to which the relationship is absolutely direct as effect and cause.

I use the term "so-called" in relation to the words hysteria, neurasthenia, only. These words unfortunately have come, to a large extent, to be associated with the idea of female disorders of a rather discreditable type, and which no woman of a self-respecting character would be subjected to. That is, that to some considerable extent the conditions are quasi-voluntary, and that no woman need actually suffer from them. Of course, there are many scholastic and clinical definitions, none of which perfectly meet the case. In fact, however, any kind of word will meet the case as a definition if only a constant and distinct set of ideas is thereby understood. I discard all definitions that depend on the Greek derivations, because to the ordinary mind they convey absolutely nothing at all. *Sthenos*, strength; *a*, privative; *neuron*, a nerve; *usteros*, of the womb. These terms are emphatically of no use as roots of the meanings of the words hysteria and neurasthenia. It is a popular notion that neurasthenia means that the nerves are too strong for the body, also that they are too weak for the body. Hysteria means a preventable disease, as a fit of hysterics, mostly uncontrollable crying or laughing. If we are seeking, however, for a verbal description of both the conditions concerned here, we would say that the real meaning was that the nervous system was, in whole or in part, so out of co-ordination that it failed to discharge its duties automatically.

The general opinion that in so-called hysterical and neurasthenic affections no organic lesion is to be detected is one that needs much consideration and modification. So that I feel I am on safe and neutral ground when I use these terms of hysteria and neurasthenia to indicate conditions of mind and body and exhibitions of vital phenomena for which no apparently organic condition is openly responsible.

Since I sent in the name of this paper to the secretaries of the section I have noticed with pleasure that in the Psychological Section a very similar subject is set down for discussion on what are likely to be very different lines from this. So that it is evident that something is in the air generally with regard to this abstruse problem, the place of neurasthenia, hysteria, hypochondriasis, *et id hoc omne genus*, in therapeutics, medical as well as surgical.

It is a most gratifying thing to me to see that in the psychological section this subject, in fact this very subject on which I am now engaged, is set down for discussion from the purely psychological side.

The description of the circumstances that have accompanied these cases under my own personal observation compel me to ask whether it is not necessary now to reconsider many of the popular views of these so-called nervous affections, and to ask whether our ordinary methods of diagnosis are quite sufficient for them, and further, to mark down as two special points for consideration:—

1. The non-possibility of neurotic condition without organic lesion, or disturbance of physiological phenomena.
2. The possibility of direct nerve stimulation leading to neurotic conditions without apparent or appreciable organic affection.

Almost without exception abdominal section showed gross or at least palpable lesion of some abdominal organ. In some cases there was kidney or ureter disease.

Some showed sub-peritoneal pelvic disease, tumour or other suppurations, lipomas, tumours of various kinds.

Almost of constant appearance was cystic disease of ovaries, broad ligaments, tubes.

Simple inflammatory conditions of uterus, ovaries or appendages, thickening, soft sodden swelling, twisting of parts, with adhesions to surrounding organs.

Flexions, versions, dislocations of all kinds and of every organ. But the most outstanding pathological condition of all was, what I may term "rigid uterus." It occurred, so far as my observation goes, without exception in all cases where neurosis had been a prominent clinical symptom. It was a great surprise to me in my earlier cases to note this strange condition. And many times I missed it; in fact, did not recognise it at all until a marked pronounced case occurred, when the uterus stood rigidly, almost perpendicularly, up and forced itself on my notice. Once seen it is readily found afterwards. The condition naturally varies in many degrees. It is not necessarily, but frequently, associated with fibroid degeneration of the corpus uteri.

There may be a condition of fixity of the body downwards and backwards either with or without flexion; and this fixity varies in degree also.

So far as I am aware this is an undescribed condition, and can be readily accounted for by some pathological lesion in the cord in the lumbar region controlling the nervous supply to the uterus. If this were so, it is easy to see how cures could readily be accounted for, from the application of electricity internally or externally, from the application of counter irritation, blistering, &c., to the spine, and from the cold douche and baths. Also to the failure of what for want of a better name might be called moral suasion methods. I should like to know what good could be expected from encouragement, or seclusion, or "Weir Mitchell ' or anything of that kind, if it were a *bona fide* fact that there did exist an actual lesion somewhere, and that we had somehow at our hands and to some extent means of diagnosing it.

For, taking for granted that what I say is correct about this spasm of the uterus, what other thing could account for it than the condition of its nerve supply? Hence even can easily be accounted for, the failures that have been recorded in relieving neurotic diseases by abdominal section and removing the appendages. The failures quite as naturally follow as the cures. Should the ultimate disease be absolutely central, and should the cutting off of its nerve supply to the organ not be sufficient to alter it beneficially, then the case must be regarded as a failure. Similarly with all other nerve diseases, *e.g.*, neuralgia, tic. If only one can go far enough back in section of the nerve the disease can be cured. Pains and aches and physical discomforts are not necessarily the only resultants from uterine disease. In a very finely balanced human being pain is a factor that has seriously to be reckoned with. Pain is not always only a physical condition; the poor beetle that we tread upon in corporal sufferance feels a pang as great as when a giant dies. But this is not all. It is the psychological element that comes in and complements all our being. Pain cannot only make us nervous, hysterical, neurasthenic, but can drive us mad.

I would not say that the inflammatory conditions of the appendages that one so frequently finds in an abdominal section are of themselves sufficient to produce these troubles we are considering. I would say that frequently they are of no consequence whatever, that they are merely subsidiary, sometimes only concomitants of the obscure disease that is behind. Similarly I, and I am sure most of you who have removed ovaries, have come to place often very little value on the cystic disease that is almost universally present. No doubt it is a satisfaction, a kind of quasi proof, that an operation has not unjustifiably been done when we can puncture those cysts and show the disease. But in themselves they argue nothing. In many cases they are of no importance whatever.

The argument is not from one condition. It must be from all the conditions together.

There, in such serious cases (for neurasthenia, hysteria are serious enough to threaten both life and reason), must be a consensus of at the very least probabilities. One symptom must be added to another, and when they are all added together, and we find not only some degree of error in position, condition and feeling, but can also diagnose a rigid uterus, then I think we have fairly made good our claim to a probable diagnosis.

In order, however, to put my work as clearly before you as I think I have it before myself, I give you the following table as a summary of results:—

1st.—Abdominal section: No disease found, patient informed, nothing removed, patient apparently cured.

2nd.—Abdominal section: Tuberculous condition, nothing removed, patient apparently cured.

3rd. — Abdominal section: Fibroid condition (uterus, ovaries, or other organ), nothing removed, patient apparently cured.

4th.—Abdominal section: No disease found, nothing removed, patient not informed, patient apparently cured.

5th.—Abdominal section: No disease found, patient and friends informed, patient apparently not benefited.

6th.—Patient under anæsthetic: No section done, patient apparently cured.

7th.—Abdominal section: Appendages removed, patient apparently cured.

8th.—Abdominal section: Uterus removed, patient apparently cured.

9th.—Abdominal section: Appendages removed, patient sent to asylum.

10th.—Abdominal section; Uterus removed, patient sent to asylum.

11th.—Abdominal section: Tuberculous condition, nothing removed, patient not cured.

I hope I shall not be understood as advocating abdominal section in all cases of neurasthenia and hysteria. This would be too dreadful to contemplate. It is the other way about. Some cases of neurasthenia and hysteria demand for their successful treatment abdominal section. And it is because in the course of the major operations I have performed I think I have discovered a valuable sign indicative of the kind of case to which the operation is applicable that I have bracketted "neurasthenia, hysteria and abdominal section" together. It is not necessary to perform a section to diagnose this condition; it only requires greater practice in examination, greater patience in observation, greater discrimination in the valuation of the general signs and symptoms. It does not follow, even if one is convinced the conditions are all there, that an abdominal section will be followed by a cure. And therefore it becomes doubly necessary that everything medical and possible should have been done before resort is had to major operation.

Some short time ago Dr. Rabagliati, of Bradford, published a book on "Ovarian Neuralgia," which will well repay careful perusal. Many of these nervous, hysteric and neurotic women have been treated by us too lightly, indifferently, callously sometimes. To tell the truth, we have good reason to be afraid to deal at all with some of them. When they are not regarded as nuisances, they are often considered pests. And without doubt the nature of their trouble tends to render them somewhat irresponsible for their actions. When we come, however, to realise absolutely and clearly that many of these obscure complaints have a real substantial foundation in some physical condition, although the physical signs may not be sufficiently gross for us to put our fingers on, then our efforts to relieve, receive an impetus that they could not have before; seeing we now know that it is only our knowledge that is at fault, and that it is a reasonable thing to suppose that we may by perseverance in observation and increased skill in management enlarge that knowledge sufficiently to enable us to find out a remedy or remedies. No man can labour diligently in treating diseases unless he has a decided conviction that it is at least possible for him to provide remedies.

(To be concluded in our next.)

ORCHITIS AND PROSTATIC DISEASE.

M. **DESNOS** has published an important article on infections of the epididymis and the testicle in patients suffering from disease of the prostate. Orchitis in such cases can be met with in two forms. One, the simple, produces an inflammatory swelling of the epididymis or the testicle; the neighbouring cellular tissue is the seat of œdema and the tunica vaginalis of moderate effusion. All these symptoms yield promptly to treatment, but frequently the hydrocele persists and some induration of the epididymis. The other form is much more grave, as it consists in numerous small abscesses scattered over the region produced by the infection, and if not treated the patients succumbed from exhaustion. Under the influence of the infection one of the lobes of the prostate becomes swelled and painful, and frequently abscesses are found.

The treatment depends on the origin of the orchitis. If it appears in the course of general urinary infection, the surgeon is disarmed, and can only attempt to sustain the general condition of the patient and to open the collections of matter as they are found. Where the infection reaches the testicle through the vas deferens, a cure may be hoped for; if only one abscess exists a simple incision suffices, but where they are multiplied castration should be performed.

When to Operate in Appendicitis.

The question as to when to operate in cases of appendicitis is still open to discussion in the surgical societies. Some are partisans of immediate operation, while others prefer to retard it until the inflammatory symptoms have subsided. These latter have the advantage of showing a much less mortality. Professor Broca came very nearly settling the question in the discussion on the subject at the annual session of the Surgical Society. After furnishing statistics in favour of the operation *a froid*, he said that the operation could be done during the first ten or twelve hours of the symptoms, and before pus was formed, as advocated by M. Dieulafoy; but the surgeon is rarely ever called at this period, and in any case he might risk to operate where there was no appendicitis (typhoid fever, lead colic, &c.). The reproaches addressed to temporisers might be reduced to one only: that of not being able to foresee how a case of acute appendicitis is going to turn out, and as it was impossible to affirm that it would take a favourable direction, diffused peritonitis might set in which rendered all interference hopeless. An attentive clinical study enabled one to determine what conduct should be taken in face of four principal varieties—diffused peritonitis, circumscribed peritonitis, simple acute appendicitis, and chronic appendicitis.

In case of diffused peritonitis (dry tongue, tympanitis, pain, small and rapid pulse, slight temperature) the operation should be performed without delay, although the chances of the patient are very slight. When the peritonitis is circumscribed, the tongue is loaded but moist, pulse strong and rapid, temperature high, with vomiting. In the right iliac fossa is found a hard swelling painful to pressure. In such cases medical treatment, consisting in opium, applications of ice, absolute rest, &c., should have preference, but on the slightest threat of peritonitis intervention becomes imperative.

When the induration persists several days, and fever and rigor set in, an abscess is certain to exist, but here also the medical treatment may absorb the infiltration. There need be no hurry about opening the abscess, but the patient must be closely watched, and in doubtful cases the operation should be performed without delay.

The indications of operating *à froid* differ as regards the nature of the cases. After two acute attacks every one is agreed that the operation should be done, and the majority of surgeons advise it after the first attack.

As to chronic appendicitis, it is frequently mistaken for other affections, but if really recognised, laparotomy is called for.

Hypertrophy of the Prostate Treated by Bottini's Method.

Volkmann's *Sammlung*, No. 328, contains a paper by A. Freudenberg, on this subject. The paper is an account of his most recent experiences, and they are described as among the happiest achievements of modern surgery. Among his last twenty-five cases treated in this way, he has no fewer than twenty recoveries, four cases materially improved, and only one failure. There were no deaths. By recovery the writer understands freedom from catheterisation, the power of micturition without difficulty, and without burdensome frequency, and the diminution to 50 cm., or a complete absence of residual urine. Such results, according to the writer, can only be obtained by thorough and careful study of Bottini's operation, by manual dexterity, and an acquaintance with bladder diseases. It is a great mistake for a man who is not an expert to attempt to carry out such treatment, and can only bring discredit on the method introduced by Bottini.

At the Hufeland Society, Hr. Martin Greifswald introduced the subject of

Genital Tuberculosis.

Although the subject had been studied before, it was Hegar, in 1886, who first made material progress in it. No part of the tract rejoices in immunity; from the vulva to the ovaries, ligaments and tubes, all are capable of infection. It is not altogether a question of quantity and virulence of germs, but there exists a special disposition to the disease, and it would almost appear that women in whom these parts are functionally active in menstruation, conceptions, and labour had a special predisposition. Then gonorrhœal and syphilitic infections, and, further, the puerperal septic processes, favour the disease by setting up dystrophic conditions and hypoplasia.

Genital tuberculosis is, therefore, generally secondary, but the primary disease is not so rare, according to Orthmann amounting to 18 per cent. The special tracts of infection are fairly clear. Infection from the vagina is caused by coitus, but also by other processes.

The tubes afford an especially favourable soil for infection, and also the ovaries. In a large number of cases the history and the general condition led to a suspicion of the disease. In another series of cases we had only the accumulation of leucocytes, whilst giant cells, central necrosis, and tubercle bacilli were absent. These cases were not conclusive. Thus it happened that in 1,500 gynæcological cases there were only twenty-one in which the disease could be proved to exist. Most of the cases were in the thirties, nine multiparæ; of the remaining twelve must have had children a long time before, probably before the disease began. Only one patient appeared as a young lying-in-woman, and in her the disease was first discovered in childbed.

What was striking was the complete absence of clearness about the symptoms. Eight had more or less pronounced lung symptoms. Others were led to seek advice by accidental causes. Three spoke of wasting; six had only vague abdominal pains, and the genital tract showed nothing noticeable; four had irregular menstruation.

This was remarkable, as in earlier observations these disturbances occupied a place in the foreground. For the purpose of differential diagnosis the symptoms were obscure. In four the peritoneum was diseased, once the ovary, once a tube, eleven times there was tubo-ovarian disease, three times the uterus was the site of the disease, and only once was a tuberculous ulcer found in the vagina. The extraordinary intensity of the caseating process was remarkable. This was strikingly so in the case of a robust-looking girl who thought she was pregnant. Even through the abdominal walls thick, nodular masses could be felt. She was not pregnant. The whole omentum and peritoneum were strewn with nodules the size of a plum, and only a few parts of the peritoneum were intact.

As regards prognosis, of the twenty-one cases four had died, and among them the case of extreme caseation of the peritoneum. One died of sepsis, and one acquired general tuberculosis, and died in six weeks. Four might be looked upon as cured. In the remainder the time was too short for a decision. As regarded treatment, his idea was to remove the infection as radically as possible, but this could only be imperfectly accomplished in presence of metastases.

Hr. Gottschalk then reported a case of tuberculosis of the genitals in a virgo intacta. The disease had appeared in the two preceding generations. She was the sister of a physician, and had first menstruated in her twenty-ninth year. Then irregular hæmorrhages appeared. On examination a papillary growth was found on the portio, in which, after prolonged search, giant cells were discovered. The uterus was otherwise small. At the operation both tubes and ovaries showed caseation, and there was a caseous patch in the uterus. Tubercle bacilli were found in the ovaries and tubes. Attachment of the genitals to the peritoneum had prevented the extension of the disease in parts beyond. The patient had since gained fifteen pounds in weight. He had had two cases of genital tuberculosis in which the patients died later on of tuberculosis of the intestines.

Hr. Gebhard had had a similar case to that of Hr. Gottschalk. He found a cauliflower growth on the portio in which tubercle was found. In reply, Hr. Martin observed that in addition to operation, the other usually employed remedies for phthisis ought to be made use of.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, October 4th, 1902.

Function of the First Rib.

At the Congress for "Innere Medicin" Rothschild brought the function of the first rib forward as an important item in the face of the present treatment for tuberculosis of the lung. It has been affirmed with some show of anatomical reasoning that the cause of the primary deposit in the apex of the lung was due to a fixure of the first rib, or a sort of hereditary ossification, that seriously impeded the proper function of the lung, first producing a stasis in the organ that ended in the deposit of tubercle, and finally led on to destruction.

Surgeons have operated on cases of this kind in the hope of preventing this morbid result. From a conviction that the premises were wrong Rothschild introduced the function of the first rib, and endeavoured to prove that the ossification of the first rib had no effect on the thoracic space, as its principal function was the movement of the manubrium of the sternum. The space or cavity of the chest is determined by the movement of the ribs that alter the sternal angle.

The so-called Schmorl space, he said, was due to an emphysematous expansion of the lung between the pulmonary and costal surfaces, which in a normal state would be occupied with a healthy organ with less pressure.

When a pathological ossification of the manubrium did take place its severance with the body of the sternum was enough, but not the rib from the sternum by resection, as was at present taught and practised, which appears quite irrational when physiologically considered. The next question, he said, was what benefits were to be derived from a separation of the manubrium and the body of the sternum.

Silicates in Phthisis.

Rohden maintains that silicic acid was a natura cement in the tissues that maintained their healthy existence. It prevents the destruction of the mucous membrane and the breaking up of the cell structure, with subsequent decomposition.

Silicic acid is therefore the fundamental binding agent, just as mortar is required to hold the several stones together in an architectural building. The firm hard muscle with its inert elasticity is due principally to the effects of silicic acid, hence its efficacy in therapeutics—increasing the physiology and making the organism more resistant. The acid is usually assimilated and bound up with another constituent of the organism, hence a useful agent in purulent phthisical changes. It ultimately forms a capsule or hardened cicatrix, and prevents the breaking-up of the cells leading on to a fibrous form of phthisis. The fluor and sodia silicates are usually poisonous, although it appears when perfectly pure they are innocuous, *i.e.*, freed from all fluor ingredients which do seem to be injurious. The best way to administer this drug is to combine it with an alkali or the calci-carbonate of iron.

Paraphenyl Diamine Preparation.

Criegern next introduced a discussion by giving his experience and the results of experiments on animals with silicic acid. The poisoning by this drug might be correctly divided into three stages in its course—(1) the cutaneous inflammation, (2) the upper parts of the respiratory tract, and (3) the asthmatical cramping in the bronchial muscles, at the same time expectorating, the Leyden-Charcot crystals, with Curshmann-Ringer's spiral eosinophil cells. During the course of the poisoning nothing particular can be observed in the nerve system or kidneys. Amongst the workers in this substance the skin affections will be the most trustworthy. In a short time some soon become inured to the poison and become immune, but the larger number become more sensitive to the poison, and hence easier affected.

Electric Conductivity of Blood.

Bickel related his experiments with electricity on fluids, particularly blood, and its relation to the power of renal elimination. The conductivity of electricity is relative to the amount the solution contains of a salt acid or base. The freezing point also gives an approximate measure of the substance held in solution. Now by defining the electric conductivity and the freezing point of the serum, both before and after the extirpation of the kidneys, the salts, acids, and bases with their amount can thus easily be determined in the serum, which has radically the same base as the urine; the difference only being a greater concentration of the latter. It is worthy of note that after the removal of the kidney the serum in the blood is *not* concentrated, but a larger quantity of it is present. It must be inferred from these results that it is the volume of the molecular retention that interferes with the metamorphosis in the organism and not the concentration of the fluids.

Cretinism.

Scholz gave a long history of a number of cases of cretinism which he had treated without success. There was no lengthening of the bones, no poisonous phenomena was observed, but there was a decided falling off of the body weight with alarming mental apathy. The gland had effected emaciation by checking metamorphosis and absorbing the entire fat. From this experiment he concluded that the malformation cretinism was not due to athyreosis. Although the gland is undoubtedly useful in myxœdema, it is useless in this case, if not dangerous.

Blum agreed with Scholz in cretinism, but thought it had reducing effect on the myxœdematous also.

Nannyn thought these defects in the treatment applied to sporadic cretinism only.

Kranz could not agree with the previous speakers, as he had always found the gland successful.

The Operating Theatres.

GUY'S HOSPITAL.

Operation for Recent Fracture of the Surgical Neck of the Humerus.—Mr. Arbuthnot Lane operated on a young man, æt. 19, who had been thrown off a horse. He had pitched on to his right shoulder, and the radiograph showed a transverse fracture of the surgical neck of the humerus; the upper end of the lower fragment was displaced forwards and inwards, while the upper extremity was rotated round an axis passing transversely through the head, so that its fractured aspect looked almost directly backwards; it was clear that it would be impossible to bring the fragments into anything approaching apposition by any manipulative process whatever. Mr. Lane exposed the fracture very freely by a long anterior incision and verified the condition as shown in the radiogram; although several days had elapsed since the receipt of the injury the tension afforded by the swollen deltoid acting as a tie in the length of the bone rendered it exceedingly difficult to bring the broken surfaces into accurate apposition and to secure them with wire. This proceeding occupied more than three-quarters of an hour, and proved absolutely, Mr. Lane thought, the absurdity of supposing that any surgeon could, by any means whatever, other than operative, have returned the bone to its normal form. Mr. Lane said he might point out that one advantage of an operation is that it at once relieves the patient of all pain.

The subsequent progress of the case was perfect, the patient leaving the hospital a fortnight after operation.

HOSPITAL FOR SICK CHILDREN.

Ununited Fracture of Humerus.—Mr. Arbuthnot Lane operated on a girl, æt. about 10, who was admitted with an ununited fracture of the humerus, which had been already operated upon by others on two occasions unsuccessfully. The upper extremity below the junction of the upper two-thirds of the lower third of the humerus was flail-like and absolutely useless. The skin and soft parts about the outer margin of the biceps were deeply scarred and punctured; this was the only evidence found of any previous operation. The ends of the fragments were exposed and were found to be rounded and of a fairly dense structure; they were separated by a considerable interval, and no wire was seen in connection with them; the appearance of the skin incision rather suggested suppuration, so that it was possible that any medium used to connect the ends had been removed of necessity. The ends of the fragments were very freely exposed and corresponding sections were made through each at an angle of 45° to the length; the whole was drilled an inch, and a screw, which was well held, retained the planes of bone securely and immovably in an accurate apposition. The wound was then closed and dressing and suitable splint applied. Mr. Lane pointed out that in the case of an ununited fracture of a single bone the use of the screw was essential to command success; he did not mean that it was impossible to obtain union by means of a wire, but, owing to the fact that the areas of bone which can be brought into apposition are relatively small, and the angle formed by the sectional plane with the axis of the shaft necessarily large, it is impossible by any means with which he is acquainted to retain the fragments in accurate apposition and immovable upon one another by means of wire, and unless the surgeon can secure such immobility he cannot be sure of success. He would urge that in undertaking any such operation requiring the use of the screw that the surgeon should make certain before he commences his operation that he has ready at hand such suitable drills and screw-drivers, as are adapted to the calibres of the screws he intends to use, and not to trust to the haphazard collection of rubbish which is to be found in the instrument cases of many hospitals. To do the operation properly it is absolutely necessary to have suitable tools.

ITALIAN HOSPITAL, QUEEN'S SQUARE.

Exploration on the Site of a Nephrorrhaphy Done Four Years Previously. — Mr. Lenthal Cheatle operated on a young woman upon whom he had previously performed nephrorrhaphy on the right kidney, four years previously, at the West London Hospital. The exploration was undertaken at the present because the girl had lately been suffering from symptoms which seemed to point to the organ having again become movable, such as dragging pain, worse on getting about, in the right renal region, together with a feeling of nausea on pressing the kidney; besides, on palpating the kidney, it slipped slightly under the fingers. An incision was made parallel and close to the scar of the old wound along the twelfth rib; this being carried right through the abdominal wall, opened into the kidney, which was practically incorporated with the abdominal parietes. As the symptoms evidently could not have been caused by the kidney having become detached, the abdominal wound was closed, a small piece of the kidney having been first removed, in order to make certain, by microscopical examination, that it was kidney. Mr. Cheatle said it was demonstrated that the operation performed four years ago had been successful; the method then adopted was that advocated by Mr. Jacobson in "The Operations of Surgery," namely, after the withdrawal of the kidney through the wound, a longitudinal incision is made through the capsule of the organ along its convex border. The capsule is then stripped off the kidney up to a point half way along its lateral surface; these flaps are then stitched into the edges of the wound. Although the symptoms in this case had pointed to detachment of the previously stitched up kidney, it was possible, he remarked, that they were the result of a neurotic temperament, this being proved by the negative result of the exploration. Mr. Cheatle pointed out that, viewing the successful result of the first operation, he intended, when practicable, to perform all his nephrorrhaphies by this method.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 8, 1902.

THE INTRODUCTORY ADDRESSES.

THE time-honoured custom of delivering an introductory address by way of a welcome to new students seems to die hard, although there are not wanting signs of a certain fatigue on the part of those upon whom, at intervals, devolves the onerous task of endeavouring to provide an address with some claim to originality. If the addresses which we publish in abstract elsewhere cannot truthfully be described as strikingly original they will, nevertheless, well repay perusal. Taken together they inculcate many important truths, and they give a very vivid picture of the practice of medicine, its requirements, its drawbacks, and its advantages. The student is told, bluntly enough, that if he proposes to practise medicine with the object of making money he has been ill-advised, and there are the usual "offers of compensation" in the form of social esteem and the consciousness of well-doing. It is always good to be reminded that "Most of sterling worth] is what Our own experience teaches," such experience being the outcome of careful observation and trained judgment. It is of the greatest importance to remember that mistakes in medicine are due far oftener to want of care than to want of knowledge, a dictum of which the truth is exemplified in everyday experience. Eyes first, then hands, tongues last and least, is another aphorism, re-edited by the late Sir George Humphry, upon which practitioners, young and old, will do well to ponder. What a man sees, says Dr. Whipham, he can be more or less sure of, what he feels with his hands may be a matter of doubt in dealing with diseases of the human body, and what he hears may be altogether erroneous and misleading. It is no new thing for lecturers to seek to impress upon us the imperative necessity of studying the patient as well as, even in preference to, the disease; but the maxim is one which will bear repetition. After all it is doubtful whether this profusion of "wise saws and modern instances" serve any other purpose than to point a moral or adorn a tale. It would be over-sanguine to suppose that their delivery will modify one jot the future conduct of those who have been privileged to listen thereto. The proper object of these introductory addresses, it seems to us, is rather to interest the student in the career upon which he is about to enter, to place that career before him, not in the light in which it appears to an assistant-physician or junior surgeon who has been waiting eagerly and hungrily during many years for his seniors to withdraw into private life, but rather from the point of view of those who have already achieved success in their calling, who are satisfied with the present and enthusiastic in respect of future developments. Let the lecturers tell their students what has been done and what remains to be done, how they have contributed their quota to the sum of human knowledge and how it lies with their listeners to unravel problems still awaiting solution. The ideal should be high, not pointed at the horizon, for he who aims high will assuredly go higher than he whose vision does not soar above a sign-post. This conception is the one which commended itself to Mr. Mayo Robson, whose stirring address cannot fail to encourage students, new and old, by proving, statistics in hand, that much has been accomplished, and that much more may yet be hoped for. Whatever be the ultimate fate of the introductory address, it is to be hoped that it will not degenerate, as in some instances it exhibits a tendency to do, into mere "tooting" of the particular school. "They are all honourable men," but there is no necessity to blow each little horn on such occasions, even in what Sir Dyce Duckworth calls "this age of monstrous and obtrusive advertisement." If we may be permitted one little word of counsel to future compilers of introductory addresses, it will be to consult a dictionary of quotations in order to be spared the necessity of making use of passages which, by constant reiteration, have long since lost the inestimable quality of freshness and novelty.

FIRE PERILS AT HOSPITALS.

Every year a great number of lives are lost among the general population of this and of other countries as the result of fires. For the most part the history of these fatalities is continuous and fairly even in distribution over the weeks and months of the year. At times, however, it is chequered with the record of some disaster that sends a shock through the civilised world. The burning of the Ring Theatre in Vienna, with its loss of 450 lives, furnished a terrible lesson on the danger of allowing places of amusement to be built without a due regard to fire prevention and to fire exits. Yet theatre construction in our own country is often in a most unsatisfactory condition. The efforts being made at the present moment by the London County Council for reform in that direction are being obstructed tooth and nail by an association of owners and lessees of theatres. It is the old tale of the safety of the public being sacrificed to the greed of vested interests. Other historical disasters were the Opera Comique Fire in Paris in 1887, when 115 lives were lost; the Exeter Theatre in the same year, with 160 deaths; and the Paris Bazaar Fire in 1897, with 124 fatalities. There can be little doubt that, with a proper amount of care, buildings of that kind could be rendered reasonably safe in case of fire. A similar remark applies to churches, where disasters of the kind are more or less regularly recurrent, and which have received a good deal of attention at the hands of those specially interested in fire prevention. That a great deal remains to be done both by way of fire-prevention and of fire-extinction and life-saving is abundantly shown by recent experiences in the metropolis of the United Kingdom. Recently in the heart of London several fires have spread to an extent hardly creditable to the fire-extinguishing resources of the Metropolitan Fire Brigade. Only a few months ago, moreover, eight or nine persons were sacrificed because the brigade was not provided with proper life-saving appliances to reach an ordinary fourth floor about fifty feet above the pavement. That exhibition of incompetence and impotency took place in broad daylight within a stone's throw of a City fire station, while the fire itself was comparatively insignificant and readily extinguished. In the Coroner's inquiry held subsequently it was shown that the safety of workpeople against fire depended on Building and Factory Acts, defective both in nature and administration, and upon a fire brigade furnished with inadequate and antiquated appliances. From these facts it is evident that the public cannot be said to have reached a maximum of security against the preventable risks of fire. It will be well, then, at this juncture, to call attention to another danger in our midst, namely, that of the hospitals. If the danger be great in the case of theatres and churches, which are filled with able-bodied persons, it must be a thousand times greater in the case of hospitals, which are tenanted by a densely crowded and more or less helpless and bedridden population. Yet the construction of hospitals is, for the most part, of such a type as to invite the rapid spread of fire, while their fire-extinguishing apparatus is inadequate or useless. Sooner or later a terrible catastrophe must happen to one of the great hospitals in the United Kingdom. Hundreds of lives will be sacrificed, and after that huge holocaust the Legislature will probably turn a tardy attention to the necessity of regulating the structure of buildings used for hospital purposes. Numerous small fires have been reported from time to time in this country. Only last week an outbreak of the kind took place in the well-known Addenbrooke Hospital at Cambridge, but, although the wards of a portion of the building were entirely destroyed, the inmates, to the number of twenty, were happily rescued. Some day, we venture to predict, on the score of probability, and in the light of accumulated human experience, that the tale of disaster will not end in the destruction of hospital property. More than one serious tragedy of the kind has occurred in the United States. For our own part we hold that it is the duty of every committee of a medical charity to take immediate steps to secure to the utmost possible extent the safety of the inmates within their walls in the directions of fire prevention, of fire extinction, and of life-saving exits and appliances. Further, in the absence of such precautions on a general scale, we hold it to be the plain duty of the Legislature to ensure that all hospitals and asylums for the reception of sick and otherwise helpless members of the community should be provided with the best modern means of prevention of loss of life and of property. Without some such forethought there can be little doubt that the community will one day be shocked by the news of a terrible disaster from fire in one of our hospitals, and will receive one more tragic illustration of the homely adage that "prevention is better than cure."

ENGLISH RULE IN IRELAND AND THE MEDICAL PROFESSION.

The loyal and dutiful address presented by the Royal College of Physicians of Ireland to the newly-appointed Representative of his Majesty in Ireland last week was in thorough accord with the reputation and precedents of that body, and was received most graciously by the Earl of Dudley. This address, with his Excellency's reply, will be found in another column, and will be a source of gratification, not alone to the President and Fellows of the College, but to the medical profession generally. In brief, the loyal address presented by loyal subjects of his Majesty to his Majesty's representative was dutifully presented and graciously received. Unfortunately for the welfare of Ireland, the Earl of Dudley, however, comes over here in two different characters. He comes as the Representative of his Majesty, and he comes as the Head of the Executive Government. The address of the College of Physicians was presented to the Representative of the King, and consequently all political references were rightly forbidden, and all suggestions of dissatisfaction were courteously excluded. We fear, however, that were such references permitted, and were the address to the Head of the Executive Government, the dominant note would not be one of assurance that matters relating to the medical profession in Ireland were in such a condition as to furnish a cause for congratulation to his Majesty's Government, but that, on the contrary, many reasons for anxiety on the parts of the heads of the medical profession as to the future of that profession would be adduced. We do not here refer to grievances affecting the Royal College or the heads of the medical profession in the Irish cities, but we refer to the position in which a great part of the medical profession in Ireland has been placed by the direct action of his Majesty's Government. It is not wise to gloss over dangerous conditions in social life once all hope is lost that the danger may gradually die away of itself, any more than it is wise to allow an abscess to persist in the body once it has reached such a size that resolution is impossible. The experience of statesmen and researches of physicians lead us to the same conclusion, that an evil—if it is an evil—is better displayed to the light of day than allowed to increase in size and danger in secret. Accordingly, we believe that any address from the Heads of the medical profession in Ireland to the Head of the Executive Government would not be complete unless it directed attention to the dangers which invest the future of the Irish Poor-law Medical Service. It is an open secret—that is to say, it is a secret which everyone but the Government knows—that at present a deliberate attempt is being made to lay hold of a public department, which is maintained by the money of the State and of the ratepayers, for the purpose of advancing the propaganda of a political organisation. It is known, and openly declared, that posts in this service shall be given to men, not on account of their qualifications or experience, but because they have enrolled themselves as members of the United Irish League, or because they have given proof of a real or assumed animosity to the State in other ways. Advertisements have been issued calling for candidates for dispensary appointments who are members of the League. Appointment as *locum tenens* for an existing medical officer has been refused because the candidate had served as a medical volunteer in South Africa. Daily, the medical officer in a United League district is harassed and annoyed in the discharge of his duties, because he is not one with the masters towhom the Government have entrusted him. It has come to this, and we say it without fear of contradiction, that, in the greater part of Ireland the fact that a candidate for a post in the Poor-Law Service is a loyal subject of the King is sufficient to ensure his defeat. Further, it will in a short time come to this, unless the Government interferes—and again we speak without fear of contradiction—that in a short time no candidate will be elected in these districts unless he is a member of the United Irish League. This is a position which must cause the most keen anxiety in the minds of the heads of the medical profession in Ireland, and which, were the opportunity given, we cannot but think they would lay before the Head of the Executive Government. The question to be asked is simple. Is a public service, paid for by the State and the ratepayers, to be turned into an appendage of a political organisation, and to be used as a means of spreading disloyalty and sedition? What will be the answer of the Government? Will they wait until the service has been ruined and its prime cause—the relief of suffering—forgotten; or will they makeafirm stand and take the Poor-Law Service out of the hands of its present masters. His Majesty's Representative in Ireland, in replying to the deputation of the Royal College, said, "I am well aware that the help which your profession can render to the ends of good government is of great and increasing importance." The United Irish League, on the other hand says, and truly, that it is well aware of the help, which the disposal of posts in the Poor-Law Medical Service among their supporters gives to the furtherance of the aims of the League. Which view of the matter do the advisers of his Majesty's Government take? Is the Irish Poor-Law Service to be officered by an independent body of medical men, who will be of assistance to the Government by their knowledge of "the wise application of the laws of health and of sanitation," or is it to be turned into the perquisite of a political party, and to be used as a means of rewarding disloyalty?

Notes on Current Topics.

The Shop-Seats Act.

THE law of England—meaning by that term the United Kingdom—is, in truth, mysterious and baffling in its evolution. No sooner has a really sound and beneficial Act been passed than it becomes a kind of happy hunting ground for lawyers of all degrees, from judges to attorneys. The particular kind of sport obtainable is to find some verbal point whereby, with much quibbling and display of stern judicial childishness, the public may be straightway deprived of the goodness of the Act. At the same time much work is provided for the lawyers who join with ardour in the chase that to them is auriferous, although to the rest of the world it is ruinous and sterile. An instance of this ingenious reversal of the spirit of an Act was given last week by Mr. Sheil, the London magistrate. In a case before him the County Council prosecuted a publican for not providing seats under the Seats for Shop Assistants Act, 1899. Hitherto that most salutary measure has worked excellently well, but Mr. Sheil has discovered that the Act must be construed as one with the Shop Hours Act of 1892, which applies only to young persons under eighteen. If that be so, the Shop-Seats Act is pithed of its effectiveness. This decision is certainly absolutely opposed to the spirit of the Act, and would hardly proceed from a broad-minded and resolute Bench. Years ago we remember Mr. Sheil's extraordinary attitude with regard to prisoners of obviously unsound mind, whose responsibility he settled forthwith with an equal amount of self-confident disregard of consequences as that which now apparently leads him in this attempt—for his judgment is, happily, by no means either decisive or final—to throw obstacles in the path of a humane law affecting a class that needs protection.

Counter Prescribing and its Sequel.

A case of poisoning by hydrocyanic acid has been recently investigated at Brighton. A verdict practically of death by misadventure was returned by the jury, who found that the hydrocyanic acid which caused the death was "one of the ingredients of a mixture dispensed by Arthur Thomas Jeeves." From the remarks of the Coroner it appears that the mixture was dispensed by Mr. Jeeves upon his own responsibility and not upon the prescription of a medical man. Moreover, he kept no written record of the amount of acid which was used, nor, indeed, was any note whatever made of the transaction. A precaution demanded legally under any circumstances was therefore omitted under other conditions which are of doubtful legality, namely, those of unqualified prescribing, and the result is death. Under these circumstances it is impossible to avoid the conclusion that, technically, Mr. Jeeves could be indicted for manslaughter, although there is not much likelihood that such a charge could be sustained. So long as chemists undertake the serious responsibility of prescribing medicines, when their plain and bounden duty is merely to dispense mixtures under the orders of qualified medical men, so long will the safety of the public be endangered, and the pathway of the prescribing chemist be mined with disastrous pitfalls. The evidence at the inquest was to the effect that the mixture contained bicarbonate of potash and sal volatile in addition to hydrocyanic acid. The medical man who would order so dangerous and unscientific a combination of drugs would be a reproach to his alma mater.

Anti-Tetanus Serum and its Administration.

Experience with anti-tetanus serum has not, so far, given altogether satisfactory results, but there is reason to believe that its failures may be due in part to the method of administration. Drs. Descos and Barthelemy, of Lyons, recently brought before the French Société de Biologie the results of a series of experiments having for object to determine the influence of the mode of administration on the preventive and curative properties of the serum. They point out that, injected twenty-four hours before inoculation of the active virus, the serum affords absolute immunity in doses (in rabbits) of one ten-thousandth of the body weight, and if injected into the veins the immunity is obtained with one-tenth of the normal dose. Even in doses varying from one to ten-millionth of the body weight the survival of the animal is ensured, though the supervention of symptoms of tetanus may not thereby be altogether prevented. Injected immediately, or within twenty-four hours of the inoculation of the active virus, in doses of one ten-thousandth of the body weight, it invariably prevented its evolution, or at any rate markedly attenuated the symptoms, the results being most satisfactory when injected into the veins. The most important fact observed by them is that if the injection of the serum be delayed until after the period of incubation, *i e.*, until the first appearance of muscular spasm, the serum proved unavailing in ordinary doses except in the cases in which intravenous injections were practised. If, however, much larger doses are employed and repeated every twelve hours recovery followed irrespective of the method of injection. Injected at a period when the disease has attained its full development the serum appears to be incapable of arresting the disease, though in two instances recovery followed its injection into the sub-arachnoid space.

Suture of Wounds of the Liver.

Up to the present no trustworthy system of suture applicable to such solid, and at the same time soft, viscera as the liver and spleen has had any vogue. In fact the usual treatment of any wound of such organs involving more than the investing capsules has been by packing and connecting with the surface. Lately, an American surgeon, Mr. Coffey, of Portland, has devised and published a method of suture which, to say the least, promises well and deserves the consideration of investigators. Its essential feature is the use of a canules-traction suture passing through the deep loops of an ordinary deep suture, and attached to a mat of catgut used as a support on the distal side of the organ, similar mats supporting the ends of the main suture. Mr. Coffey claims that as much pressure as is required can be used, since in each case the pressure is applied to the capsule only, and is equalised by the mats of catgut over some extent of surface, just as pressure is eased on the skin by the use of lead plates.

The Drawbacks of Soothing Mixtures.

The use of narcotics to relieve abdominal pain often has for effect to mask symptoms pointing to grave visceral disease. Many persons suffering from incipient typhoid fever or appendicitis apply to the nearest retail chemist for a soothing draught, and have thereby been enabled to postpone obtaining skilled advice until much, possibly irremediable, mischief has been done. The same remark applies, of course, to the routine employment of narcotics by medical men, but it is to be hoped that by this time practitioners in general are cognisant of the undesirability of prescribing sedatives until the source of the disturbance has been ascertained. If we take, for instance, the case of a person suffering from violent abdominal pain due to rupture of a gastric or duodenal abscess, the relief afforded by a hypodermic injection of morphia will divert attention from the grave underlying lesion until surgical aid has become useless. This is even more likely to occur in a comparatively common lesion such as appendicitis, a condition in which immediate diagnosis is all important if the patient is to be protected against the risks inseparable therefrom. Over and over again persons in the initial period of typhoid fever have continued to get about, thanks to repeated doses of sedative astringent medicines, until peritonitis or hæmorrhages revealed the grave nature of the disease. The moral is that the symptomatic treatment of abdominal pain is dangerous and unscientific.

A Curious Charge against a Medical Man.

One of the occasional cases, which emphasise the dangers that a medical man runs, has just made its first appearance in court in the form of an application to remit the trial to the County Court Judge. The plaintiff, a herd in the north of Ireland, claimed damages for the death of his daughter, which it is alleged was caused by the administration to her while under the defendant's care of injurious drugs and medicines. The defendant, who is dispensary medical officer, prescribed for the daughter during the course of an illegitimate pregnancy, and the latter died shortly after the birth of the infant. The accusation apparently is that drugs were administered which procured abortion, but the counsel for the plaintiff did not suggest that they were deliberately administered, but that they were given through negligence. On account of the importance of the case, the medicines in question were sent to the Government analyst, and were found to be absolutely innocent. Accordingly, the application was granted, and the case remitted to the County Court Judge. There is a very widely spread notion among the general public that there are certain drugs which will procure abortion without endangering the life of the patient, and nothing that medical men can say to the contrary will eradicate the notion. The result is that scoundrels of all kinds flourish by duping unfortunate women who desire to escape from the consequences of conception. Such a notion must have been present in the mind of the plaintiff in the present case, or else it is difficult to surmise on what grounds the action was brought. As, however, the case is still *sub judice*, we must not comment further upon it.

Nasal Dysmenorrhœa.

Some months since we called attention to a curious association which was alleged to exist between certain areas of the nasal mucosa and dysmenorrhœa. It was stated that the application of a local anæsthetic, such as cocaine, to the inferior turbinal and to the tubercle of the septum determined marked alleviation of the painful manifestations. Subsequent observations tend to show that this action is in the main due to "suggestion," just as dysmenorrhœa itself is in many instances a neurasthenic manifestation. We know, however, that certain forms of dysmenorrhœa are very amenable to remedies of the analgesic class, and it is quite possible that the absorption of the alkaloid by the nasal mucous membrane may also play a part in bringing about the result. Even if the intranasal treatment of dysmenorrhœa be purely "suggestive," there is no reason why it should not be afforded a trial, especially as the one object which the practitioner has in view is the relief of suffering, no matter by what means. Suggestion is a potent factor in the medicinal treatment of many complaints other than dysmenorrhœa, and is as legitimate a branch of the healing art as any other.

A New Method of Extracting Foreign Bodies in the Ear.

There is no more delicate, and even difficult, task than the extraction, in some cases, of a foreign body which has found its way into the external auditory canal. Irrigation often fails to bring it away, and in certain cases adds to the difficulty by causing the object, a pea for instance, to swell and become more firmly impacted. The employment of instruments is very painful, and requires considerable dexterity, besides supposing an armamentarium specially designed for the purpose, which few practitioners possess. A French physician recommends the use of a piece of soft rubber tube, of a size allowing of its easy introduction, the length of a cigarette. The end is dipped into paraffin and pushed into the canal until it comes into contact with the foreign body, whereupon the operator, applying his mouth to the free end, aspirates forcibly, at the same time throwing back his head. Except in the case of angular bodies of irregular contour the method is usually attended by success, the body coming away with the tube.

The Duplicate Stethoscope.

It is asserted that great assistance may be derived in the diagnosis of pulmonary disease by the employment of a double or duplicate stethoscope, that is to say, an instrument comprising two auditory conduits. These are applied simultaneously to the two sides of the chest, and with a little practice it is said to be quite possible to detect the most minute differences in the sounds heard on either side. Of course some familiarity with the instrument is necessary to obtain the best results, but we are informed that with practice no difficulty is experienced in locating the sounds to their respective source of origin. Perhaps one or other of the enterprising firms of instrument makers will enable us to give this method a trial.

The Mammary Gland Treatment of Uterine Fibroids.

In contrast with the method of treating uterine cancer by the ablation of the breast it is found that the administration of the dry extract of mammary gland provokes contraction of uterine fibromyomata, and in the long run determines retrogression of the growth. One of the first effects is a diminution in the duration and amount of the hæmorrhage to which these growths give rise. As might be expected, the effects are most marked in proportion to the richness of the growth in muscle elements, being less pronounced or absent in growths of a more purely fibrous character.

New Food Plants in Yucatan.

The food problem is the puzzle of existence. As regards the human race, the world is rapidly getting smaller. War, pestilence, and famine still account for much wreckage, but much of human effort is devoted to the preservation and protection of life. Most questions can at least in certain phases be stated in terms of food values. Although we may not aggressively live to eat we most assuredly must eat to live, and so the main element in the daily task is the provision of the daily food. It is encouraging to know from the current number of the *Journal of the Society of Arts* that we have not exhausted our resources as regards nutrients. The gardens and fields of Yucatan, it seems, are filled with succulent vegetables and sweet-smelling herbs unknown to the outer world. In the cultivated fields at the proper season appear Indian corn, beans, and tubers for which we have no name, for the good reason that they have been neither seen nor heard of outside Yucatan. The forests and jungles contain fruits that, excellent even in their wild state, could be made delicious by scientific care and cultivation. There are many wild fruits that offer more promising results than did the bitter wild almond, the progenitor of the peach. All this makes us wish that it were possible to transport some of our hungry submerged with a few Kew gardeners to this veritable Paradise for famished souls. We hope the directorate of the Garden Cities movement will look into this matter.

The Prophylactic Value of Mother's Milk.

Lactation is a physiological function of the highest ethical importance. Suckling would seem among some women to be fast becoming a lost art. It is certainly unfashionable in many quarters. Comparatively few view it as one of the highest duties of motherhood. The making of men, and all that this means, does not come within the philosophy and practice of the would-be up-to-date woman. And thereby they are effectually compassing their own elimination. Few recognise the immense importance of human milk to the developing child. It is more than a mere food. As Professor Welch pointed out, in his luminous Huxley lecture on Wednesday last, a mother's lacteal secretion contained bodies, which, whether of an anti-toxic or allied nature, certainly secured to the suckling a degree of immunity to some forms, at least, of infection. There is reason to believe that this may explain to some extent the terrible slaughter of the innocents from infectious gastro-intestinal catarrh, which every season proves such a scourge to young life. In departing from a compliance with natural law we travel into an unknown land, the darkness of which even the light of science can only feebly penetrate.

Consumption Scares.

Pulmonary tuberculosis is a scourge, and in truth well merits the term of "the great white plague;" but efforts to secure its extermination will not gain much by any methods seeking to provoke a scare. We strongly deprecate attempts in the public Press sometimes made by misguided sanitarians to frighten the people into right doing. The educational value of fear is always slight and generally very ephemeral. The dissemination of reckless statements regarding the manner in which consumption is spread is "hardening the heart of Pharaoh" and staying the feet of progress. In this, as in so many other ills, the old advice is still the best advice: Educate, educate, educate.

The Tuberculous Tube.

The "Tuppenny Tube" has proved a veritable boon to large numbers of London's workers, but, as we have on more than one occasion pointed out, it is not free from certain serious sanitary defects. The lack of adequate, we might almost say any, ventilation the free circulation of dust, the dirty state of many of the cars, platforms and lifts, and the gross overcrowding permitted at certain periods of the day, are all important factors favouring tuberculous infection. Within the last few days we observe the health authorities of the City of London have succeeded in hanging modest-looking cards in inconspicuous positions, politely drawing attention to the objectionable features of spitting. It is time the directorate of the Central London Railway took steps to abate the danger threatening many passengers.

Nurses and Death Certificates.

The modern nurse is often mighty, and, at least with young practitioners, frequently prevails. There must be a limit to the meddlesomeness of mock nurses, and surely the certificate of death might be thought to be sacred from reckless intrusion. But it seems not. According to the daily press, the house surgeon of the Royal Hospital, Richmond, at an inquest recently held, has admitted that "it seemed to have been the practice in that hospital for nurses to make out certificates, and for the doctors to sign them." We hope there is some mistake in the published account, for so unseemly a proceeding calls for the strongest condemnation. We trust the Medical Board of the Richmond Hospital will lose no time in looking into this matter.

The International Congress on Tuberculosis, to be held in Berlin from October 22nd to 26th, will hold its meetings in the Prussian Parliament House. Koch's contention of last year will form the chief subject of discussion.

Sir William Taylor, K.C.B., Director-Genera of the Army Medical Service, will give an address on "The Medical Profession in Relation to the Army," on Wednesday, October 15th, at 8.30 p.m., on the occasion of the annual public night of the Medical Society of University College, London.

The Treatment of Dysmenorrhœa.

It is an old and well-established maxim that a multiplicity of remedies for a particular disease is evidence of the general inefficacity of treatment. This remark assuredly applies to dysmenorrhœa, an ill-understood disorder of probably very diverse origin. It follows that until we have a clearer idea of the etiology and nature of the disorder we must expect remedies, therefore, to make their appearance with the regularity and profusion with which they have hitherto been forthcoming, especially from the United States. Unquestionably there are medicinal agents capable of relieving the distress in certain classes of cases, the difficulty lies in the difficulty of classifying the cases in such a way as to afford distinct indications for this or that treatment. The latest "cure" for dysmenorrhœa is the administration of thyroid extract, and in view of the intimate relationship which exists between the utero-ovarian zone and the thyroid gland the treatment possesses a certain plausibility. Dr. Stinson, of San Francisco, asserts that he has been successful in eighty per cent. of his cases. His plan is to give a grain of the dry extract of the gland three times for a day or two preceding menstruation, doubling the dose during the period.

The Mania for Medical Advertisement.

Of late members of the medical profession seem to have been bitten with a perfect mania for advertisement. The example was not improbably set by the baronets and knights of the profession, aided and abetted by their would-be titled *confrères*. For several years the public newspapers have been the recipients of signed letters from these gentlemen upon such topics as the relationship of oysters to disease, the best way of dealing with enteric fever, the value of certain quack drugs, how to exterminate tuberculosis, and kindred questions that would have been just as usefully discussed by way of unsigned communications. It is hardly to be wondered at if their example has been imitated by general practitioners in various parts of the United Kingdom. Two flagrant, if somewhat amusing, instances of this advertising letter have been brought to our notice during the last week. In one of them a Reading practitioner contributed to a London newspaper his views as to the precise nature of the injury to President Roosevelt's knee. His learned description involved references to periosteum, aspirator, drainage-tubes *in situ*, sequestra, and other highly technical terms. The hardihood of his publication is simply unspeakable when it is reflected that all this unnecessary detail resulted from pure imagination, as he had neither seen the case nor, as he admits, read any authentic medical description of the real state of affairs. The second offender is a gentleman in Manchester who, in reference to the recent lamented death of Monsieur Zola, granted an interview to a correspondent of the *Manchester Courier*, in which journal appeared subsequently a long account of the doctor's personal experiences of asphyxiation.

The Royal Orthopædic Hospital.

A letter explaining their position with regard to the sale of site has been published by the President, the Treasurer, the Chairman, and the Honorary Secretary of the Royal Orthopædic Hospital. As this letter has been published elsewhere, we shall content ourselves with a brief comment on its contents. The main points are (1) that the unsuitability of the site for hospital purposes is insisted upon, and (2) it is admitted that no financial advantage would result from the sale. As to the first we can only point out that the operative results could not be surpassed in any building of any other kind or in any other position. The view that a suitable hospital could be erected on the present site is, we believe, strongly held by one of our most powerful contemporaries. As to the financial aspect of the matter, we have all along maintained that to sell a freehold site of the kind would be simply disastrous. Those who have opposed the proposal to sell have advanced the selling price by £12,000, a fact which in itself entitles their continued opposition to the fullest consideration. In our opinion the migration to another site, and that a leasehold for which £500 rent would be payable, will simply add another to the hopelessly debt-laden and ruined medical charities of London. The appearance of this tardy explanation from the committee does not strengthen their position. It seems strange that the committee which turned out the old board on the question of sale has gone on for several years after an entire reversal of its policy and has waited till the sale has been virtually concluded before giving a public statement of the grounds of their action, although they have been repeatedly challenged to justify their position.

Absent-minded Medical Men.

An analysis of the voting at the recent election of a Direct Representative to the General Medical Council reveals some interesting facts. The Registrar reports that out of 23,437 possible votes 10,936 were recorded, or a percentage of 47·61. Of the voting papers returned no less than 220 arrived at too late a date to be lawfully reckoned in the enumeration. Six hundred and thirty-two were returned through the Dead Letter-Office, a fact which offers a fairly good test of the efficiency of the *Register*. Of the 10,956 voting-papers returned within the proper time 179 were invalid from various reasons. For instance, eleven were sent back in the same blank form in which they were issued; eighty-three were unsigned; fifty-one were not fully signed; seven were signed but no vote was indicated; twenty-four were improperly marked; and three stated that the voters declined to vote. A quite unexpected absence of mind is here officially recorded among members of a serious profession. It is perhaps to some extent excusable among busy and overworked men dealing with correspondence not directly concerned with their professional pursuits. At the same time, it must be admitted that medical men are not altogether free from the absent-mindedness which is an inseparable factor of the human mind.

Medical Inspection of School Children.

Matters concerning education are now attracting much attention. In the clash of political and religious opinion we fear the true aspects of education may be lost sight of. At a time when other countries are making strenuous efforts to secure the best development of "the coming race," it is most desirable that we should not neglect the hygienic and strictly medical necessities of school life. Dr. D. S. Davies, the Medical Officer of the City of Bristol, in his annual report just published has an important section on the question of medical inspection in public elementary schools. He shows that we need to "wake up" in regard to this matter. The advisability of appointing school doctors in Germany, we are told, was suggested by Prof. Virchow in 1889, and in 1900 medical inspection of schools was actually in operation in Wiesbaden, Königsberg, Nürnberg, Darmstadt, Frankfort, Dresden, and Leipzig. In 1899 the Board of Health of New York City had 250 medical inspectors for schools at a salary of 360 dollars, with a chief at a salary of 2,500 dollars, In Chicago, in January, 1900, a daily inspection was begun with fifty-six inspectors receiving fifty dollars a month, to work from 9 a.m. till 12 noon. The City of Boston is divided into fifty districts, with a medical inspector to each. Germany and America, the great progressive countries of the world, are alive to the necessity of making the health of the children a matter of first importance. We occasionally appoint a medical officer often quite unfitted for the work by training or special experience to act under the School Board and make the best arrangements he can with the Medical Officer of Health, but at best our methods are blundering, cumbersome, and to a great extent useless.

Changes on the Staff at St. Bartholomew's Hospital.

Great changes in the surgical staff are shortly to take place at St. Bartholomew's Hospital. We understand that one of the surgeons, Mr. Butlin, has intimated to the Governors his intention to retire next month. Again, in the course of the next nine months two of the present surgeons will have to resign their appointments on account of reaching the age limit, at which retirement from the active staff is rendered compulsory. Thus in this short space of time there will be three promotions upon the present assistant surgical staff, and three new assistant surgeons will be added to the staff of the hospital. Such a course of events is entirely unprecedented in the history of the institution, while it is doubtful whether any such thing has ever happened at any other hospital. St. Bartholomew's, as is well known, possesses a large and influential medical school, but it remains to be seen whether even *it* will be equal to supplying three vacancies for assistant surgeons from among its own alumni. As a rule the staff of St. Bartholomew's are always recruited from Bartholomew's men; occasionally, however, some of the appointments on the medical side have been given to alumni of other schools, as, for example, the late Dr. Matthews Duncan, while neither Sir Lauder Brunton, nor Dr. Gee, both at present physicians on the active staff, were educated at the school. A good deal of speculation is already being indulged in in respect to the possible candidates for the three coveted posts; two names are being freely mentioned in this connection, namely, those of Mr. McAdam Eccles and Mr. Bailey, the latter being the present surgical registrar.

The Electric Enema.

The use of electricity in the treatment of chronic constipation due to atony of the lower bowel has long been recognised, but perhaps never to the full extent it deserves. And, indeed, in the intra-rectal use of the galvanic current there was some inconvenience and danger if proper precautions were not adopted. The most important of these risks was the formation of eschars in the bowel, owing to prolonged current applied at one point. M. Boudet, of Paris, has, however, recently introduced a method of application which entirely does away with this risk, and at the same time accomplishes a wider distribution of the current than was possible by other methods. The apparatus used is simple, and the distinctive feature of it is the rectal electrode, which is hollow, and through which an enema of water is given before the current is turned on. The metal itself is entirely protected by rubber, so that the current of electricity only reaches the bowel after passing through the contained mass of water.

The Therapeutic Uses of Gelatine.

We have on several occasions called attention to the remarkable hæmostatic properties of gelatine when injected into the circulation or administered by the mouth. It exerts a marked effect in promoting the plasticity of the blood in the curious condition known as hæmophilia, and, according to Dr. Lancereaux, of Paris, it is also productive of benefit in albuminuria and diabetes. Unfortunately, the effect only lasts so long as the treatment is maintained, but as the doses of gelatine required are comparatively small, and as it is devoid of any collateral effects of a disagreeable nature there is no obvious reason why its use should not be persevered with in the same way as that of thyroid extract in myxœdema.

Annual Medical Service at St. Paul's.

We are requested to announce that the annual medical service at St. Paul's Cathedral, organised by the Guild of St. Luke, will take place this year on the 22nd inst., at 7.30 p.m., when the Bishop of Kensington will preach the sermon. A choir of over two hundred voices, provided by the London Gregorian Choral Association, will render the music. Members of the profession who may desire to attend can obtain tickets for the space beneath the dome by applying to Dr. S. Russell Wells, 24, Somerset

Street, W. It is hoped that wherever possible academic robes will be worn, as heretofore.

We regret to learn that Dr. James Fullerton Hunter, of Hackney Wick, has died from erysipelas following a trivial injury to the nose incurred in the endeavour to escape from a dog which attacked him when visiting a patient. It seems that he had to perform an autopsy on the body of a person who had died of gangrene on the day following the receipt of the injury, and soon after inflammation set in and ultimately caused death.

It is stated that over a hundred surgical cases are awaiting admission at the Cardiff Infirmary, many of them having been on the list for months. We have heard a good deal of the affairs of this institution of late, mostly of the nature of acrimonious discussion, but it is obvious that something more than idle debate is required to place its affairs on a satisfactory basis.

PERSONAL.

Dr. T. H. Milroy, of Edinburgh University, has been appointed to the chair of Physiology in Queen's College, Belfast.

Dr. S. J. Sharkey will deliver the first Hunterian Lecture before the Hunterian Society this (Wednesday) evening.

Dr. T. Montgomerie Alston and Dr. James Kirkland have been placed on the Commission of the Peace for Lanarkshire.

Mr. Guy Elliston has been appointed General Secretary of the British Medical Association, in succession to Sir Francis Fowke.

Professor Johannes Orth, of Göttingen, has been appointed to succeed the late Professor Virchow in the chair of Pathology at Berlin.

Dr. E. Symes Thompson, Gresham Professor of Medicine, will shortly deliver a course of four lectures in the Gresham College, Basinghall Street, E.C., on the subject of diet.

Dr. J. Spottiswoode Cameron will take the chair at the dinner of the Incorporated Society of Medical Officers of Health which is to take place at the Hotel Russell on Friday next.

Dr. H. Radcliffe Crocker has been appointed to deliver the Lettsomian Lectures before the Medical Society of London, and Sir William H. Bennett will deliver the Annual Oration.

Deputy Surgeon-General W. G. Don has resigned his appointment as one of the medical officers of the London recruiting district, a post which he has filled for the last seventeen years.

Sir William Macewen, F.R.S., Regius Professor of Surgery in the University of Glasgow, will be "the guest of the evening" at a dinner which is to be given in his honour at Glasgow on the 31st inst.

Dr. Guilleaume, of Spa, who was the physician constantly in attendance on her late Majesty Queen Marie-Henriette of Belgium, and to whom she was particularly attached, has been created by the King of Belgium a Chevalier de l'Ordre de Léopold.

Sir William Taylor, K.C.B., Director-General of the Army Medical Service, will deliver an address on "The Medical Profession in Relation to the Army," at the annual public night of the Medical Society of University College, on Wednesday, the 15th inst.

Drs. Chicote, Comenge, and Candido, Medical Officers of Health of Madrid, have received the Order of Alfonso XII. Owing to the excellent arrangements they made, Spain was kept free from bubonic plague and small-pox when these diseases had already gained a footing in Portugal. With our contemporary, *El Siglo Medico*, we tender them our congratulations on the high and deserved honour they have received.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

SCOTLAND.

[FROM OUR OWN CORRESPONDENT.]

Sale of Dundee Royal Asylum.—The directors of this institution have agreed to sell the asylum buildings at West Green to the Dundee District Lunacy Board for the sum of £90,000. At a special meeting held for the purpose of considering the matter, it was explained that the Parish Council in distributing their patients between Dundee and Montrose Asylums had made it impossible to carry on West Green without loss. The Parish Council of Dundee was the only large parish council in Scotland which had not full control of the lunatic patients of the district. When the Lunacy Board takes over the asylum there will be one rate for all private patients, and that not higher than the pauper rate.

Glasgow University.—It will be news to many that the University is owner of two-fifths of an unsaleable (and for the past ten years, unprofitable) island in the Hebrides. It shares its responsibilities as a land owner with the Glasgow Corporation, the Royal Infirmary, and the Technical College. The name of the island is Shuna—it lies to the south of Oban, about midway between Mull and Jura. The trustees brought the matter before the Court at its last meeting, asking for authority to dispose of the island. The only use to which it has ever been put is that of sheep grazing, and while at the time it was bequeathed it was believed to be worth £10,000, the only offer ever received has just reached half that amount.

St Andrews University.—Mr. Andrew Carnegie, Lord Rector of St. Andrews, has given £1,500 for a union for women students attending the University.

Glasgow Southern Medical Society.—The first meeting of the session of the above society was held on the evening of Thursday, the 2nd inst., in the rooms of the Southern Medical Club. The retiring president, Dr. Stewart, occupied the chair. Dr. C. E. Robertson, the representative of the society on the board of the Governors of the Victoria Infirmary, gave an account of the year's work of the governors, the chief item of interest being the alleged abuse of the various hospital dispensaries. Dr. Robertson stated that at a meeting of the governors, two of their number, Dr. Pollock and himself, were appointed to look into the matter. They did so, and from the dispensary books of the Bellahouston Dispensary selected twelve cases, and from the books of the dispensary attached to the Victoria Infirmary they selected nineteen cases for further inquiry. At a later meeting of the governors, however, the chairman seemed to think the proportion of cases of abuse were insufficient to warrant them proceeding farther. It was evidently overlooked that the cases selected were only a few out of many noted for a more thorough investigation. The matter unfortunately was dropped, and for the present, at least, this very clamant abuse will still continue. In the discussion which followed the president, Drs. Pollock, Miller, MacGilvray and Richmond took part. The election of office-bearers for the incoming session was then proceeded with. The following gentlemen were unanimously elected to the various posts:—Dr. Jas. Finlayson, hon. president; Dr. Duncan MacGilvray, president; Drs. Thomas Richmond and J. Fraser Orr, vice-presidents; Dr. Thomas Forrest, treasurer; Dr. Andrew Wauchope, secretary; Dr. Matthew Dunning, edit. secretary; Dr, Ralph Stockman, seal keeper; Dr. Chas. E. Robertson. representative to Victoria Infirmary; Drs. Jas. Hamilton, R. J. Carroll, and James Weir, extra members of council; Drs. John Stewart, R. H. Parry, Wm. Watson, Alexr. Millar, H. L. G. Leask, Court medical. A vote of thanks to the chairman and retiring office-bearers concluded the business.

Complimentary Dinner to Sir Wm. McEwan.—It has been arranged to entertain Sir William McEwan, M.D., F.R.S., Professor of Surgery in Glasgow University, and the recipient of a Coronation honour, at dinner on the evening of Friday, the 31st inst. It will be held in the Windsor Hotel, St. Vincent Street, Glasgow. Mr. H. E. Clark, C.M.G., late surgeon-in-chief with the Scottish National Red Cross Hospital in South Africa, will occupy the chair. Any who may wish to be present will kindly communicate with Dr. Freeland Fergus, Blythswood Square, or Mr. Pringle, F.R.C.S., 172, Bath Street, Hon. Secretaries.

BELFAST.'

[FROM OUR OWN CORRESPONDENT.]

Royal Victoria Hospital.—Election of Surgeon and Assistant Surgeon.—The vacancy caused by the resignation of Mr. T. K. Wheeler has been filled up by the promotion of Mr. T. S. Kirk, F.R.C.S., late assistant surgeon, to be surgeon. For the post of assistant surgeon thus rendered vacant there was a hard fought contest between three men, resulting in the election of Mr. Andrew Fullerton, M.D, F.R.C.S.I., by a large majority. Mr. Fullerton was a brilliant student of Queen's College, Belfast, and the Royal University, and has served as registrar at the Royal Victoria Hospital.

Consumption in Belfast.—Reference was made in this column last week to the articles on this subject promised by Mr. Robert Brown in support of his attack on the Public Health authorities of the city. These articles have now been published, and will tax all the well-known ingenuity of the municipal officers to answer. Mr. Brown begins by showing that while the death-rate from consumption in England and Wales has steadily fallen in the last thirty years from 24 to 13·5 per 10,000, in Ireland it has risen from 19·5 to 22·8. In Belfast, it is true, it has fallen a little in the last twenty years, but it still stands at 33, whereas in Glasgow it is 20 and in Paisley 18. Moreover, this fall in Belfast is probably accounted for by the great extension of the borough boundary, taking in healthy and well-to-do suburbs, where the death-rate is very small. The Medical Officer of Health said that, pending the granting of authority for compulsory notification, we were doing all we could; but I fear that now he is "sorry he spoke." Mr. Brown shows the excellent system of voluntary notification in operation in Manchester and Liverpool, which seems to prove most satisfactory in its working. The cases notified—about one-third of all occurring—are nearly all among the poorest classes, and not only do the Corporation help them in disinfecting, &c., but they send a lady visitor, who gives personal instruction in the proper precautions to be taken for the prevention of infection. In Belfast a consumptive may be three months in his grave before Dr. Whitaker hears of the case. Mr. Brown simply scoffs at Dr. Whitaker's reasons for the prevalence of consumption. We have very few slums, yet we have more consumption than Dublin; we have much less rain and fog than Glasgow or Paisley, yet we have 60 to 70 per cent. more consumption than they. As regards unhealthy trades, there is no proof that spinning and weaving as generally carried on are unhealthy, and in any case the proportion of the whole population that is employed in these trades is steadily decreasing, and is now only 10 per cent. Mr. Brown closes his vigorous attack by saying that he does not consider Dr. Whitaker solely or even mainly to blame for the present state of things, as his suggestions to the Health Committee are generally ignored, or, when accepted, are not carried out, and he instances, very aptly, the Infectious Diseases Hospital, the need of which was urged by Dr. Whitaker, and which was authorised six years ago, but which has not yet been begun. What Mr. Brown does blame Dr. Whitaker for is that he constitutes himself a special pleader for the Health Committee, and, though knowing that they are grossly neglecting their duties to the citizens, he assures the citizens that they are doing all that is possible under the circumstances.

Special Articles.

ROYAL ORTHOPÆDIC HOSPITAL.

We have received a communication signed by Lord Denbigh, the president; Mr. Richard Martin, the treasurer; Mr. Harry Marks, the chairman; and Mr. Ernest Flower, M.P., who is deputy-chairman. We do not quite understand the meaning of this belated manifesto, but presume that its object is to furnish some sort of justification for this most unnecessary sale of the hospital's site. The letter contains some expressions which amaze us. For instance, what is meant by the words "proposed sale" when the fact of sale was emblazoned and advertised in front of the hospital in Oxford Street a few days after the annual meeting? What is meant to be conveyed by the terms "comfort and efficiency," and when, so far as we are aware, no complaints on these headings are made by the patients, those most interested. Then, the querulous complaint of "one-sided statements" amuses us, seeing that the columns of the journals have been open to these gentlemen for more than two years, and the furnishing of their reasons eagerly awaited. We can only surmise that now they have sold the hospital, contrary to all sound and experienced advice, they begin to realise the great difficulties of the task before them, and in their extremity contemplate begging for help. Seeing that their chief argument was that the site was too valuable to retain, that its sale for £40,000 would produce enough to build and equip a modern hospital, and endow it with £15,000 at a cost of only £62 10s. to the hospital, they cannot ask for money for building purposes, and the request for any large sum for any purpose will at once expose the gross mistake they have made. They will be asked why they pressed through a sale which they have failed to show to be compulsory or urgent, and then go begging for assistance? Why, they will be told, did you obstinately decline to retain and develop the hospital's property, keep its very valuable site, rebuild free of cost, and gain a clear £600 a year, although you had been asking the public for £500 a year to enable you to reopen closed beds? Why have you elected to pay £500 a year rent, when you were rent free in your present splendid position? Can you or the public body which has consented to the sale show where the real interests of financial advantage to the hospital comes in through this sale? What will or can be their reply? Certainly no statement in the letter addressed to us will in the least meet these crushing objections, and the governors and public may naturally ask why this property was sold without taking the obvious and only right courses, which we pointed out, *i.e.*, to fully acquaint them of the greatly enhanced value of the property as shown by a recent sale in Oxford Street. Also of the *bona fide* offer of a rental of £800 a year, and of a scheme which was submitted to the Charity Commissioners by which the entire hospital could be rebuilt on its present site *free of cost*, leaving a balance to the good of over £100 a year. Seeing that these very important changes occurred *subsequent* to the annual meeting, most assuredly the governors ought to have been summoned to a special meeting by those desiring to sell, and matters clearly and thoroughly explained before their property was disposed of. This most extraordinary omission—which must have been purposive, as attention had been drawn to the necessity for this course by us and others—taken with the fact that the provisions of her late Majesty's charter have undoubtedly been overridden, would make a very interesting case for the law courts, to which those opposed to sale have been referred when the subject has been broached. On the latter ground, *i.e.*, breach of the charter, strengthened as it now is by the deliberate omission just pointed out, it was stated at the annual meeting that the title of the purchasers must be precarious if anyone cared to contest it, especially as the hospital is bound to suffer by the sale of its property. Much more could be said on this matter, and will be, should occasion arise. In the meantime we sincerely congratulate those who have opposed the sale. They have fought a difficult battle and rendered valuable service to the cause of wise hospital management; they have saved the hospital £12,000, and would, if permitted, have saved it very much more. All the valid arguments have been on their side, and had they possessed the sinews of war this sale would not have been permitted, and the hospitals only and very valuable property would have been retained and developed. On the other hand, we say unhesitatingly, in the public interest and those of the management of hospitals generally, that, in our judgment, this sale is quite unnecessary, very unbusinesslike, and most disadvantageous to the hospital.

PAYING PATIENTS IN FEVER HOSPITALS.

It has always appeared to us to be an extravagant anomaly that the Metropolitan Asylums Board should insist upon furnishing gratuitous accommodation for all classes of patients. It is obvious that among the inmates of their fever hospitals] there must be a not inconsiderable proportion of patients who would gladly contribute towards their maintenance in exchange for greater privacy and sundry minor comforts. By allowing them to do so segregation in hospital would be made less repulsive to such sufferers, and the burden on the rate payers would be proportionally reduced. We are, consequently, very glad to see that a motion has been carried in favour of adapting the accommodation to the requirements of the better class of patients. We cannot imagine that the Local Government Board will withhold its consent to the innovation which, though tardy, will unquestionably prove a boon to many.

Correspondence.

THE SCIENTIFIC ASPECT OF THE BACON-SHAKESPEARE CONTROVERSY.

To the Editor of The Medical Press and Circular.

Sir,—In obedience to editorial decision, I proceed to offer for publication in your pages a few of the remarks which I had included in my complete reply to Mr. George Stronach, regarding my views of Lord Chancellor Bacon's scientific attainments. I will first take the item of the last experiment of his life, as it involves a double claim: of martyrdom to science, and of anticipation of "frozen meat." Bacon—like all scholars of his day—was a reader of Plutarch. If there existed a way of reaching the truth in this connection, which, of course, there never has, I would not hesitate to lay a small wager that on the evening before the fatal experiment the ex-Chancellor had been whiling away time with this favourite author, and had struck the following passage (Holland's version): "One there was who demanded upon a time the reason, why the watermen who saile and row upon the river *Nilus*, provided themselves of that water which they drink, in the night, and not by day. Some said, it was, because they feared the sun, which by enchasing and heating the water, maketh it more subject to corruption and putrifaction: for whatsoever is warmed or made hot, the same is always more ready and disposed to mutation, and doth soon alter, by relaxation of the proper and native quality that it hath: whereas cold, by restraining, seemeth to contain and keep each thing in the own kind or nature: and water especially. *Now for the truth of this, that the coldnesse of water hath vertue to preserve, the snow is a sufficient testimony. which keepeth flesh a long time sweet and without corruption. . . .*" Sad it is to reflect that the famous lawyer and "founder of modern philosophy" owed his death to a mixture of scientific ignorance and puerile curiosity! If, instead of making this childish experiment on the roadside, he had driven home and asked the cook some questions, I venture to state that the latter would have enlightened him concerning a physical fact whose recognition can be traced back to the dawn of physical knowledge, and has probably been familiar to every experienced *chef* since the days when Cain founded the first city.

Your correspondent's first specimen of Bacon's "rare sagacity" is "his speculations on colour." Well might the prophetic soul of Francis Bacon cry out: "Save me from my friends!" The reader who wishes to satisfy his curiosity may turn to the third "*Century*" of the *Sylva Sylvarum*, where he will find (item 291) a "speculation" on the causes of colours of metals in solution, which it is almost painful to me to drag into the light. Commenting on the various colours of such solutions, the writer tells us that "The Cause is, for that by their Strength of Body, they are able to endure the Fire, or Strong Waters, and to be put into an Equall Posture; and again to retain part of their principall Spirit, Which two Things (Equall Posture, and Quick Spirits) are required chiefly, to make *Colours* lightsome." Contrast this distressfully childish prattle with the view of the "*divine*" old Greek of twenty centuries before; and ask whether the author of the *Timæus* was not—relatively, at least—worthy of his hyperbolic epithet. I quote from a Latin version: "Est autem color nihil aliud, quàm fulgor è singulis corporibus defluens, partes habens visui ad sentiendum accommodatas." Following this, let your correspondent, and all other readers who may feel interested. note the metrical views of the grand old exponent of the Epicurean philosophy:—

Nullus enim color est omnino materiaï
Corporibus, neque par rebus, neque denique dispar.

. . . .

Caudaque Pavonis, larga, cum luce repleta 'st,
Consimili mutat ratione obversa colores.
Qui quoniam quodam gignuntur luminis ictu,
Silicet id sine eo fieri non posse putandu 'st.
  Et quoniam plagæ quoddam genus excipit in se
Pupula cùm sentire colorem dicitur album,
Atque aliud porro, nigrum cum, et cetera, sentit,

. . . .

Having retired the famous Lord Chancellor into the dusky background, I will ask the modern physicist who has read the above quotations, What is *Newton's* "theory of colours" but a mathematical adaptation of of those propounded by Plato and Lucretius?

I suppose the "remarkable passage on attraction" is that contained in the eighth *Century* of the *Sylva Sylvarum*, which deals with the fact that "The *Turkish-Bow* giveth a very Forcible *Shoot;*" in which he points out that "short Arrows, which they call *Sprights*, without any other Heads, save *Wood*, sharpened, which were discharged out of *Muskets*, and would pierce thorow the sides of *Ships*, where a *Bullet* would not pierce." And a most characteristic specimen of Baconian "science" is added: "But this dependeth upon one of the greatest *Secrets* in all *Nature*; Which is, that *Similitude* of *Substance* will cause *Attraction*, where the Body is wholy freed from the *Motion* of *Gravity*: . . . And in these *Instances* of *Arrows*; For then the

Motion of *Attraction* by *Similitude* of *Substance,* beginneth to show itself." Whether this be the item referred to or not, all modern *scientific* readers must agree that it *is* a "*remarkable passage.*"

Closely connected with the subject of attraction, is, of course, that of gravitation; and your correspondent gives specimens from Bacon and Shakespeare which show that they had "*discovered*" that bodies—even water—fell towards the centre of the earth! In this connection, I will will give one more quotation from Holland's Plutarch. In the course of a discussion of the opinions of the old Greek philosophers, an interlocutor remarks: "Hold not they that the earth is as round as a ball, . . . affirm not they that there be antipodes dwelling opposite one unto another, . . . and would make us believe, that if bars and masses of iron weighing a thousand talents a piece, were let fall down into the bottom of the earth, when they came once to the middle centre thereof, will stay and rest there, albeit nothing else came against them, nor sustained them up?" The acquisition of such knowledge, common to the Greek philosophers of twenty-five centuries ago, tends to diminish the originality of the inspiration of Newton's *apple.* I will here close my epitome.

I am, Sir, yours truly,
John Knott, M.D.

34, York Street, Dublin, October 2nd, 1902.

SUDDEN DEATHS AND NUX VOMICA.

To the Editor of The Medical Press and Circular.

Sir.—The public at large as well as the medical experts must have noticed the increase in sudden deaths in later years. This phenomenon is not peculiar to any clime or country. It seems to pervade civilised communities. The Queen of the Belgians and the Boer general, Lucas Meyers, stand out in relief as within recent weeks. Every practitioner must have observed cases in his experience. The subject has been somewhat delicate with heart, stomach, or other trouble. had occasionally or habitually taken medicine of a tonic nature without marked apprehension, takes a weakness or a fit and is dead in a few moments, or is found dead in bed. Such is the common history, and the verdict is heart failure. Well, I say it is only the rarest exception that occurs to the rule; that the heart never fails without giving marked premonition unless during a fit or the system is affected by a drug. In nux vomica we have such a drug. This is a medicine which is constantly and universally prescribed. Its action, though not the substance, is cumulative, *i.e.*, a smaller dose after a period of its use will produce a greater or more intense action than a larger at the inception. Its use for a time induces spasms of the heart and muscles, especially at night. It induces a condition which I have known to be diagnosed as angina pectoris. Continued, it induces vomiting some time after meals, and the most disagreeable of all, this drug, which passes as an antidote to alcohol, begets a condition of the senses and system utterly intolerable of alcohol. Let a patient be placed on small doses of strychnia for a month or more, and this drug, which will apparently produce great benefit, at an early period will prepare the way for the smallest dose of the beverage bringing on a most miserable state, lightness in head, spasm of heart, trembling of limbs, cold waves along the back and limbs, sighing and sinking feeling at stomach &c. There is scarcely a pill or mixture advertised that does not contain this drug. Every practitioner prescribes it almost daily because of its bitterness increasing, like all bitters, the gastric juice, and because of its contractile influence over the intestinal muscular coat, without thinking of the spasmodic habit induced and the dangerous polarity and irritability produced in the central nervous centres, as well as in the organic ganglia. I am satisfied that the increase in the sudden deaths is not solely due to nux vomica, but I believe a percentage of them is.

Nux vomica is a dangerous drug; the action intended by the therapeutist can be obtained more securely by other agents, and it is monstrous that this deadly substance can be put up in syrups and preparations and purchased at will by the public.

I am, Sir, yours truly,
John Roche.

Kingstown, October 1st, 1902.

THE BACTERIOLOGICAL TEST IN DIPHTHERIA.

To the Editor of The Medical Press and Circular.

Sir,—I should be glad if any of your correspondents could give me some idea of the dependence to be placed on this test as a means of diagnosis in cases of diphtheria, as it has happened to me from time to time to have them returned in which I have notified diphtheria as tonsilitis, and as these cases are detained at the hospital for a greater or less period of time, I infer there must be some obscurity as to the diagnosis even in official sources. For example, within the last few days I have had a case returned which I notified on the 25th ult. and which, according to the notice-board, he discharged on the 4th, but in the same house and in the same family I have notified three other cases of diphtheria, which occurred almost immediately preceding the case in question, and of which I have heard nothing; and in the first of these four cases I obtained a bacteriological test, but relied upon naked sight in the diagnosis of the remaining three. It therefore strikes me as a curious coincidence that three cases of diphtheria should occur in the same house, but that the fourth, the symptoms being likewise referable to the throat, should be one of simple tonsilitis. I have written to the medical superintendent, pointing out this case, and suggesting as an aid to diagnosis that the medical officer should have record of any case that may occur in a house at the same time; as it occurs to me, seeing the dimensions of the Infectious Hospital, and the manner in which cases are scattered amongst different branches, the multiplicity of the disease in the same house might be lost sight of. I could enumerate two or three other curious notifications, but your valuable space forbids.

I am, Sir, yours truly,
Inquisitor.

London, October 5th, 1902.

Obituary.

MR. EDWARD McMILLAN, OF WEIR.

We regret to announce the death of Mr. E. McMillan, L.R.C.S., which took place on the 26th ult., at Lockerbank, Bridge of Weir, near Glasgow, from cardiac disease, at the age of seventy years. He had retired from active professional work, but for over forty years was a busy practitioner in Glasgow, on the south side of the river Clyde. He was of a genial and happy disposition, and much esteemed by his patients and professional brethren alike. At the meeting of the Southern Medical Society held a few evenings ago, reference was made in very feeling terms by the President to Mr. McMillan's death and it was unanimously agreed to send a letter of condolence to the bereaved family. His son, Dr. William McMillan, has succeeded him in practice.

DR. H. DAGONET, OF PARIS.

The death is announced of Dr. H. Dagonet, of Paris, at the ripe age of eighty years, after a long and painful illness. He was honorary physician to Saint Anne's Asylum, Professor of Medicine in the Strasbourg School of Medicine, and the most distinguished French psychologist. Henri Dagonet was born in 1823 at Chalons-sur-Marne; in 1840 he obtained his M.D. Paris, by a thesis on mental diseases. In 1858 he was elected a corresponding member of the Medico-Psychological Society, of Paris. Numerous honours followed from other French medical societies. He was a voluminous writer, and the majority of his contributions on his own speciality were translated into German, Spanish, and Russian.

MR. WILLIAM BIRD, OF HAMMERSMITH.

On Saturday last there passed away at a ripe age, at his residence, Bute House, Hammersmith, Mr. William Bird, F.R.C.S.Ed., M.R.C.S.Eng., whose declining years were made especially bright with the knowledge of the great esteem in which he was held by his brother practitioners, and the frequent visits paid by them to him. He was one of the founders, a Vice-President, the Chairman for many years, and a Consulting Surgeon of the West London Hospital. He was also a Justice of the Peace and a contributor of various papers to the medical journals. His funeral is arranged for to-morrow (Thursday), and it is expected that a large number of the profession will attend as a last mark of respect.

Literary Notes and Gossip.

Those of our readers who are interested in forensic medicine would do well to read Sir Robert Anderson's article, in the *Nineteenth Century and After* for October, on "Professional Criminals."

⁂

The *Empire Review* for October contains some suggestive notes on Life Insurance without medical examination, which medical men acting as advisers to assurance offices would do well to consider.

⁂

Professor Woods Hutchinson, whose work in comparative pathology is well known on both sides of the Atlantic, contributes an attractive sketch—"A Naturalist's Picnic on the Oregon Coast"—to the current number of the *Contemporary Review.*

⁂

The current number of the *Medical Temperance Review* contains a full account of Sir Victor Horsley's interesting speech at the Annual Medical Breakfast held in connection with the British Medical Temperance Association's gathering at Manchester.

⁂

Dr. A. E. Harris has furnished us with a copy of his quarterly report on the health and sanitary conditions of the metropolitan borough of Islington. It is a rich mine of statistical tables, and contains many interesting data concerning a large and important section of the metropolis.

⁂

"A Manual for Assistants' Examination, Apothecaries' Hall," by Mabel F. Stanley, is a most excellent little work, and cannot fail to prove very useful to those for whom it is written, namely, students working up for the Assistants' Examination of the Society of Apothecaries. The information is very clearly and concisely given, and the matter is so arranged as to be easily grasped by the student.

⁂

Dr. E. Hugh Snell, Medical Officer of Health for Coventry, in an interesting report on the isolation and treatment of diphtheria, shows that sixteen hospitals admit membranous croup unreservedly, and forty-six others admit urgent cases or cases where surgical interference may be necessary. It certainly seems a surprising fact that in these advanced times sixty-two out of sixty-eight of the largest general hospitals in the country should still admit such cases. Dr. Snell's report should be consulted by all medical officers of health.

⁂

The "Fish River Bush, South Africa," by W. T. Black, M.R.C.S. and S.A. (Young J. Pentland), is a reprint of a series of articles on the Fish River Bush of Cape Colony, written between the years 1848 and 1852. One can scarcely realise that at such a comparatively recent period such a wild country could exist on the fringe of civilisation; vast areas of land covered with impenetrable bush, with no roads, except those made by the elephant or the larger kinds of buck. Within these recesses hordes of savages have quite recently lived, and such animals as the elephant, the rhinoceros, and the leopard have been seen almost within the memory of the living. It is an interesting and very readable little book.

⁂

The man of law and the man of medicine have many points in common. There is a legal side of medicine as well as a medical side to law. Of recent years many have sought to serve two masters, and between the pursuit of justice and the following of healing have in only too many instances found happiness in neither, mainly because each demands a life's service. But it is right and proper that the man of blood and the man of tape should exercise mutual regard, and extend to each other a respectful yet brotherly support. We therefore cordially recommend our readers not to miss an opportunity of perusing Mr. Hugh H. L. Bellot's charming new work on "The Inner and Middle Temple," and its rich store of legal, literary, and historic associations.

⁂

Dr. Oscar Jennings has done real public service by setting forth so ably and reasonably "The Cure of the Morphia Habit." Both doctor and patient are too apt to consider that there is no cure for this habit, and there is often no strenuous effort on the part of either to combat it. Dr. Jennings weans the patient from this disastrous habit with the smallest amount of suffering. Slow and sure, and comparatively painless is his method. The patient must absolutely obey his doctor. All the circumstances of his life must be carefully arranged, the general health considered, especially the digestion, and the morphia gradually relinquished; Turkish baths often alleviate the troublesome restlessness; bicarbonate of soda relieves the craving, and heart tonics are generally necessary. Cocaine, codeine, and derivates of morphia, such as heroin, are equally prohibited with morphia itself.

⁂

Something more than literary experience is needed to review such a work as that which bears the ambiguous title of "The Cocktail Book" (Macqueen, London). It is described, by the writer, as "a recipe book compiled for private use," in other words, it is written with the object of enabling a gentleman to provide his friends with any of the standard beverages, mixed in an acceptable manner. Without offering any opinion on the salubrity of indulging in these manifold "mixed drinks"- that belonging by right to another department—we note that Angostura Bitters enter into the composition of a large proportion, if not indeed the majority thereof. We have heard Worcester Sauce described "as an English device for giving the same taste to everything," but, in truth, this would hardly apply to the promiscuous use of Angostura Bitters, since their delectable bitterness is so blended and disguised in the formulæ here set forth, as to possess chameleon-like versatility of flavour. Amphitryons with alcoholic proclivities cannot do better than procure this little formulary, if only to relieve a vicious monotony.

Literature.

BASTIAN'S STUDIES IN HETEROGENESIS. (a)

This is the second instalment of these memoirs, the first part having been reviewed in these columns several months ago. The new work continues and amplifies the observations previously recorded, and ranges over a wide field, including the origin of various protozoa from sources as far apart biologically as bacteria and rotifer eggs. The observations are very fully recorded and illustrated by a series of beautiful, if not over-convincing, micro-photographs.

We feel that little can be added in a general sense to our review of Part I. We have, however, undertaken a few control experiments to test the validity of the author's conclusions as to the origin of monads from the pellicle of hay infusions. In dealing with this Professor Bastian describes and photographs a series of appearances found in hay infusions which have formed a distinct pellicle, whereby groups of bacteria become converted into flagellate monads, fungus spores, or amœbæ. A hay infusion was made and divided into two parts, one of which was kept in a shallow glass dish exposed to the air, and the other preserved in a flask with a cotton stopper. The latter was sterilised by boiling on four successive days, and thereafter remained pellucid in the incubation after several days. In the other half bacteria soon made their appearance, and cultures were made from the pellicle before any monads could be seen. A few days afterwards numerous monads were present, and the bacteria having been separated by plates, the sterile infusion was inoculated from the several different colonies, and although the bacteria multiplied rapidly, forming a thin pellicle, and microscopic examinations were repeatedly undertaken, no monads were discovered, nor have been up to the present, more than two months since the inoculation.

(a) "Studies in Heterogenesis." By H. Charlton Bastian, M.A., M.D. Second Part, with 244 illustrations from photomicrographs. 7s. 6d. London: Williams and Norgate. 1902.

The objection lies ready to hand that the number of controls was not extended enough, and this is quite true, but we only wish to show that Professor Bastian would do a real service if he would repeat his experiments with pure cultures of bacteria, or mixtures of pure cultures, and publish the results. The ubiquity of monads and fungus spores is so aggravating an everyday occurrence to the working bacteriologist that it is not astonishing if Professor Bastian's observations be received with the gravest incredulity.

Of the numerous other theses maintained in the memoir some are bacteriological problems, and should be capable of being repeated under known conditions, as has been attempted above. Others are concerned with the transformation of various protozoa into each other, or the transformation of ova of higher forms into protozoa, and in either case such problems are problems of cell-morphology and must be studied as such. Until Professor Bastian or some other authority shows how the cell organs of the derived forms arise from those of the pre-existing cell, zoologists are justified in regarding the observations detailed in the second part of this memoir with suspicion when they come in conflict with facts which form the very basis of modern biology.

FAGGE'S TEXT-BOOK OF MEDICINE. (a)

The second volume of this magisterial text-book deals with diseases of particular systems, commencing with diseases affecting the respiratory tract. The pathological status of pneumonia does not appear to have undergone any change, its etiology remains as obscure as ever, and the pneumococcus is only accorded a provisional relationship to the disease. The unity of phthisis, on the other hand, is formally proclaimed, thus breaking away from the teaching of which the late Sir Andrew Clark was the last exponent, that there were forms of phthisis other than tuberculous. There is a certain aloofness in the authors' remarks on the climatic treatment of the disease which seems to indicate but a qualified confidence in the method now so prominently before the public; indeed, with the exception of cod-liver oil, no medication or system of treatment is referred to in terms calculated to inspire confidence, or even hope, and the text is little more than a recital of the numerous means employed without anything to guide the neo-practitioner in his choice of remedies. The clinical description of the disease and the bearing of the various etiological factors are admirable, and the quotation in verse which heads the chapter—a novel feature in medical works—is a marvel of accurate observation:—

> "While meagre Phthisis gives a silent blow,
> Her strokes are sure, but her advances slow;
> No loud alarms nor fierce assaults are shown,
> She starves the fortress first, then takes the town."
> —*Garth.*

Under the title "Pneumonoconiosis" is described the chronic pulmonary catarrh, culminating in tuberculosis, due to the inhalation of irritating particles of dust, "miner's lung," "knife-grinders' consumption," and the like. There is an important chapter on mediastinal growths which practitioners would do well to study, comprising as they do a group of affections of exceeding gravity and of difficult diagnosis.

The chapter on Diseases of the Heart is a monograph in itself. After an interesting historical review of the progress of auscultation, as applied to this organ, the authors discuss the significance of tachycardia and bradycardia, distinctive phenomena which, though comparatively common, have only been accorded adequate attention of recent years. The authors carefully avoid devoting much space to the discussion of the significance and causation of certain much-debated murmurs. The treatment is very fully described, and one feels that in this department Dr. Pye-Smith is writing from the fulness of his experience.

Under the head of "Diseases of the Alimentary Tract" it is interesting to note that the term "typhlitis" is used, to the exclusion of appendicitis; the latter, indeed, does not even figure in the index, the author holding "the barbarous name, appendicitis," to be unnecessary and misleading, since, as taught by Addison and Willis, all typhlitis begins in the appendix. Incidentally, the author enters a protest against the name "perityphlitis," on the ground of its ambiguity and the fact that its use implies the erroneous belief that suppuration behind and around the cæcum may arise independently of disease of the appendix. We commend these views to the eminent practitioners who are responsible for its employment in announcing the nature of the King's recent illness to the public. We apprehend, however, that "the barbarous name" has come to stay, all scholarly protest to the contrary notwithstanding. It has now fallen into the public domain, and will probably resist all attempts to stamp it out.

In the chapter on "Diseases of the Blood," the authors are curiously reticent in respect of the prophylactic and curative treatment; in fact, no reference whatever is made to the value of chloride of calcium or gelatine in promoting the plasticity of the blood, although virtually these are the only remedies which possess any influence at all in combating the hæmorrhagic diathesis.

The only fault we have to find with the work is the absence of the personal element. It is well to be made acquainted with the views of authorities on this or that subject, but one yearns for a little guidance, a suggestion here and there, as to the value which the authors accord to the hypothesis or deduction under consideration. Practitioners, moreover, would doubtless be glad of more detailed directions for treatment. A multiplicity of remedies without any hint as to the author's own results with their use is rather confusing than otherwise, though, in fairness, we must admit that the authors err rather on the side of reticence in the domain of therapeutics. The object of medicine is curative rather than diagnostic, and diagnosis is vanity unless it be associated with adequate directions for treatment. This important work deservedly occupies an unique position in English medical literature, a position largely due to the authors' extensive experience and special literary aptitudes.

KEAY ON GALL-STONES. (a)

This little volume is a well-written monograph upon the medical treatment of gall-stones. It contains an excellent summary of knowledge upon this important subject, together with the result of considerable personal experience of the author in the same direction. The style is concise and the reasoning close, as shown by the following passage:—"When Mayo Robson affirms that gouty people are more liable to gall-stones because they do not eat nitrogenous food, there are two reasons against accepting his conclusion: First, it has been by no means proved that gall-stones are a special property of gouty people; secondly, though it might under certain circumstances be expedient for those who suffer from gout to limit their consumption of meat, as a matter of fact we do not find that they do so." The writer is not so happy, however, when he goes on to argue: "If gall-stones are the result of living on non-nitrogenous food, what shall we say of India and other tropical countries, where the inhabitants subsist on a diet that is practically non-nitrogenous, and yet scarcely ever suffer from gall-stones." We should like to know on what authority Dr. Keay advances the last statement, which meantime we receive with a considerable amount of reserve. The author discusses the question of operative interference fairly, while at the same time he speaks firmly about the evil of indiscriminate operation. In one case the formation of gall-stones was not stopped by two operations, in both of which large numbers of gall-stones were removed, and in the latter the gall-bladder itself was taken away. The writer has little or no faith in olive oil as a remedy, but that opinion is certainly not shared by many physicians of experience. On the whole this is a valuable little book on a subject of everyday interest to all who practice medicine.

RAYNER ON THE CARE OF THE TEETH. (a)

If the author of this pamphlet before publication had consulted the members of the dental profession whose names he mentions, it is extremely improbable his pages would have seen the light. These gentlemen would have strongly objected to the not very oblique puff he provides for them, especially as their merits are referred to in company with those of "Oriental Tooth-powders," "Californian Syrup of Figs," and other similar compounds not enumerated in official or recognised pharmacopœias. If the author knows very much about the status and constitution of the dental profession, and the subject of dental prophylaxis, he has not made his knowledge very manifest, nor put it in a form easily to be understood by the popular reader whom he addresses. We venture to affirm that the public will not buy the pamphlet, nor will they read it with attention, even if presented to them gratuitously. The author, with the very best motives, has made a mistake; and this, we feel sure, he will himself, on consideration, fully recognise.

THE ELIMINATION OF DRUNKENNESS. (b)

"The fundamental fact at the bottom of the drink question is the physiological action of alcoholic liquors on the animal organism." Such is Dr. Shadwell's contention, and he is surely right. The evils of intemperance are so widespread that everyone claims a right to tender evidence. But prejudice and ignorance hamper a clear understanding of the position. Probably no body of men has a better right to be heard on this matter than the medical profession. Dr. Shadwell certainly writes from intimate knowledge of his subject. Although not altogether free from bias, and in some measure fettered by theoretical considerations, he has admirably succeeded in presenting an intensely interesting and remarkably suggestive study of drunkenness. He has carefully unravelled the records of the past, and believes that there has been a distinct decline in drunkenness. We think the best medical opinion will not uphold Dr. Shadwell that, "so far from women having recently taken to frequenting the public-house, they have never frequented it less." Certainly those in the best position to know are clear as to the marked increase of alcoholism among women. Dr. Shadwell very ably marshals the forces making for temperance and those for intemperance. We fear, however, that he has allowed himself to be swayed unduly by the attractive theories of Dr. Archdall Reid. The section on the principles of liquor legislation is particularly clear and logical, and the study of "the Scandinavian System" is remarkably able. The chapters dealing with the English public-house and the model ale-house admirably illustrate Dr. Shadwell's command of picturesque and incisive English. The section on habitual inebriates is too brief to be of much value. Dr. Shadwell's work is a serious contribution to a particularly difficult and peculiarly perplexing subject. It is by no means a complete or exhaustive presentation of the case. With many of the author's conclusions we are in most thorough agreement, but with much we feel bound to differ. Dr. Shadwell is outspoken; he does not hesitate either to praise or to blame. In many instances we think he is unfair to those with whom he is not in agreement. But in spite of all limitations and all shortcoming, Dr. Shadwell has succeeded in presenting his subject in a notable work, and we have no hesitation in saying that it should be seriously studied by all classes of the community.

Medical News.

The New Veterinary College for Ireland.

The new Veterinary College, which was opened on Wednesday last by the Lord-Lieutenant, is closely connected with the medical profession. The scheme for its foundation was first formulated in 1894, and prominent among the promoters are to be found the names of the late Dr. Haughton, Professor Cunningham, and Sir Christopher Nixon, while the last-named has also received the honour of being the first President. The President, in welcoming his Excellency at the opening ceremony, gave an interesting account of the foundation of the College, and one which shows how much the veterinary surgeons in Ireland will in future owe to private generosity as well as to State assistance. Although the College was only formally opened last week it has received students for the past three years. In the first year of work there were thirty, in the second year fifty-eight, and this year there promise to be about eighty. Professor Mettam, the Principal, was wisely sent by the Governors to inspect the leading continental veterinary schools before the new building was commenced and, in consequence, the College is equipped in accordance with the necessities for the practice of the most modern veterinary surgery. The importance of the relation of veterinary to human medicine is being more and more recognised every day, and we confidently look forward to discoveries in the newly-created College that will still more strongly emphasise that importance, and will prove of the highest value in furthering a solution of the many difficult problems which still delay the progress of human medicine.

London Hospital Medical College.

The following is the result of the examination held for the entrance scholarships:—Price scholarship in science, value £120, Mr. R C. Roberts; scholarship in anatomy and physiology, value £60, Mr. J. T. Macnab; entrance science scholarship, value £60, Mr. S. J. A. Beale; entrance science scholarship, value £35, Mr. H. Morgan; entrance science scholarship, honorary certificate, Mr. H. R. Davies.

Charing Cross Hospital Medical School.

The following entrance scholarships have been awarded:—The Livingstone scholarship (100 guineas) to Mr. W. S. Fenwick, the Huxley scholarship (55 guineas) to Mr. E. Quirk, and a Universities scholarship (72 guineas) to Mr. R. K. Shepherd. Entrance scholarships have also been awarded to Mr. F. Butler (60 guineas), Mr. T. Hallinan (40 guineas), Mr. F. E. Sprawson (30 guineas), and Universities exhibitions (each 36 guineas) to Mr. J. W. Evans and Mr. R. S. Taylor.

The Medical Sickness and Accident Society.

The usual monthly meeting of the committee of the Medical Sickness, Annuity, and Life Assurance Society was held on 26th ult., at 429, Strand, London, W.C. There were present Dr. de Havilland Hall (in the chair), Dr. J. B. Ball, Dr. Walter Smith, Mr. Wm. Thomas, Mr. Wm. J. Stephens, Dr. F. J. Allan, Dr. M. Greenwood, Mr. Frank Wallace, and Mr. Edwd. Bartlett. The sickness experience of the summer has been unusually high, a large proportion of the claims having arisen from accident. Of these more than half have occurred in connection with wheeling, and some of them have caused serious injury, totally incapacitating the member for a lengthy period. In one case, in which the member has been thrown from a tricycle, there is some reason to fear that permanent injury has resulted. In spite of this the funds of the Society are growing very rapidly, now amounting to over £160,000. The number of members is also growing in a satisfactory manner, as the fresh entrants each year are considerably more numerous than the deaths and lapses. As the Society pays nothing for advertisements, the new members are generally introduced by those who have had personal experience of the advantages obtained from membership in the Society. Prospectuses and all information on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

(a) "Rules to be Observed in the Care of the Teeth." By John Rayner, L.R.C.P., Surgeon, &c., formerly Resident Medical Officer Charlton Dispensary, Manchester; Surgeon Warwick Cottage Hospital; late Visiting Surgeon Exmouth Dispensary. Exmouth: H. S. Eland, The Library.

(b) "Drink, Temperance, and Legislation." By Arthur Shadwell, M.A., M.D., Oxon. London: Longmans, Green and Co. Pp. 304. 1902.

Penalty for Contravention of Lunacy Acts.

Mrs. Roach, proprietress of the Alexandra Nursing Home, Tollington Park, was, on Saturday last, fined £20 and costs for receiving certain alleged lunatics in an unlicensed house. A visit of a Commissioner in Lunacy revealed the fact that the "Home" contained eleven patients, nine of whom showed signs of mental derangement, two being "certifiable." The accommodation was exceedingly inadequate, there was no medical supervision, and a strait-jacket was found on the premises which had been made use of. Under the circumstances the penalty inflicted must be regarded as erring, if anything, on the side of indulgence, for a more flagrant violation of the Lunacy Acts it would be difficult to imagine.

Presentation of an address by the Royal College of Physicians of Ireland to the New Viceroy.

On September 30th the following address was presented to the Lord Lieutenant by a deputation consisting of the President and Fellows of the Royal College of Physicians, who waited on him for that purpose. Her Excellency the Countess of Dudley favoured the deputation by her presence at the presentation.

To His Excellency, William Humble Ward, Earl of Dudley and Viscount Ednam, Lord Lieutenant-General and General Governor of Ireland.

May it Please Your Excellency—

We, the President and Fellows of the Royal College of Physicians of Ireland, desire to approach your Excellency upon your arrival in this country as the representative of his Most Gracious Majesty the King, with a cordial welcome and an expression of our devoted attachment to the Throne. We take this opportunity of once more congratulating our Gracious Sovereign on his Providential recovery from his recent dangerous illness, and we venture to express our respectful and earnest hope that King Edward will be able, at no distant period, to visit in person his Kingdom of Ireland and its capital, when he will, no doubt, receive that hearty welcome which has never been wanting on those auspicious occasions on which his predecessors have visited their Irish subjects. The Royal College of Physicians of Ireland, founded in 1667, received, in 1878 and 1890, additional powers from the late Queen Victoria. The President and Fellows of the College have ever been mindful of the great and important functions entrusted to them, both by her late Majesty and by her Royal predecessors, King Charles II. and King William III. and Queen Mary. The President and Fellows have at all times sought to further the advancement of medical science, and to secure a succession of highly educated physicians for the service of the State. A considerable number of medical officers in the Navy and Army hold the diploma of this College, whilst most of those holding the position of medical officer under the Poor-law system in Ireland are also Licentiates of the College. The President and Fellows from time to time have placed their services at the disposal of the Government, more particularly in devising and giving effect to measures bearing upon the public health, and on the present occasion they desire to assure your Excellency of their readiness, now as in the past, to afford to his Majesty's Government their hearty assistance in all matters relating to medicine and the health and welfare of the people. His Excellency, after thanking the representatives of the Royal College for its address, and promising to convey to the King their congratulations upon his providential recovery from his recent dangerous illness, remarked that the recovery itself was, humanly speaking, a very remarkable tribute to the profession in which they were engaged. The honourable history and achievements of the College which they represented, the work in which that College has been engaged for the last 200 years was second to none in social importance, and its success is a matter of common knowledge. Not only in Ireland, but through the whole of the English-speaking world physicians holding the diplomas of that College occupy positions of the highest importance and responsibility, and he had no doubt that it would maintain and increase the reputation which it has already gained, and continue to send out a succession of highly trained men prepared to combat the different forms of disease, and supplied with all the resources which science in these days provides.

Infection by Flies.

At an inquest held a few days since at Fratton, near Portsmouth, it was elicited that an epidemic of diarrhœa of a virulent type has been raging in the district, which was attributed by the medical officer of health to infection carried to the houses by flies from municipal refuse heaps in the neighbourhood. The Corporation has been asked to provide a destructor to obviate this ever-present nuisance, but has turned a deaf ear on the ground of expense. Surely there must be a means of constraining Corporations to abstain from creating a nuisance which is also very dangerous to health. A little progging of its pachydermatous hide by the Press would, perhaps, assist in attaining the object in view.

Pass Lists.

Society of Apothecaries of London.

At the Primary Examination (Part I.), October 1s and 2nd, the following candidates passed in:—

Biology.—F. M. Cunningham, R. J. W. McKane.

Chemistry.—P. A. Sullivan.

Materia Medica and Pharmacy.—C. E. Adams, C. E. Pring.

Primary Examination (Part II.), September 29th, October 1st and 2nd:—

Anatomy.—H. M. Langdale, W. S. Mitchell, E. Moir.

Physiology.—C. Homer, W. S. Mitchell, S. K. Poole, J. W. Rollings.

The Royal University of Ireland.

The second examination in Medicine, Autumn, 1902. The examiners have recommended that the following candidates be adjudged to have passed the above-mentioned examination:—

Upper Pass:—*James S. Dickey, James Donnelly, *David H. C. Given, *Robert Jameson, Sch., James Magill, Michael Shipsey. Those marked with an asterisk may present themselves for the further examination for honours.

Pass; James W. Allen, Herbert W. Carson, John Devane, John Finnegan, Robert S. Kennedy, William J. Leighton, Andrew Leitch, Robert J. Lytle, William T. McCutcheon, William McKee, Timothy Meagher, Michael J. O'Grady, John J. O'Reilly, Maurice A. Power, Gabriel V. Ryan, Patrick Steen, John P. Waters, Thomas West, Jemima B. White.

The Examiners have also recommended that the following candidates be adjudged to have passed in Anatomy and Physiology:—Henry J. Burke, Arthur G. Cummins, Timothy O'Driscoll, Maurice P Scanlon, William M. Woods.

Conjoint Examinations in Ireland.

The following candidates have passed preliminary examination as undernoted:—

A: Honours (in Order of Merit).—R. de S. B. Herrick, W. H. Bomford, E. B. Palmer.

B.: Pass (alphabetically).—O.H. Bowen, R. J. Brookes, H. C. Carden, J. T. Conway, M. E. Cussen, E. H. Daly, P. G. M. Elvery, R. S. Graham, F. M. Hewson, W. E. M. Hitchins, G. J. M. Martin, E. Montgomery, W. M'Bride, E. T. M'Cabe, J. E. M'Donogh, W. R. O'Farrell, D. J. Stapleton, A. D. Woolf, J. Zlotover.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

MEDICAL TERMS IN THE LAY PRESS.

The representative of the *Fourth Estate* is often befogged by the technicalities presented by medical science. Even the *Daily News* suffers from the same complaint. In referring to Professor Welch's luminous lecture on "Immunity" it informs the listening world that "the subject of the lecture, which was purely technical throughout, was '*Humanity.*'" And in a way, perhaps, the pressman was not far wrong.

Mr. R.—"Musset's sign" is a jerky, rhythmical oscillation of the head met with in the subjects of aortic disease, and is especially well marked in aortic aneurism. It has been observed in a certain number of cases but does not appear to be invariably present, so that its diagnostic value is not very great.

TO MASK CASTOR OIL.

A Russian physician suggests the following formula as a means of overcoming the drawbacks of that otherwise useful purgative, castor oil:—Castor oil, 2 ozs.; menthol, 8 grs.; tincture of iodine, 10 minims. We can quite imagine that the taste of the oil is masked by these additions, which, moreover, have the advantage of acting as intestinal antiseptics.

Mr. F. Laurence will find the matter has been already referred to in our last issue.

THE ETHICS OF ADVERTISING.

The proprietors of "Odol," a fashionable dentifrice, are anxious to point out to the medical profession that extensive advertisement of such an article is not incompatible with real merit, and in no wise detracts therefrom. Their object, we are told, is "simply to educate and to enlighten the public on the urgent necessity of a proper care of the mouth and teeth, founded upon strictly hygienic principles." We do not suppose that medical men are likely to take umbrage at a publicity which is quite in accordance with the spirit of the times; indeed, if the proprietors of "Odol" pushed matters to the extent of sending each member of the profession a bottle of the dentifrice we do not suppose that many would feel it incumbent upon them to return it.

Meetings of the Societies, &c.

Wednesday, October 8th.

Obstetrical Society of London (20, Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. Lewers and others. Short Communication: A Uterus showing Rapidly Growing Epithelioma of the Cervix, Death from Recurrence five months after Removal. Paper:—Mr. J. W. Taylor: Complete Inversion of the Uterus of Seven Months' Duration, Failure with Repositors, Anterior Vaginal Cœliotomy, Anterior Uterotomy and Replacement, Recovery.

Hunterian Society (London Institution, Finsbury Circus, E.C.).—8.30 p.m. Dr. S. Sharkey: The Cardiac Muscle from a Clinical Point of View. (First Hunterian Lecture.)

Dermatological Society of London (11, Chandos Street, Cavendish Square, W.). 5.15 p.m. Demonstration of Cases of Interest.

Thursday, October 9th.

British Gynæcological Society (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Professor J. W. Taylor, Mr. B. Jessett, and Dr. Macnaughton-Jones. Papers:—Mr. Jessett: "Some Complications arising subsequently to Cœliotomy." Short Communication:—Professor Taylor: A Case of Uterus Bicornis with Rudimentary Right Horn.

Friday, October 10th.

Clinical Society of London (20, Hanover Square, W.).—8.30 p.m. Papers:—Dr. L. Guthrie and Dr. F. E. Batten: On Unilateral Atrophy of the Optic Nerve associated with Hemiplegia of the Opposite Side. Dr. A. Francis (Brisbane) (introduced by Dr. G. MacDonald): The Nasal Treatment of Asthma. Mr. A. W. Mayo Robson: Ruptured Crucial Ligaments and their Repair by Operation.

Dr. Purves Stewart will give a Clinical Demonstration on some Neurological Cases at Westminster Hospital on Tuesday next, at 4.30 p.m., in connection with the Post-Graduate course at that Institution.

Appointments.

Culross, J., M.A., M.B., C.M. Glasg., Medical Officer to the Cottage Homes of the Newton Abbot Union, Devon.

Duffett, Henry A., F.R.C.S. Medical Officer to the Greenwich Union Children's Home, New Eltham.

Gardner, A. Josephine, M.B., Ch.B.Edin., Resident Medical Officer in the Bruntsfield Hospital for Women and Children, Edinburgh.

Gough, John Harley, M.D., F.R.C.S Edin., Admiralty Surgeon and Agent for Torquay and Babbacombe.

Hayman, C. A., M.D St.And., F.R.C.S., F.R.C.P.I., L.D.S.Eng., Hon. Assistant Dental Surgeon to the Bristol Royal Infirmary.

Holmes, J., M.D.Edin., Certifying Surgeon under the Factory Act for the Bury District of the County of Lancaster.

Johns, H. D., M.D.Durh., Medical Officer of Health for the Hornsea Urban District Council.

Raw, Nathan, M.D., M.R.C.P Lond., F.R.S.E., D.P.H., Physician to the Sanatorium for Consumption at Heswall, Liverpool.

Renshaw, Knowles, Assistant Physician to the Manchester Hospital for Consumption and Diseases of the Throat and Chest.

Sadler, F. J., M.B., B.Ch.Oxon, Medical Officer to the Barnsley Corporation.

Smith, J. F., M.B., M.S.Edin., Certifying Surgeon under the Factory Act for the Whithorn District of the County of Wigtown.

Taylor, W. K., L.R.C.S., L.A.H.(Irel.), Medical Officer for the Milton Abbot District by the Tavistock (Devon) Board of Guardians.

Vacancies.

Down District Lunatic Asylum.—Junior Assistant Medical Officer, not exceeding 32 years of age and doubly qualified. Salary £100, with furnished apartments, board, washing, and attendance. (See Advt.)

Great Northern Central Hospital, Holloway.—Pathologist and Curator of the Museum. Salary 50 guineas per annum. Copies of rules and further particulars may be obtained of L. H. Glenton-Kerr, Secretary.

Jenner Institute of Preventive Medicine.—Assistant Bacteriologist for the Serum Department, Aldenham, Herts. Salary £300 per annum, with furnished rooms. Applications to the Secretary, Jenner Institute, Chelsea Gardens.

Lancaster County Lunatic Asylum.—Assistant Medical Officer. Age not to exceed 30 years. Salary £150 per annum with board, &c. Applications to the Medical Superintendent, Lancaster.

London County Asylum, Horton, near Epsom, Surrey. Junior Assistant Medical Officer. Salary £150 per annum, with board, apartments, and washing. Candidates must be under 30 years of age. Forms of application of R. W. Partridge, Clerk to the Asylums Committee, 6, Waterloo Place, London (see advt.).

Manchester Hospital for Consumption.—Resident Medical Officer for the In-patient Department. Salary £109 per annum, with board, apartments, and washing. Applications to C. W. Hunt, Secretary.

New Ross Union.—Medical Officer. Salary £150 per annum, together with usual Vaccination Fees. The gentleman elected will also act as Medical Officer of Health at a salary of £15 per annum. Applications to P. A. Pope, Clerk of Union. (See Advt.)

St. Mary's Hospital Medical School, Paddington, W.—Demonstrator of Anatomy. Salary £70 per annum. Particulars may be obtained on application to Dr. H. A. Caley, Dean.

Births.

Caldecott.—On Oct. 4th, the wife of Charles Caldecott, M.B., B.S.Lond., M.R.C.S., Medical Superintendent of the Earlswood Asylum, Redhill, of a son.

Collins.—On Oct. 1st, at Ulverston, Lancashire, the wife of Arthur Ward Collins, M.B., D.P.H., of a son.

Fegan.—On Oct. 2nd, at Parkside, Werwyn, Herts., the wife of J. H. C. Fegan, M.R.C.S.Eng., L.R.C.P.Lond., of twin daughters.

Sherren.—On Oct. 1st, at 40, Devonshire Street, Portland Place, London, W., the wife of James Sherren, F.R.C.S.Eng., of a son.

Marriages.

Banting—Villiers-Tuthill.—On Oct. 1st, at St. Paul's Church, Bedford Cecil Banting, M.D., B.S.Lond., F.R.C.S., youngest son of the late William Banting, of St. James's Street, Pall Mall, London, to Ellinor Florence, third daughter of the late Egerton Villiers-Tuthill, of Ballina Srona, co. Limerick.

Bevan—Webb. On Sept. 30th, at St. Mary's Church, Shapwick, Somerest, David John, younger son of the late T. K. Bevan, M.D., of Rickinghall, Suffolk, to Ethel Mille, fifth daughter of the late Henry Wood, Worcester.

Cheatle—Jopp.—On Oct. 2nd, at the Savoy Chapel, London, George Lenthal Cheatle, C.B., F.R.C.S., to Clare Denman, daughter of Colonel Keith Jopp, R.E.

Matthews—Johnston.—On Sept. 30th, at St. Mark's Church, Surbiton, Ernest A. C. Matthews, M.A., M.B., M.C.Cantab., Lieutenant I.M.S., to Anna Stewart, only daughter of Robert Johnston, Esq., of Hillside, Surbiton.

Sanguinetti—Cash.—On Oct 4th, at St. Matthew's Church, Bayswater, Harold Herbert Sanguinetti, M.A., M.B., B.Ch.Oxon., of Minehead, Somerset, to Alice Marian Cash, late of Hove, Sussex.

Sumpter—Muspratt. On Oct. 1st, at All Saints' Church, Upper Sheringham, Eustace Wyatt Sumpter, M.B., B.S., third son of Walter Sumpter, M.D., Cley, Norfolk, to Edith Muspratt Muspratt, third daughter of the late Frederick Muspratt, Esq., J.P., formerly of Liverpool.

Townsend—Woodhams.—On Oct 1st, at St. Marylebone Parish Church, London, Arthur Allen Deykin Townsend, M.B., Ch.B., of Barnwood House, Gloucester, to Julia Florence, widow of Sidney Woodhams, M.R.C.S., L.R.C.P., of Gravesend, and youngest daughter of the late George Edward Sharland, of Gravesend.

Deaths.

Bird.—On Oct. 4th, at his residence, Bute House, Hammersmith, William Bird, F.R.C.S.Ed., M.R.C.S.Eng. (retired).

Forsythe.—On Sept. 30th, at Hazeldene, New Barnet, Anderson Forsythe, B.A., M.D., aged 58.

THE NEW RELIGIO MEDICI. (a)

By SIR FREDERICK TREVES, BART., K.C.V.O., F.R.C.S.,

Serjeant Surgeon to H.M. the King; Consulting Surgeon and Emeritus Professor of Surgery, London Hospital.

SIR FREDERICK TREVES, who was most heartily received, said:—It is right that I should offer to those gentlemen who have just received the prizes the very hearty congratulations of the large audience before whom they have been distributed, and I should like to add to these congratulations my own. I think they are all very much to be congratulated, to this extent, that they have embraced the profession of medicine. Because at no time in the history of the healing art has the profession of medicine ever occupied so excellent a position as it does at this moment. At no period in the history of science has there been a more dramatic interest in its work. There is a certain amount of romance attaching to the merchant adventurers of old, who sailed from Liverpool on all sorts of curious quests, but the romance of that is nothing compared to the romantic voyages of discovery upon which bacteriologists and others concerned in the science of medicine are at this particular moment engaged. And for young men to whom adventure and discovery and the work of the pioneer appeal there can be no business more absorbing than that of the scientific business of medicine. I must be allowed to add, also, that I think those who are becoming members of this medical faculty may be congratulated upon their place of study. Of course, a certain amount of interest, reputation, and picturesqueness belongs to the old seats of learning, but I think the reputation is largely in the past and the beauty and picturesqueness largely those of repose. Here is a teaching body, energetic to a degree almost beyond belief, advancing every branch of science with the most determined and extraordinary vigour, living in every single fibre of their being, and impressing upon every person who steps within that college the impression that he is among a number of men who are absolute pioneers in the particular branch of science in which they are concerned. For a young man to find himself in the midst of an enthusiastic band of this character, such as is found in Liverpool, is, I must confess, an enormous advantage, and certainly a subject for congratulation. As another matter of congratulation I must also say this. Of course, we owe a great deal to our environment, and there is something very stimulating in the atmosphere of Lancashire, although I do not mean necessarily the atmosphere of this individual day. Those who take a map of England, and set to work to read the earnest history of England during the Victorian era, will find that a very large part of that history, and some of the most acute and interesting phases of it, will centre in the county of Lancashire. There is no concealing the fact of the immense vigour with which the history of that county is associated and that permeates all parts of it. And if you like for a moment to compare a man's future to a battle, in the terms of the battle of life, I can only say, from some experience of battles, that few men, if any, did better in the war in South Africa than the men who came from Lancashire. Of all the vivid recollections that I shall carry to my grave, one of the most vivid is the recollection of the splendid way in which, at the battle of Spion Kop, at which I happened to be present, the Lancashire Fusiliers and the York and Lancaster Regiment conducted themselves. That is the spirit which pervades the whole county, and belongs to the traditions and history of this county, and I think a man starting a profession starts it well when he starts it with the grand records and memories behind him which must always cluster around the county of Lancashire. On these occasions it is the custom to give an address, and I have ventured to choose as my subject to-day what I may term the modern "Religio Medici." Some 260 years ago an English physician published to the world a profession of his faith. The physician was Sir Thomas Browne, and the book which embodied his confession was "Religio Medici." The writer was a man of unusual culture, whose learning had been acquired at Oxford, Montpellier, Padua, and Leyden. It is memorable that this famous book was produced at the very commencement of the writer's career, and it may be well for those who are just now entering upon the profession of medicine to consider what is now, at the dawn of the twentieth century, the faith of the physician. There is much in the "Religio Medici" which is personal to the man who wrote it, there is a little which would be unacceptable to the modern physician; but there remains a not inconsiderable part which rests upon unchangeable foundations, and which is beyond criticism. The elements of that creed would appear to concern themselves with two great issues, with the general attitude of the medical man towards disease, and with his particular attitude towards the sick whom he will profess to treat. In the days of Sir Thomas Browne a conception of disease was current which still influences the minds of many, although that conception should have vanished with the advance of scientific knowledge. The old idea of disease was that it was a malignant entity, a something vaguely individualised as evil in origin, evil in intent, and evil in effect. It was the roaring lion going about seeking whom he may devour. The conception went further, and made of disease a Prince of Darkness vindictively hostile, and potent only for ill. His minions fell upon the land like a hideous blight, and covered a smiling country with the shadow of death. Primitive people regarded disease as the work of a malignant spirit who entered into a man, and who was to be propitiated by gifts and flattery on the one hand, or driven out by the beating of tom-toms, or by strident incantations on the other. To the author of "Religio Medici" disease was still the outcome of an influence which was outside the body and quite distinct from it. There was nothing natural in any of its processes, and nothing beneficent in any of its manifestations. It followed from this that every symptom of disease was of necessity regarded as wholly noxious, and as needing to be stamped out with unconsidered violence. If the patient vomited, the vomiting must be stopped; if he coughed, the cough must cease; if he failed to take food, he must be made to eat. Not for a moment could it be considered that there was any benevolent purpose in these phenomena.

(a) An Address delivered at the Opening of University College, Liverpool, on Friday, October 10th, 1902.

The physician of the present day cannot include this conception among the articles of his faith. In the new "Religio Medici" this matter of belief must follow some such lines as these:—The human body is highly organised, is frail, is finite, and is, of necessity, prone to decay and dissolution. It grows, its reaches its maximum power, it declines, and its capacities fail. In the progressive enfeeblement, and in the slow elimination of the evidences of life which attend old age there is nothing preternatural, and nothing which can be considered to be due to other than the simplest natural influences. The inherent decay of the human body renders it liable to accident, and there is no reason why it alone—of all other organic structures—should be exempt from injury. The body also—like other living fabrics—is prone to be infested by parasites, and upon the action of these parasites very many maladies depend. Not only is there nothing preternatural in disease, but it is the outcome of natural processes, and, more than that, there is evidence to show that many of its manifestations and of its methods are marked by a purpose, and that that purpose is beneficent. The time has come when it would rather appear that many of the so-called symptoms of disease are expressions of a natural effort towards cure, that they are not only not malign in their intent, but they have for their end the ridding of the body of the very troubles which they are supposed to represent. There was a time when the manifestations or symptoms of tuberculosis were regarded as products of a malicious evil which had no purpose beyond that of doing harm. Modern pathology, however, teaches that the so-called symptoms of tuberculosis are the expressions of a beneficent process which has for its end the cure and not the destruction of the patient. The body is invaded by a parasite called the tuberculous bacillus. Such invasion may be regarded as accidental. No symptoms and no discomfort indicate the act of infection. The phenomena which follow, and which are styled the "symptoms" of the disease, are no other than attempts on the part of the body to drive out the invader and restore the individual to health. Changes take place in the invaded part—let us say the lung—which are wholly beneficent and which have for their purpose the elimination of the parasite. Upon the efficiency of the inflammation induced in the tissues the life of the patient depends. Inflammation is, under all conditions, a benevolent process, the purpose of which is cure. Portions of the invaded lung may be destroyed and infected, and damaged tissue expelled; or the inflammatory process may effect the inclusion and safe isolation of the invading host. If the name "disease" has to be employed in the old sense, then it should be limited to the act of invasion, and "disease" in this particular instance has no symptoms. As another example may be cited the case of a man who accidentally wounds his finger. But for inflammation and suppuration every neglected septic prick would be fatal. The ancient surgeon who endeavoured to exorcise inflammation as if it were the vilest of evil spirits was directing his wrath against the most benevolent of angels who was ever entertained unawares.

This matter may be followed out a little more in detail in connection with the symptoms of the disease familiar by the uncouth name of appendicitis. In this malady a trouble occurs in the appendix. The wall of the little tube becomes perforated, and an acrid poison finds its way into the sensitive cavity of the abdomen. This, at least, is the essential calamity in many instances. The perforation is sudden, is accidental, and may be preceded by no warning sign of any kind. Here again the disease proper may be without a single symptom. The manifestations which follow the perforation are termed the symptoms of peritonitis. They are distressing and urgent, but they are all benevolent in intent, and are the outcome of Nature's vigorous effort to minimise the calamity and save the patient's life. The intense pain and collapse impose upon the victim absolute rest, and, more than that, enforce rest in the most advantageous posture, that, namely, of recumbency. He is rendered helpless at a moment when any movement may be attended by disaster. The sickness and the utter nausea which attends it secure some emptying of the alimentary canal, and forbid the introduction of any fresh material into an intestine which is best placed for recovery when it is least occupied. The skin of the abdomen becomes acutely sensitive, and so protects the damaged parts from disturbance and pressure, and this most necessary end is further secured by another symptom—the remarkable rigidity of the abdominal wall. Even should the affected area be accidentally pressed upon the firmly contracted muscles which cover it will shield it like a protecting cuirass. Thus is brought about that state of absolute rest which is essential as the very first step towards the repair of the injury. At the same time the condition of the circulation is so modified as to render absorption of septic matter from the affected district as little ready as possible. Within the abdomen the manifestations of peritonitis are appearing. Peritonitis has commonly been spoken of as one of the most deadly and most malignant of calamities. Never was a condition more unjustly abused. The phenomena of peritonitis should be hailed with thankfulness. Peritonitis is concerned only in effecting good. It is in every instance a beneficent process. It is Nature's method of bringing about a cure, and is successful in millions of instances. But for peritonitis every intra-abdominal wound and a multitude of intra-abdominal lesions would be inevitably fatal. So far as the abdomen is concerned peritonitis is the great life-saving process, and should its possibility be denied to mankind, the human race would be threatened with extinction. There is, indeed, no terror in peritonitis, although a world of alarm may well attend the calamity that calls it forth. Its mode of action is admirable in its simplicity. It induces an immediate paralysis of the ever-moving intestine. With the cessation of these now most dangerous movements the essential state of rest is secured. More than that, it pours out a plastic lymph which glues adjacent coils of bowel together, and in an incredibly short time isolates and encloses the damaged area. It forms a barrier around the seat of the mischief, and upon that barrier the life of the patient depends. An abscess forms, but, thanks to an active peritonitis, the matter contained therein is shut off, is rendered for the time innocuous, and is placed in a favourable condition to be discharged from the body. In actual truth, peritonitis is the operating surgeon's best friend. He who condemns it is like the man whose house is in flames, and who execrates the torrent of water which is poured upon the burning fabric. It would appear, therefore, that the creed of the physician should render his attitude towards disease the opposite to that which was current when Sir Thomas Browne wrote his thesis.

Many of the symptoms of disease, instead of being pounded out of the body by violence, as wholly pernicious, should rather be regarded as means for guiding the physician in the treatment he should adopt. Treatment has to be for the most part imitative of natural processes, and the imitation is founded upon the much-abused symptoms of the malady concerned. The man who swallows a poison is sick, and the treatment which best suffices in such a case is the fullest development of that symptom, namely, the washing out of the stomach. The abscess tries to find a way of escape, and the surgeon's knife but carries out the suggestion forced upon him by the evident intention of the pus. The cough which is so marked a feature in bronchitis tends to rid the bronchi of material which must needs be got rid of, and the physician, acting upon the hint, promotes such elimination. The difference between the old creed and the new in this particular of treatment is well illustrated by the treatment of aneurysm. As soon as an aneurysm has reached certain proportions a clot is found to be forming in it layer by layer. The surgeon who first approached the operative treatment of this condition advised the cutting out of the clot. He regarded the clot as a malignant product because he considered all the phenomena of disease to be malign. Indeed, he went so far as to consider the laminated clot to be the cause of the whole trouble, and therefore he advised that it should be excised at all costs. A later pathology thought that the clot formation represented Nature's method of cure, and that in it lay the saving of the patient's life. The modern surgeon, therefore, not only does not disturb this product but he adopts every measure to ensure its formation. The most successful treatment of aneurysm, indeed, professes nothing more than an encouragement of a natural process, and is based upon the imitation of a prominent symptom of disease. In peritonitis, as has already been pointed out, the pain and tenderness suggest the treatment by absolute rest, the vomiting the treatment by starvation. In ulceration of the cornea the eye closes and a discharge of tears flow over the globe. The treatment imitates this in so far that the eye is kept at rest, light is excluded, and the part is washed by a warm sterile solution.

The second great element in the Religio Medici concerns the relation of the physician to his patient, and here there is probably but little divergence between the old faith and the new. Those principles which should guide a medical man in his conduct towards his patients are few and simple, and the most conspicuous of them would appear to range themselves under three heads.

In the first place, he who adopts the profession of medicine should be strong. His strength must depend upon the fulness of his knowledge of his adversary and of the tactics his opponent may employ. It is not the strength of crude force, but it is that excellent power which depends upon a fine and cultivated sense, a quick perception, a ready judgment, and a delicate susceptibility. It is not the strength needed by the man who wields a bludgeon, but rather that which guides the deft hand of the fencer. It must not be assumed that the education of the physician can be founded exclusively upon text-books and treatises, even when it is supported by work in the laboratory and at the bedside. In the accomplishment of the most learned physicians there may be one thing lacking, the need of which may stand between him and the fullest equipment for success, and that one thing is a tactful and sympathetic knowledge of his fellow man. Indeed, it is not too much to say that the highest qualifications of the practitioner of medicine are not to be represented by any university degree nor discovered by any system of inquisition.

In the treatment of the sick a certain profession of dogmatism is essential. The sick man will allow of no hesitancy in the recognition of his disease. He blindly demands that the appearance of knowledge shall be absolute, however shadowy and unsubstantial may be the bases of it. Moreover, the sick man in his weakness looks to his doctor for the supporting hand and the strong arm; he is moving in the dark and he needs to be led; he is haunted by apprehension and his fears must be allayed. It is this succouring of the weak, this guiding of the feeble, which represents that which is most noble in the profession of medicine. This great privilege, this kindly power, is the heritage of all who embrace the healing art, and it is the possession, of all others, upon which the influence of the physician is based. The second need in the equipment of the medical man is absolute fidelity. All those who profess to attend upon the sick undertake a solemn trust which needs to be observed with punctilious care. The sick man must place implicit faith in his doctor or no faith at all. The fulness and simplicity of this confidence are the measure of the scrupulous honesty with which it must be received. In accepting the trust every physician takes upon himself a grave responsibility, and he who is the most exact in the right observance of this confidence has the greatest claim to be worthy of his calling. The burden of such a trust is little appreciated beyond the confines of the medical profession, and every physician of any experience has had to learn with some bitterness how much self-denial and self-effacement this trust implies, how little the responsibility of it is appreciated, and how much injustice to the doctor its honest acceptance may involve. The public are apt to talk glibly of "medical etiquette," and to assume that it is founded upon some special code of ethics, and based upon a system of morals especially constructed for the advantage of the medical profession. Such criticism is unjust, as criticism usually is which is based upon imperfect knowledge. It is needless to say that there is no precept in "medical etiquette" which is other than the outcome of the simplest justice, the simplest right doing, and above all the truest care for the interests of the patient.

The third article in such part of the "Religio Medici" as bears upon the qualifications of the physician is this—he must be kind. He must needs be a man of wide sympathies, and possessed of that rare qualification which enables him to put himself in the patient's place. There need be little art in this. Genuine sympathy cannot be assumed, or, if assumed, its artificiality is too apparent to deceive even a child. In the mere treatment of the sick a simple kindliness of heart is an essential factor, and it can never be replaced by any assumption of manner, however elaborate, or however precisely mimicked.

In conclusion, I would say that those who are about to enter upon the arduous career of medicine can keep no better motto before their eyes than this: *Fortiter, Fideliter, Feliciter.*

THE FIELD OF VIEW OF THE ANÆSTHETIST. (*a*)

By RICKARD W. LLOYD, L.R.C.P., Edin.

Anæsthetist to the West London and St. Mark's Hospitals
Lecturer on Anæsthetics at the West London Post-Graduate College.

I propose to give some account of the field of view of the anæsthetist, and of the physiology of the systems which it involves, and in doing so give me leave to mention here and there points on account of their general interest, although they may at first sight appear irrelevant.

The respiration may be heard, the respiratory movements may be seen and felt. The force of the expired air may be felt too. The complexion is a guide as to the efficiency of respiration and the condition of the circulation, and in estimating the latter the pulse is useful, as well as being some guide to the depth of anæsthesia. The state of the pupil of the eye, the presence or absence of conjunctival and corneal reflexes, the condition of the muscular system as to its relaxation, and that of the skin in regard to its moisture, are useful in some circumstances, and when there is doubt may be assuring or otherwise.

A favourable result of a survey of the phenomena in this field will generally depend first upon a due performance of respiration which is liable to many kinds of interruption, and the anæsthetist has to steer clear of, remove or control, any untoward condition that may occur to the patient, *e.g.*, nervousness, resistance, holding the breath, crying, laughing, talking, shouting, accumulation of secretions or other matter or materia in the airway or its neighbourhood; respiratory obstruction such as may arise from falling back of the tongue, spasm of the glottis, or other muscles above it; resistance, struggling, general muscular spasm, coughing, vomiting, pallor, cyanosis, failure of respiration, which may be due either to respiratory or circulatory causes, and in this connection it is to be remembered that asphyxia may depend not only upon any of the numerous possible causes of the deprivation of oxygen or the excess of carbonic dioxide in the respiratory medium, but it may be induced by arresting the blood supply to the medulla oblongata, as shown by the Kussmaull-Tenner experiments, or by producing universal anæmia by large hæmorrhage.

The anæsthetist should see that the patient is kept sufficiently warm; that there is no constriction to interfere with respiration, and that no one engaged in the operation nor any bystander is leaning upon the patient's chest. He should be practically familiar with methods of artificial respiration and other procedures for resuscitation in the event of failure of the patient.

(*a*) Abstract of Presidential Address delivered at the West London Medico-Chirurgical Society, on October 3rd, 1902.

The rhythmical functions of respiration and circulation, and all the principles involved, are controlled by the nervous system, which is dependent upon the effect of a due performance of the functions of respiration and circulation for its power of control.

Respiratory movements are entirely dependent upon the nervous system. They are presided over and controlled by the bilateral respiratory centre situated above the vaso-motor centre in the medulla oblongata, which is brought into relation with the muscles of respiration by efferent nerves, the most important of those concerned in ordinary breathing being the phrenic and intercostal nerves. The circular muscles of the bronchi and bronchial tubes are supplied by motor fibres running in the pneumogastric nerves. The tubes are narrowed by the artificial excitation of these nerves. The respiratory centre is also related by afferent nerves, the most important of which are the vagi, but almost any afferent nerve may powerfully affect the centre, and it is also influenced by fibres passing to it from the higher parts of the central nervous system. Of all the sensory nerves in the body the vagi are the only ones whose section produces a marked and permanent change in the respiratory rhythm. Rosenthal showed that section of both vagi made respiratory movements deeper and less frequent. The amount of air taken in during a given time being unaltered, as the alteration in depth and frequency frequently balance each other. Division of the vagi has been performed by every physiologist who has investigated the innervation of respiration, but with varying results. Rosenthal's is the typical effect. In many cases, however, the issue may be quite different.

Consideration of the processes associated with respiration throws much light upon the conditions arising during the inhalation of irritating and anæsthetic vapours, *e.g.*, ether, chloroform, &c., which excite interruption or irregularity of breathing, swelling (it may be mentioned here, for instance, that excitation of the lingual and glosso-pharyngeal nerves dilate the vessels of the tongue while stimulation of the hypoglossal nerve causes them to contract), and spasms of muscles about the air passages, excessive secretion of mucus, saliva, &c., the entry of contents from the stomach into the airway; the altered condition of the blood arises partly from interference with respiration, which is influenced by causes that may be either voluntary, the result of irritation of the air passages by the anæsthetic, or the result of the entry of the anæsthetic into the blood and its effects upon the nerve centres and upon the heart and vessels, or a combination of all of these. More will be said of this later, after considering the circulatory organs, &c., and when enumerating the conclusions of certain experiments.

The irritability of the respiratory passages varies in different individuals and at different times. It is generally increased under emotional circumstances, as when commencing to inhale an anæsthetic, but the amount of cough will depend greatly upon the anæsthetic chosen, in the different circumstances and the manner in which it is introduced. Suddenly inhaling a strong vapour of ether or chloroform is likely to excite cough, and may be a sensation of choking or suffocation. The inhalation of these vapours excites in different patients a variable and sometimes large quantity of saliva and mucus, a viscid mixture, which becomes frothy through being beaten up, as it were, with the respired air, and ultimately adheres about the airway, causing irritation and more or less obstruction of it, giving rise to cough, cyanosis, asphyxial conditions and their depressing consequences, associated often with profuse sweating. Ether is more prone to give rise to those symptoms than chloroform; not infrequently there is little trouble in continuing ether after the first accumulation has been got rid of by removal or swallowing. Keeping the head on one side will often allow the secretion to get into a position where it may cause less and inappreciable irritation or escape. This viscid mucus is often swallowed in considerable quantity, and frequently gives rise to post-anæsthetic sickness.

When cough arises during the early stages of anæsthesia, whether due to irritation or secretion, or both, it is advisable to manœuvre for a deeper anæsthesia which will overcome the coughing. In the later stages of anæsthesia, and when the operation may have been some time in progress, there may be a very excessive amount of secretion preventing efficient respiration, and in that case the secretion may be sufficiently removed with a swab, on a holder or on the tongue forceps, or it may be more advantageous, if there is no reason to the contrary, to allow the patient to come round to some extent temporarily, when he will cough and get rid of the secretion. It may be advisable if ether is being used, in extremely troublesome cases of this kind, to change the administration of ether to that of chloroform, after first clearing away secretion.

In asphyxia, when the vaso-motor centres are directly stimulated by the venous blood the antagonism is still better marked; the cutaneous vessels are widely dilated and engorged, the face is livid, but the abdominal organs are pale and bloodless (Heidenham). The blood pressure rises rapidly, reaches a maximum, and then gradually falls as the vaso-motor centre becomes paralysed. Two factors may be distinguished in the blood pressure—the hydrostatic, due to the weight of the column of blood acting on the vessel, and the hydrodynamic, which is due to the work of the heart. And the influence of change of posture on the circulation is almost completely compensated by the control exercised by the vaso-motor system. In paralysis of the vaso-motor centre by $CH\,Cl_3$ the compensation is destroyed and the circulation may be profoundly influenced by position; elevation of the head may lead to cerebral anæmia, syncope, and even death; elevation of the legs, and particularly the abdomen, may restore the sinking pulse by filling the heart and vessels of the brain.

Owing to these influences it is not until a quarter of the blood has been withdrawn that there is any notable effect upon the pressure, for the loss is quickly compensated for by an increase in the activity of the heart and a constriction of the small arteries. The proportion of blood to body weight in an infant is 1-19, in an adult 1-13. An animal may recover after losing considerably more than half its blood. It is not usually possible to bleed a dog from its carotid of more than three-fourths of its blood. In introducing blood or saline solution into the circulation these compensatory influences are reversely at work, and an addition of 50 per cent. may not cause any marked increase of pressure, and the circulating fluid of an animal may be almost doubled without causing death.

During an operation the quantity of blood in the patient varies for practical purposes, not only by reason of the hæmorrhage that takes place, but also with the situation of the remaining blood and consequent supply to vital organs. The quality of the blood is of much importance, and this as well as the quantity possessed by persons about to undergo an operation varies, and is often below the standard of health.

Vomiting may occur before, or during the administration of an anæsthetic, from various causes, including emotional ones, or be excited by the sense of smell, or taste, or it may depend upon direct irritation of the respiratory or alimentary passages, by the anæsthetic vapour, or be set up by irritation due to excessive secretion, or be the result of the effect of the anæsthetic upon the nervous and circulatory symptoms. It frequently occurs if the depth of anæsthesia is allowed to lessen before the patient has arrived at the depth of surgical anæsthesia, or when the anæsthesia is passing off during or after an operation—in other words, when the patient is "coming round." It is more frequently associated with some operations than others, depends largely upon individuality, and may in many cases be avoided by thorough preparation of the patient by diet, rest, and aperients. It is generally associated with some faintness, may be excited by movement or change of position, and probably never occurs during deep anæsthesia.

The conditions which influence the size of the pupil will account for its behaviour during the administration of anæsthetics, not being constant or uniform. A contracted, a medium, or a mobile state of the pupil is satisfactory. In the early stage of chloroformisation the pupil should be contracted, but a dilated pupil may be observed sometimes in the early stages of general anæsthesia, although it is commoner in the later stages and, I believe, constant in the dangerous conditions in which death is impending, unless influenced by drugs, *e.g.*, opium, or pathological conditions such as adhesions, or disease of the nervous system. A dilated pupil is a signal (not necessarily of danger) to the anæsthetist to make doubly sure of the exact condition of the patient. While respiration and circulation are effectually proceeding, a widely dilated pupil soon contracts on temporarily discontinuing the anæsthetic. Besides the conditions referred to it may be evidence of excess of anæsthesia or exhaustion from shock or hæmorrhage, and is frequently observed as a precursor of vomiting. A contracted pupil is always reassuring unless produced by drugs, *e.g.*, opium or morphia, or by disease. While administering an anæsthetic, I have occasionally observed the pupil of a patient undergo some contraction and a corresponding amount of dilatation synchronously with respiratory movements.

Dilatation of the pupil while administering chloroform may arise from various causes, but when it is due to too high a percentage of chloroform in the system it is perilous to ignore it. Suppose a patient to be breathing very shallowly or to stop breathing, conditions which may occur early in an administration or temporarily under some circumstances from what has been said, when there may be no danger. But if also the pupil be dilated and there be a livid pallor of complexion, you are face to face with a fatality unless the condition is recognised and corrected. It is a moment when the living aspect of the patient may be changing to one of death, when the vital functions are arrested or nearly so, and one which severely tries the judgment, nerve, and resource of the anæsthetist.

The corneal reflex is more sensitive than the conjunctival, and during the administration of an anæsthetic the former may be present while the latter is absent. Both are absent when surgical anæsthesia is complete, and I have exceptionally known them to be absent in quite the early stages of anæsthesia, and before anæsthesia is complete, so that their absence is not an infallible guide to the anæsthetist in this respect.

[Mr. Lloyd here introduced the conclusions of Dr. Embley and Prof. C. J. Martin, of Melbourne, drawn from a long series of experiments on animals, and published in the *British Medical Journal* April 19, 1902, and of which most are hereunder reproduced.]

“Summary of Conclusions of Dr. Embley's Experiments. (*a*)

“1. Heart muscle is very sensitive to the poisonous effects of chloroform.

“2. Chloroform raises the excitability of the vagus mechanism, particularly in the early part of the administration. The increased excitability of the vagus mechanism is due to the action of chloroform on the centres. The inhibitory action of the vagus is more intense and fatal in its effects, from being exercised upon a heart whose spontaneous excitability is diminished by the action of chloroform upon it. Chloroform vapour, not stronger than 1·5 per cent., in the air administered to morphinised dogs, after a period of mild excitation, slowly depress vagus excitability. Above 2 per cent in the air inhaled may occasion dangerous or persistent inhibitions in dogs.

“The failure of many experimenters to recognise the importance of vagus inhibition of the heart, appears to depend upon the fact that the inhibitory mechanism was paralysed or exhausted by the previous induction of chloroform anæsthesia before the records of the experiments were commenced. This especially applies to the Hyderabad Commission and Richet. A dog becomes, in fact, quite another animal after the induction of chloroform anæsthesia without morphine: from being an animal with a very sensitive vagus control of the heart, he becomes one almost wholly devoid of this function, that is, if he lives through the induction. Consequently vagus inhibition from chloroform alone, or from chloroform and asphyxia combined, or from reflexes arising from surgical procedures, are difficult to demonstrate in dogs so prepared.

“Similarly the inferences of the Hyderabad Commission, with respect to the time relations of cardiac and respiratory failure, although true for their experiments, do not necessarily apply for animals in which the vagus mechanism, the cause of sudden circulatory failure, is not exhausted. They did not take any records of the induction period of chloroform anæsthesia, the period in which the vagi are active.

“The fall of blood pressure has been shown to be largely due to the direct effect of chloroform upon the heart. Heart failure begins with the fall of blood pressure All blood-pressure tracings, those of the Hyderabad Commission as well, show that this precedes failure of respiration.

“Richet, on the other hand, and curiously enough from results obtained from experiments performed upon animals with similarly exhausted vagi, concluded that clinical deaths never result from failure of respiration. The recovery of vagus function after the depression resulting from the induction of chloroform anæsthesia is slow, and I wish to emphasise the fact that transient recovery, followed by reinduction, does not represent the conditions of a primary induction.

“Section of the vagi or atropinisation of dogs, absolutely abolishes sudden heart arrest from chloroform. The heart under such conditions fails slowly with rapid pulse, slowing as the blood pressure approaches zero. Under these conditions the respiration fails when the blood pressure falls sufficiently, and invariably long before the heart stops. The vagi of dogs vary considerably in their relative excitability and endurance. This constitutes the important personal factor in dogs. Vagus inhibition is, in dogs, the great factor in the causation of sudden death under chloroform.

“3. The central medullary vaso-motor system is stimulated, at any rate for a time, by chloroform. Oncometer experiments show that the net result of chloroform on the vessels of the spleen, bowel and kidney shortly after the commencement of inhalation is dilatation. The effects of chloroform on the peripheral mechanism is paralytic, and on the central vaso-motor system is stimulative, so that the effect on the intact animal is some algebraic sum of the increased stimulus reaching the muscle cells, and of their diminished power to respond. At the very beginning of inhalation the second factor may predominate.

“Gaskell and Shore found that when chloroform was delivered to the brain alone, vascular constriction ensued, and they concluded that chloroform did not paralyse the vaso-motor centres. Hill, on the other hand, found that when chloroform was delivered to the intact animal vascular relaxation ensued, and inferred that vaso-motor paralysis occasioned it. My experiments demonstrate that the results of both of these investigations are correct. They further show that Hill's results were from peripheral and not central paralysis, and that the amount of vascular relaxation that Hill demonstrated was the resultant of these two opposing factors. There appears nothing to justify the assumption of Dastre that vascular constriction is a result of the administration of chloroform.

“The cause of the fall of blood pressure from the administration of chloroform is paralysis of the muscle cells of the heart and of the arterioles, the fall may be further augmented by slowing of the heart's rate.

“4. Failure of respiration in inhalation experiments is mainly due to fall in blood pressure. With a good blood pressure, failure of respiration by inhalation of chloroform is practically impossible. Restoration of respiration is dependent upon restoration of blood pressure. Failure of respiration occurring in the induction or early period of anæsthesia happens as frequently after as it does before the heart stops.

“I have emphasised the fact that the chances of dangerous vagus inhibition in chloroform administration are greatly increased by imperfect respiration; (2)

(*a*) This summary of conclusions is part of the papers that appeared in the *British Medical Journal* this year (April 19) by Dr. Embley, Hon. Anæsthetist to the Melbourne Hospital.

that respiration fails when the blood pressure falls greatly from cardiac inhibition or other causes.

"In these two series of phenomena we have material for the formation of a vicious circle; for example, supposing (as happens in some cases) that from the inhalation of too strong vapour of chloroform cardiac inhibition occurs, this occasions (1) dangerous fall of blood pressure; (2) cessation of respiration, and the asphyxia consequent thereupon itself increases the inhibition. Or supposing (as happened in some other cases) the administration of too strong vapour occasions by its direct action upon cardiac muscle a rapid fall of blood pressure. This is followed by cessation of respiration, and the ensuing asphyxia is very liable to produce sudden and often fatal inhibition of the heart, which, of course, still further depresses the blood pressure.

"I do not wish to discuss the practical application of these results at present, but one obvious moral is, use only weak vapour of chloroform (less than 1 per cent.) in the early stages, until the initial increased excitability of the vagus mechanism has given place to diminished excitability; in other words, take time in "putting the patient under."

Mr. Lloyd continues:

The consideration of the amount of anæsthetic absorbed and its effects are all-important to this subject. By way of illustration the degrees of anæsthesia and calculations of Dr. John Snow, the author of the first classical work upon the subject, entitled "On Chloroform and other Anæsthetics," published in 1858, are interesting. I will briefly place them side by side:—

Degrees of Anæsthesia.

1st degree. — Consciousness not abolished, disturbances of special senses and sensibility.	Snow calculated that it was necessary that the blood of an average adult patient should contain twelve minims of chloroform to produce his 2nd degree of narcotism.
2nd degree. — Mental functions impaired, not suspended.	
3rd degree.—Voluntary movement suspended, involuntary movement continuing.	Eighteen minims of chloroform for the 3rd degree.
4th degree.— Breathing stertorous, pupils dilated, muscular system relaxed.	Twenty-four minims of chloroform for the 4th degree.
5th degree.—Respiration failing profoundly, sometimes only diaphragmatic, then ceasing, and soon the heart also, as in death from asphyxia.	Thirty-six minims of chloroform in the blood for the arrest of respiration.

The Committee appointed in 1864 by the Royal Medical and Chirurgical Society found that atmospheres containing from 2 per cent. to 4 per cent. of chloroform vapour were attended with little or no risk to life, that 5 per cent. were sometimes necessary, and that stronger atmospheres induced alarming symptoms.

The following table of 839,245 chloroform and ether administrations, collected by Dr. Julliard, of Geneva, shows their relative frequency of administration and death-rate:—

Anæsthetic.	Total Number of Administrations.	Total Number of Deaths.	Death-rate.
Chloroform ...	524,507	161	1 in 3,258
Ether	314,738	21	1 in 14,287

Statistics prepared by different observers vary, and although it is proverbially said that statistics may be made to prove anything, still there is an overwhelming majority in favour of ether in all of them.

Dr. Embley's conclusions are such important results of very much work, and his references are so comprehensive, that I did not hesitate to quote them word for word.

Admitting his statement that "section of the vagi or atropinisation of dogs absolutely abolishes sudden heart arrest from chloroform." The former is not applicable as a preliminary to human surgery. Under the influence of atropine, which is itself a poison acting in varying degrees upon different individuals, chloroform is not wholly robbed of its lethal properties by the action of the atropine, and the question arises whether, during the administration of chloroform in practice, the chances of restoration would be increased if, through unforeseen circumstances, a condition arose calling for artificial respiration, &c., in an atropinised patient.

In experimental work chloroform appears to be the anæsthetic usually selected. Ether is generally more favoured than chloroform by those clinical anæsthetists who do not limit themselves to one anæsthetic. It is to be admitted that chloroform has the advantage of ether in some cases, *e.g.*, in administering ether to some patients it is impossible to obtain a deep enough anæsthesia to cause muscular relaxation without danger, which is shown by laboured and embarrassed respiration and increasing and extreme cyanosis while the administration of ether is continued.

It is a fact, too, that the administration of a little chloroform to a patient who is recovering from that cyanotic condition that has been brought about by ether, causes the patient to rapidly pass into a state of muscular relaxation and surgical anæsthesia without undue cyanosis, and giving little or no anxiety. It is not always possible to recognise with certainty the patient that will present those symptoms, but when they occur under ether they soon pass away on discontinuing that anæsthetic, and then a very little chloroform is sufficient to establish surgical anæsthesia, and it is remarkable how well chloroform suits patients with whom ether disagrees in that way.

Some complicating symptoms arise oftener while administering one anæsthetic than another. Some of those symptoms are attended with more danger than others, and similar symptoms arising in association with one anæsthetic are less dangerous than when arising with another. For instance, any untoward symptom arising during the administration of chloroform is more dangerous than a similar symptom arising during the administration of ether. Not only that, but dangers from chloroform are more insidious than from ether, display themselves more suddenly, and produce a condition in which the vital functions are more profoundly in abeyance, and their restoration necessitates efforts more prolonged and more doubtful of success.

The consideration of normal physiology is essential in regarding the physiological effects of anæsthetics. Chloroform has been the subject of many inquiries conducted in laboratories by individuals, committees and commissions, resulting in views with some of which all investigators agree, while in others there is great diversity of opinion. These results, derived from experiments upon animals, valuable and important as they undoubtedly are, do not embrace all the clinical difficulties of the anæsthetist, whose human patients have higher sensibilities, and are generally anæsthetised without selection, or preliminary drugging or tracheotomy to obtain respiratory freedom. In the accounts of laboratory experiments there is generally no reference to the difficulties always met with, more or less, in anæsthetising man, namely, those referred to early in this paper, and which are sometimes embarrassing enough to restrain a timid, or to lead to failure or catastrophe in the hands of a rash, administrator. The important clinical factors, loss of blood and operative procedure, too, are generally omitted, or play no part in the experiments. Animals are sometimes unintentionally lost in experiments, *i.e.*, die by "misadventure," or "while under the influence of the anæsthetic," and if it were not that the experiments are often intended to terminate with the death of the animal, it is likely that the records of such accidental deaths would be larger.

I believe the safety of anæsthetics will be increased, that strenuous efforts to that end will be continued, and that it is impossible to absolutely eliminate all risk under all circumstances from such potent agents in human hands.

THE NICOTINE QUESTION IN SMOKING.

HABERMANN'S RECENT ANALYTICAL RESEARCHES AND EXPERIMENTS.

By Prof. STRANCH, M.D.,
of Vienna.

[*Specially Translated for* The Medical Press and Circular *by Dr. J. G. ad Goelz, Pontypridd.*]

Just as the deadly nightshade contains atropine, and the poppy morphine, so does the tobacco plant contain nicotine as an active poison; it is its specific poisoning substance, which it alone can prepare.

A yellowish fluid, easily volatile, of disagreeable taste, it itches on the tongue, excites to vomiting, and acts chemically as a strong alkali. It is volatile, hence it easily passes through the mucous membrane of the mouth, stomach, and intestines. Having arrived in the stomach it meets with cells of peculiar construction, with which it brings about chemical combinations, whereby it first excites these cells to increased activity, and then leaves them paralysed. These are the nerve-cells which build up the brain and spinal marrow. The consequences, which such a disturbance or destruction of the little wheels in the human organism is able to bring about, are termed symptoms of poisoning; in the worst cases it means death.

I may be allowed to mention a few of these symptoms. The heart is to the fullest extent adapted to all demands; when we run, perform gymnastics, or exercise ourselves in any way, the muscles of the body exert themselves most, and consequently must be provided with a more plentiful supply of nourishing blood. This is done forthwith by the heart: it beats quicker than before, and so performs increased work. If, on the other hand, we lie still in sleep, the need of blood for the organs is at a minimum; the heart then works slowly, much slower than during the daytime.

The order for increasing or decreasing the activity is transmitted by a special, automatic nerve channel—the *nervus vagus*. Now, this nerve is just one of the many vulnerable points liable to be attacked by nicotine. It becomes excited, sometimes even paralysed, but this only in cases of severe poisoning. The consequence is that the heart is no longer able to adapt itself to its functions, as the regulator of its activity has got out of order. This shows itself, accordingly, in a weakened or hurried pulse, with palpitation, difficulty in breathing, &c., as immediate consequences.

In the spinal marrow high up in proximity to the brain lie the cells which control the action of breathing. Should these become paralysed by the poison, breathing would cease at once, and that would mean death to the affected person through suffocation.

Formerly, when nicotine and the tobacco plant were still extensively used in the medical practice, such fatal cases may doubtless have happened owing to mistakes. Nowadays, however, cases of nicotine poisoning, as a consequence of excessive tobacco smoking or chewing, come rarely under medical treatment.

The question now arises, what part does nicotine play in our different modes of enjoying tobacco, more especially in the case of cigars, of which alone I shall treat in the remainder of this article.

First of all, let us trace the process of development of the cigar. A tobacco-leaf, plucked from the plant, and dried forthwith, looks like tobacco, but it is quite unsuitable to our taste, even the Havana variety. In order to make the leaves fit for smoking, they must undergo a process of fermentation. To this end they are piled up in the moist state in heaps of from one to five tons, and are then left to themselves for several weeks. In this way the bacteria, mould-fungi, &c., which are found plentifully on the leaves, are given the opportunity for an enormous increase.

The result is a partial destruction of the plant substance, and certain bodies appear as secondary products of the activity of these minute, but powerful and skilful chemists, which give to the prepared tobacco its peculiar flavour. Moreover, the entire heaps become considerably heated; a temperature of 60° C. even has been registered in the interior of such a heap—a sign of the violent energy developed during the fermenting process.

The entire circumstances are analogous to those which bring about the spontaneous combustion of hay, for in this case too, most probably, mould fungi are the primary cause of the evolution of heat.

The process of fermentation imparts, as observed, to the cigar manufactured in this way its flavour; and, indeed, a specific flavour, for a Mexican cigar tastes very differently from the Havana article. The speciality is to a great extent due to the properties of the fermenting organisms, and, considering the great variety of the bacteria flora, this is not to be wondered at. The fact itself is of great practical importance, for it points out a means of improving poor qualities of tobacco, viz., by "inoculating" them with germs from better kinds. Yet the fact remains unaltered, that the best cigars are obtained from the best classes of raw tobacco.

During fermentation the amount of nicotine is reduced by about one-half. Thus it appears very unlikely that we smoke tobacco for the sake of the nicotine. It would otherwise be acting very irrationally to lessen the amount of the desired substance by what is, after all, the secondary and unessential process of making it palatable. The supposition becomes still more improbable when we learn that the finest sorts of tobacco contain ·5 to 2 per cent. nicotine, while the inferior kinds have from 2 to 8 per cent. calculated upon the dry state. In addition, it should be mentioned that, in accordance with the analyses of tobacco-smoke (*i.e.*, inhaled smoke) treated in the following paragraphs, the amount of nicotine contained in the Austrian "Regie-cigar," of almost all kinds, whether mild or strong, was found to be about the same, independent of the proportion in the cigar.

In order to arrive at a conclusive decision physiological experiences should suffice. There are few poisons to which the system can accustom itself more quickly than nicotine. A rabbit that is to-day just able to survive the effects of a certain amount of the poison, will require, a few days later, a considerably larger quantity of the poison in order to produce symptoms of the same intensity. If the poisonings be only carried on often enough, this can easily be brought so far, that the rabbit can, without inconvenience, take an amount of nicotine that would kill directly a normal animal. Applied to the human constitution this means that the smoker, who at first gets sick after one cigar, will soon be able to smoke several with comfort.

As I have already said, there is no direct, and probably no indirect connection either, between the "strength" of a cigar and the amount of nicotine it contains. I take the following data from an experiment performed in this connection.

A Manilla cigar, marked as particularly strong, sold for 1½d., contained 1·192 per cent. nicotine; a mild "Importé," on the other hand, contained 2·241 per cent. It must therefore be considered as purely accidental if an Austrian, strong "Regie-Virginia," has also yielded 2·96 per cent. as its maximum percentage. The fact that a so-called "nicotine-free" cigar contained, none the less, 1·37 per cent., *i.e.*, more than the above-mentioned "Manilla," need not interfere with its harmlessness in other respects.

What really constitutes the strength of a cigar is so far, entirely unknown as a chemical factor, but will in all probability have to be looked for in the products that come into existence during the fermentation of the tobacco leaves, and which, as such, or in an altered form, mix during the combustion of the cigar with the inhaled air, producing in this way the effects of poisoning.

I may be allowed to add a few more words with regard to the changes the cigar undergoes while being smoked.

As the cigar smoulders away slowly, under a comparatively slight development of heat, no flame arising only the products of incomplete combustion appear, and among them, without doubt, are those unknown chemical bodies which impart the aroma to the smoke. Among the products of combustion accessible to chemical research, carbon dioxide and carbon monoxide, which latter is the cause of poisoning by charcoal fumes, take the first place in point of volume.

By means of an ingenious apparatus, which exactly copies the action of smoking, J. Habermann has recently succeeded in collecting and classifying the different gases in the smoke of Austrian Regie cigars.

The following data are taken from his interesting treatise. The experiments were so conducted that, by means of a pumping apparatus a measured quantity of air was sucked through the lighted cigar, and at such a rate that the cigar quietly burned to the end. The combustion of the cigar passed off therefore exactly as if a smoker had kept it alight in the usual way. If the pump worked too slowly the cigar went out. In this manner it was possible to fix, for each sort of cigar, the necessary amount of ventilation. Now the question arises, what becomes of the nicotine, of which the cigar contains a considerable quantity. Being a volatile fluid, it cannot exist in this state at a high temperature, but passes over into the gaseous form. It therefore evaporates in the glowing part of the cigar, and, as nicotine vapour, is carried off along with the inhaled air, to mix with the various gases of the tobacco-smoke.

Now during the analysis Habermann found again in the smoke one-sixth to two sixths of the quantity of nicotine the cigar had originally contained. This is, therefore, the quantity to which it is believed poisoning effects may be ascribed. If we translate these figures into practice, we arrive at the following calculations:—A cigar of the Porto Rico kind weighs about 4 gr. It contains ·05 gr. nicotine, of which at most one-third, say, ·02 gr. is absorbed by the smoker. But as the cigar end must be deducted from this, the quantity is reduced to ·015 gr. Of this quantity, 15 milligrams, not more than one milligram enters the system of the smoker, and that is practically nothing.

As I have above observed, only a small fraction of the nicotine passes off in the smoke, the remainder is accounted for in two ways A small portion cannot escape combustion, by which it is more or less altered, at all events it is changed into substances which are no longer nicotine. The other portion undergoes the following changes. The vaporised nicotine finds itself receding from the "glow-zone," the farther it gets the less are the conditions fulfilled which are requisite for its continued existence in the gaseous state; in other words, when the nicotine vapour reaches the cooler part of the cigar, it condenses again into a fluid, and remains thus dormant. The small portion of nicotine which escapes this repeated condensation, is the same portion, which later can be observed in the smoke.

The part where the vapours thus condense, namely the cigar end, is therefore considerably richer in nicotine than is warranted by the amount of unconsumed tobacco. In accordance with this Habermann found, during the analysis of the cigar end, that its contents of nicotine and nicotine-like substances, were from 20 to 100 per cent. more than could be expected from the contents of the whole cigar.

A considerable number of other fluid substances were also found in the cigar smoke, such as pyridine—the fluid by means of which methylated spirits are made unfit for drinking—sulphuretted hydrogen, and perhaps also some prussic acid.

If now, we ask again, on what does the strength of a cigar depend, the number of substances which have to be considered can be considerably lessened. Carbonic acid and nicotine, as well as the minute quantity of sulphuretted hydrogen, may be left out of consideration to start with. There remains the group of pyridine-like bodies; among which, of course, there may still occur some most violent poisons—prussic acid, for example, which, being an extremely active substance, is able to produce its symptoms of poisoning even when present in very small quantities; and finally there is the carbon monoxide.

Indeed, it is extremely improbable that any single substance is accountable for the strength of a cigar; most probably a great many contribute towards it whose respective quantities will vary in each cigar, depending however, on the form of the cigar, the amount of moisture, the rate of smoking, and many other factors. Owing to these considerations a clear decision of the question is very remote. For the present we must be satisfied with the knowledge that nicotine has not by far the dangerous signification which is commonly attributed to it.

Berlin Clinical Lectures.

THE
DIAGNOSIS AND TREATMENT OF GASTRIC ULCER.

By Dr. EWALD,
Of Berlin.

I shall confine myself to the study of gastric ulcer from the point of view of a diagnosis, leaving on one side the therapeutical aspect of the question. In the first place, I cannot agree with the opinion of M. W. van Ijzeren, who is inclined to think that the cause of ulcer of the stomach is due to spasm of the pylorus, an hypothesis which appears to me very improbable, since in the majority of cases no such spasm is present; I think we have here an instance of confusion between cause and effect, for we know that hyperacidity of the gastric juice occasionally produces tonic spasm of the pylorus, even in the absence of any ulcer.

Statistical data furnish but few facts likely to be useful in respect of diagnosis. I have investigated some 1,080 cases of gastric ulcer during the last ten years. By classifying these cases according to sex and age, I obtain much the same results as other authors, and I may say the same of the mortality.

With regard to the physical symptoms of gastric ulcer, I do not hesitate to introduce the sound, in order to confirm a doubtful diagnosis; but as a rule I abstain from its use in cases in which there is no room for doubt. In the presence of profuse hæmorrhage I think, however, that we are justified in employing the sound and in irrigating the mucous membrane with iced water, but only for therapeutical purposes.

I have been struck by the large number of cases of gastric ulcer not presenting any hyperacidity. I noted hyperacidity in only 56·8 per cent. of the cases. I observed on several occasions great fluctuations in the degree of the acidity, which oscillated between 28 and 44, 36 and 78, 38 and 54, 29 and 75, &c. The point is one of great importance in cases in which the ulcer subsequently underwent cancerous degeneration. Lactic acid was always absent in my cases. Long bacilli were also often absent.

The gastric juice of many of my patients contained blood, although the vomit was not blood-stained, and although the contents of the stomach presented no particular characteristics. Hæmatemesis was observed in 203 cases out of 304 (125 men and 78 women). The value of this symptom in the differential diagnosis is very great, but we must make quite sure that, in a particular case, the loss of blood is not of another origin. I may call attention particularly to three sources of error: vicarious menstruation, hæmorrhages due to grave septic infection, and parenchymatous hæmorrhages.

I cannot accord to hæmorrhagic erosions the status of a morbid entity. My own observations, particularly in respect of the gastric juice obtained by means of a tube, and also in the fragments of mucous membrane which came away in the water used in irrigation, lead me to the conclusion that we here have to do with accessory lesions of no particular importance, which heal rapidly, or possibly the early stage of round ulcers, which later on run their usual course.

For twenty years we have made no progress from a diagnostic point of view in the localisation of gastric ulcer. We can only guess, except when we find a tumefaction of the pylorus, the symptoms merely enabling us to suspect the existence of a round ulcer. The differential diagnosis must bear upon (1) the pyloric spasm, (2) a muscular hypertrophy or a cicatricial tumour, (3) a cancerous neoplasm.

There are cases in which it is practically impossible to form a definite opinion, even after minute histological examination, whether we have to do with a slight lesion or a malignant growth. I had two patients in whom, after extirpation of an apparently innocent stricture, the microscopical examination having failed to reveal any cancerous stricture, yet a few weeks later cancer developed. I have elsewhere drawn attention to the fact that malignant tumours are propagated in the mucous and sub-mucous tissues, well outside their apparent limits, and these peculiarities increase the difficulties of the radical operation.

The pain in round ulcer is far from being always typical, especially in cases which run a chronic course, when they are easily confused with gastralgic manifestations from other causes; this is particularly the case in respect of gastralgia associated with the first stage of phthisis, or even in incipient tabes, but I have also remarked it in hernia of the linea alba, which, as I have pointed out on several occasions, may lead to errors of diagnosis, the pain attributed to a round ulcer sometimes disappearing after the hernia has been operated upon.

Loss of flesh and cachexia are comparatively rare in gastric ulcer, and are only observed in nervous subjects, or in obese persons, who have taken less food on account of the pain. In such cases the loss of flesh may render the diagnosis doubtful.

Hypertrophy of the lymphatic glands is only of secondary importance. The state of the tongue is much more important; in cases of ulcer of the stomach the tongue is generally red, moist, with little, or not at all furred.

The complications of gastric ulcer may become the source of very great trouble. Perforation into the abdominal cavity is generally easy to diagnose. Nevertheless, I was once led into error in a case of perforation of the appendix, accompanied by profuse hæmatemesis. We have no means of discovering whether perforation is imminent. The sooner an operation is performed the greater is its chance of success; but the difficulty of the operation may be enormous if the ulcer is extensive, and if the perforation occurs in the centre of a large ulceration.

Among the "chronic" complications of gastric ulcer may be mentioned hour-glass contraction of the organ. In addition to the usual symptoms (the impossibility of withdrawing a large quantity of the water injected, gurgling restricted to the pyloric region, and unilateral distension when air has been pumped in), the diagnosis may be facilitated by the introduction of a thin india-rubber balloon having the shape of the stomach, which is filled with air when in position; this balloon only distends the cardiac end of the stomach, whereas insufflation dilates the whole stomach.

It is often impossible for us to ascertain whether the ulcer has involved the neighbouring organs; at other times, on the contrary, the symptoms are evident (perforation into the pleura, into the pericardium, sub-phrenic abscess, perforation into the large intestine, &c.). The secondary lesions may be mistaken for years for functional neuroses; this is particularly the case in the event of peri-gastric adhesions. The diagnosis must be based on the anamnesis (round active ulcer), on the fact that the pain is always limited to the same spot on the proportion of hydrochloric acid being increased or diminished, and on the existence of vomiting unaccompanied by gastroectasis.

An operation has often cured patients who were supposed to be suffering from manifestations or from over-acidity or gastric catarrh.

In young chlorotic subjects a diagnosis is often impossible; we should then try the effect of treatment for gastric ulcer, a treatment the effects whereof are *nil* in neurotic cases, but very manifest if we have to do with an organic lesion.

I will not dwell upon the differential diagnosis of pyloric and duodenal ulcer, and inflammatory conditions of the biliary canals (gall-stone, tumours, &c.). I need only draw attention to the fact that in all cases in which the stomach is not directly involved the gastric juice is generally normal in character. Moreover, reflex neuralgia is sometimes of great value in arriving at a diagnosis; they occur when a gall-stone becomes impacted, and are met with in the intercostal spaces, in the scapulæ, often diffuse and periodical, they remind one of a latent intermittent fever, or congestion of the liver. Even then the surgeon is very often the first to throw light on the subject.

Ulcerations of the œsophagus are rarely the cause of errors of diagnosis; the localisation and nature of the pain and œsophagoscopical examination enable us to discard them: the same may be said of tumours or inflammatory affections of the lower part of the œsophagus.

With regard to the anatomical diagnosis of the gastric ulceration (a simple ulcer or even—an infinitely rare thing—tuberculous, syphilitic, diphtheritic or uræmic ulcers), this can be arrived at by the course of the affection. We must ascertain whether the ulceration is primary, or whether it has been developed in the course of another affection; moreover, in such case the ulceration remains latent; and is of anatomo-pathological rather than of clinical interest.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Meeting held Friday, October 10th, 1902.

Mr. Howard Marsh, President, F.R.C.S., in the Chair.

The President inaugurated the session by some remarks on the various ways in which new lines of work might be opened up for the society, which, he reminded them, was established for the furtherance of clinical science, based on direct observation and analysis of cases. He pointed out that medicine was not necessarily an inexact science since it was founded on biology, but there was this difference, that while astronomy and similar sciences worked on firm ground, that of medicine was ever changing. He admitted that progress might appear to be slow and by no means commensurate with the amount of energy and time spent in research work. He observed that the modern scientific mind tended in the direction of exact knowledge by direct observation as distinguished from their former knowledge, which was largely empirical. He mentioned that it had been suggested that it might be well to submit certain subjects of current interest to a sub-committee, who, after full discussion in the Society and adequate investigation, would give an authoritative opinion thereon.

Drs. Leonard Guthrie and Frederick E. Batten made a communication on

UNILATERAL ATROPHY OF THE OPTIC NERVE ASSOCIATED WITH HEMIPLEGIA OF THE OPPOSITE SIDE.

Three cases of this rare condition were described, and were to be distinguished from those in which atrophy of the optic nerve was bilateral, descending and dependent on damage to the optic tract on one side of the brain Here, the atrophy of the nerve was unilateral, ascending.

and due to injury of the nerve itself by occlusion of the ophthalmic artery or one of its branches similar to the blockage of the middle cerebral artery, which caused hemiplegia of the opposite side,

The first case was that of a woman, æt. 25, anæmic, and subject to headaches. Sixteen months before admission to hospital she had a fit during the night, and next day she was paralysed down the right side and had lost the sight of the left eye. On admission, twelve months later, she was still hemiplegic, and the right side and the left optic disc was completely atrophied. The heart and urine were normal. She died after being in hospital three months, during which she suffered severely from left-sided headaches, vomiting, and fits of Jacksonian type affecting the right side. At the autopsy occlusion of the left middle cerebral artery was found, causing atrophy of the convolutions supplied by that vessel, together with atrophy of the left optic nerve. The degeneration could be traced back into the left optic tract and also across the chiasma into the right optic tract, whilst the right optic nerve showed no degeneration, in accordance with the fact that a lesion of one optic nerve gives rise to ascending degeneration in both optic tracts. The occlusion of vessels in this case was probably thrombotic, and due to anæmia.

Case II.—A boy, æt. 12, fractured his left femur in October, 1900. In February, 1901, after union of the fracture was complete, he had a febrile attack of doubtful nature, which lasted about a week, and was associated with pain in left thigh. No cause for the pain could be discovered. A month later he became gradually partially paralysed on the right side. In May there were slight signs of optic neuritis (retro-bulbar) in the left eye and vision was very defective. In June the left optic disc was atrophied. By October, 1901, the hemiparesis had entirely disappeared, but the atrophy of the disc remained, although vision had improved. The boy was anæmic, but showed no evidence of endocarditis nor of rheumatism. Partial thrombosis of the left middle central artery and of some of its ophthalmic branches was probably the cause of the symptoms. As in Case I., the symptoms at one time were suggestive of new growth in the left central hemisphere.

Case III. was a woman, æt. 22, who had three eclamptic seizures nine days after giving birth to a child. After the third fit she became hemiplegic on the left side. Several fits, apparently without local inconvenience, occurred during the following three months. They then ceased. Three months after the first fit the woman found that she was almost blind in the right eye. When she came under observation four months later the left arm and leg were in the condition of hemiplegic mobile spasm, and there was atrophy of the right optic disc, which suggested to Dr. Rayner Batten the existence of post-retrobulbar neuritis rather than embolism of the arteria centralis retinæ. Her urine and heart were normal, and she showed no evidence of syphilis. The conditions might have been caused by embolism or thrombosis of the right middle cerebral artery and of its ophthalmic branches. Other cases of somewhat similar nature were enumerated, and the pathology and anatomy of the condition were discussed. It was concluded that unilateral atrophy of the optic disc, associated with hemiplegia of the opposite side, were suggestive of a vascular lesion.

Dr. **Alexander Francis** (Brisbane), introduced by Dr. Greville MacDonald, read a communication on the

NASAL TREATMENT OF ASTHMA.

The association of asthma and nasal disease had been noticed by various writers from the earliest times, but the general opinion among physicians at the present day seemed to be that little hope of obtaining permanent relief of asthma could be got from nasal treatment even in cases where nasal lesions were found. Most rhinologists, on the other hand, had faith in the local nasal treatment of asthma where obvious trouble exists, but none had suggested the advisability of treating the nose in cases of asthma when the organ was apparently normal; and yet, in the author's opinion such were the cases where the most hopeful prognosis can be given. Of the 402 cases here recorded, 346 had no apparent nasal lesion, and of these eight only obtained no relief from nasal treatment, while six cases were relieved by treatment, among fifty-six, which had polypi or other gross nasal lesions. (In addition to these failures, in seventeen cases the result of treatment could not be ascertained.) From treating these cases he had come to the following conclusions:—(1) That asthma is due to reflex spasm of the bronchial tubes; (2) that the irritation may originate in the nose. This is inferred from the intimate association between hay fever and asthma, as disclosed in various cases, and is shown more clearly by the immediate onset of asthma after certain injuries to the nose, examples of which he mentioned; (3) that asthma is not directly due to any mechanical obstruction of the nasal passages, and is not commonly caused by any gross nasal lesion. The association of asthma and polypi is not so common as is generally supposed. When they occur together he believed them more probably the result of some common factor, than that they have any causal relationship. The best results in his polypus cases had been obtained by cauterising the septum without touching the polypi, whereas in some cases the complete eradication of the polypi had intensified the asthmatic condition. In other cases where nasal obstruction from engorged turbinates and asthma occurred together the difficulty of breathing through the nose and the dyspnœa were unrelieved by rendering the nasal passages mechanically free, but were both instantly removed on applying cocaine to the septum; (4) that some part of the nasal apparatus has a controlling influence upon the respiratory centre, or there is in the nose, as it were, an agency through which the afferent impulses must pass. Many cases were mentioned, in illustration, where cauterisation of the septum had completely removed, up to the present time, all sign of asthma in patients where the exciting irritation was apparently gastric, cardiac, or bronchial in origin. Some of these cases were of many years' standing and of great severity.

Record of Cases.—Total number, 402 cases. *Nature.*—Nose apparently normal 346, polypus 32, other gross lesions 24 cases. *Results.*—Complete relief obtained 194, complete relief till lost sight of or still under treatment 30, great improvement 73, great improvement till lost sight of or still under treatment 50, temporary relief 20, slight relief 4, no record 17, no relief 14 cases. Males 282, females 120.

Dr. **Greville Macdonald** observed that in respect of a paper of this kind one was much more influenced by the name of the author than by the text, and this led him to remark that he had known the author from his earliest professional career as a conscientious and careful worker, one moreover who would not make a statement without adequate foundation. They were familiar with the intimate relationship between nasal disease and asthma, although opinions thereon varied very greatly. He admitted, however, that he was quite at a loss to explain the remarkable results recorded by the author. The sensitive areas of the septum had received his own careful attention in connection with hay fever and asthma. He referred to the case of a woman who had suffered greatly from asthma. She presented a polypoid state of the anterior end of the middle turbinal which was snared, since which time she had not suffered from asthma, although the septum had not been touched. In another case, in which the patient, æt. 27, was described as "a wreck from asthma," the removal of a large spur on the septum was followed by relief for four years. Even more remarkable was a case sent to him by Dr. Aveling, that of a boy in whom removal of adenoids was recommended for the relief of asthma. His brother, in examining the naso-pharynx, provoked free hæmorrhage and the operation was deferred, but the lad suffered no more from asthma. He thought these cases were quite inexplicable on any theory whatever. What he always expected to find was anterior hypertrophy of the turbinals and if that were removed he would expect to cure his patient. The paper would make him approach the treatment of cases of asthma in future with more hope of affording relief.

Dr. **Scanes Spicer** thought the balance of opinion was in favour of these intra-nasal operations giving relief in asthma, but he would not go so far as to use the term "cure." His own experience was that the galvano-cautery did not always give such marked relief as in the author's hands except when there was boggy swelling. He thought that an important factor in the production of asthma was a hyperæmic state of the nerves of the nose behind an obstruction, a point to which attention was first clearly called by Drs. A. H. Smith and Bosworth, of New York.

Dr. Burney Yeo, alluding to the author's observation that cauterisation of one side of the septum afforded relief on the same side of the chest, asked whether it led to the disappearance of the moist rales in the common class of cases of bronchial asthma in which there was more or less marked bronchial catarrh.

Dr. Herbert Tilley said he had been "absolutely astounded" by the author's statements. He recalled that after the publication of Hack's paper in 1884 there had been a period during which intra-nasal operations had a great vogue, yet at a discussion on the subject in which many eminent authorities took part only nine cases were mentioned in which asthma had been relieved by intra-nasal measures. He himself suffered from asthma, and he had been freely cauterised without relief. In a family of asthmatics under his observation the cautery had not done good in any one instance; he had also removed spurs, &c., without relief. He might sum up his experience by saying that when he undertook nasal treatment for the relief of asthma he always felt that he was not likely to add to his reputation. If, however, there were gross lesions, he would suggest the propriety of operating to the patient in the hope of obtaining relief.

Dr. Dundas Grant echoed the astonishment expressed by the last speaker, although in his own experience he had often seen relief follow treatment of some gross nasal lesion in asthmatic subjects, of which he gave several examples. Many, however, had not been benefited thereby.

Dr. Francis, in reply, explained that he had been led to the discovery by chance, so that the treatment was purely empirical, and he did not pretend to explain its action. He did not think the particular kind of asthma affected the value of the treatment. He related instances in which the relief was confined to the lung on the same side of the body as the cauterisation, the patients stating that they felt as if something had been loosened along the lower border of the ribs.

PARIS, October 11th, 1902.

THE TREATMENT OF CONSUMPTION.

The treatment of phthisis, perhaps the greatest plague of humanity, had for many years been more or less neglected, probably on account of the universal belief that that malady was rebellious to all curative remedies. Change of air and symptomatic treatment constituted about nearly all the physician had at his disposition. But of late years tuberculosis has received the particular attention of clinicians, and, with the new scientific light thrown on the origin of the malady, phthisis is no longer considered incurable. The former despair has given place not only to hope but to absolute certainty of arresting the invasion of the microbe, when the affection has been early diagnosed and the subject is not otherwise wasted by congenital or acquired disease.

Within the last few months a series of theses have been written on the subject of the treatment of pulmonary tuberculosis, covering pretty well the ground, and may be regarded as quite up to date. Of these the following is a brief *resumé* :—

THE REST CURE.

Dr. Poussardin insists particularly on absolute rest. Rest, in his opinion, diminishes the accumulation of waste tissue, and favours their elimination. Fatigue on the contrary, constituted a kind of auto-intoxication. The air and diet cure are without result if the patient does not observe rest. By rest digestion is facilitated by leaving the organism to concentrate its strength on assimilation: by rest the nerve influx, which ought to sustain the struggle against the malady, is economised. Consequently tuberculous patients should be enjoined to take one hour's rest at least after each repast in a reclining chair and not sitting up. Besides, rest has a very decided influence on the temperature of the patient, while also by it oppression, expectoration, and hæmoptysis are diminished.

Dr. Berigaud endeavours to prove that the climate of high altitudes, by the absolute pureness of the atmosphere, is one of the best adjuvants to therapeutic treatment, especially in the case of those who are manifestly predisposed to consumption, and in initial tuberculosis of the apex of the lungs, and even where the malady had already developed to a certain extent, provided that the general condition of the patient was strong enough to bear the climate. High altitudes were, on the other hand, counter-indicated where the patient had arrived at the cachectic state.

ALIMENTARY REGIME.

Dr. Rousseau confines himself to the study of the rules of alimentation which phthisical patients should observe. The diet should be substantial but not forced. Useless to tell a patient who has a distaste for all food (anorexia) that he must eat *quand même*, the appetite would come all right. The physician should endeavour to excite the appetite by such things as the patient likes, and by degrees he will bring him round to take a fair diet. Raw meat made into a pulp, eggs, peas, different farinaceous foods should be preferred, milk, képhir render sometimes good services. The menu should be varied almost daily, and care should be taken not to, by an excess of zeal, stuff or overfeed the patient. The gastric juices cannot penetrate easily a large mass of food, and, if persisted in, would produce a dyspeptic condition from ataxy of the stomach.

Useless irritation of the organ should be avoided. Wine or alcohol should be suppressed and the patients recommended to drink pure water. For the same reasons such drugs as creosote, tannin, quinine, &c., should not be prescribed; while the use of condiments should be forbidden, or extremely limited.

MEDICAL TREATMENT.

The fourth thesis, that of Dr. Colombet, is confined to the medical treatment, and more especially to arsenio-phosphorated medication.

Arsenic and phosphorus have been employed for a very long time in the treatment of pulmonary tuberculosis, but in the mineral state. M. Colombet studied the therapeutic effects of these two metalloids associated in *organic combination.* After a series of comparative experiments, he fixed his choice on nuclinic acid, which he took by the method of Meischer from the "milk" of herrings. This acid he associated with methyarseniate of soda, and he submitted thirty-three patients in the hospital to that treatment. A considerable improvement was observed in nearly all the patients; the appetite returned, the fever diminished, as well as the night sweating. Cough and expectoration decreased, and the author noticed a decrease in the number of bacilli; nearly all the patients increased in weight, and about half of them left the hospital to return to their work, alleging that they felt quite strong again. Examination of the physical signs showed a considerable improvement (disappearance of dry and humid rales). The urine was frequently analysed. The elimination of the chlorides underwent no notable change while the loss in phosphates diminished where it had exceeded the normal quantity.

A Hospital Loan.

For some years past the condition of many, or at any rate of some, of the Paris hospitals has been the subject of unfavourable comment. It has now been decided to raise a loan of forty million francs (£1,600,000) to bring them into conformity with modern sanitary requirements. The loan will be floated by the municipality, the hospitals of Paris being maintained out of the rates, and the security will take the form of a charge upon the *octroi* receipts.

Berlin, October 11th, 1902.

The Rational Treatment of Oxaluria.

In the *Therap. et Gegenev.*, 7/1902, Hr. Rosin discusses the subject of oxaluria. His observations on a case —that of a man, æt. 52, with oxaluria—form the basis of the communication. The patient was treated by the method of Klemperer. Before commencing treatment it was ascertained that the urine, normal in amount, was turbid, contained a considerable amount of sediment which contained the well-known crystals, hyaline or finely nucleated casts, and epithelium of varied origin, but no albumen. The patient was now put on the special diet, from which vegetables, especially cabbage and spinach, were excluded, also tea, cocoa, milk and eggs, whilst carbohydrates, roots, fats and fruit, such as apples and pears, were allowed. Fresh meat, which is generally allowed, was permitted only in small quantities on other grounds (arterio-sclerosis, suspicion of contracted kidney). Effervescing drinks were allowed freely, lemonade and small quantities of Epsom salts three times a day. The result was surprising. Even by the end of the first week all the crystals had disappeared from the urine even when this was centrifugated, although they had been present for years previously. When after the end of a month the magnesia was stopped, the crystals still remained absent. The excretion of casts was unchanged, and also the pain in the region of the kidneys.

Case of Cerebral Abscess Simulating Atropin Poisoning.

Dr. A. Aufrecht reports this case in the *D. Arch. f. Klin. Med.*, 72, 5 and 6. The patient, a labourer, had received an injury five years previously, some sacks of sugar having fallen on him. From this time the patient complained of violent pain in the right breast, with which later on asthmatic and anginal attacks became associated. As examination gave a negative result, V. Noorden's atropine treatment for asthma was begun (14·4 mgrms. three times daily). Two days later the man was found huddled up in his arm chair and unable to rise. He complained of headache, was confused, and spoke with difficulty. There were transient tremors of the right arm. The pupils were widely dilated. It appears now, accidentally, as was later on discovered, that the pills contained 0·1 gr. atropine in ten pills, instead of 0·01 gr. The man had only taken two of the pills, and the writer rejected the idea of atropine poisoning some hours later on finding the pupils no longer dilated and reacting normally to light. Nothing particular was observed during the following day, but on the day after convulsions occurred, which lasted several hours. During complete unconsciousness, the left half of the face and the left arm were the seat of violent twitchings; these only ceased after the injection of 0·018 gr. of morphia. In the afternoon the patient was again conscious and complained only of headache. No vomiting, pulse between 66 and 72. In the evening he could not speak a word. (It is to be noted that the man was left-handed.) The next day there was difficulty of swallowing; in the afternoon there was violent pain in the chest lasting for two hours, and also in the right arm. There were numbness and weakness in the left arm, the leg unaffected; difficulty of swallowing; pulse 54, temperature normal; the inability to speak continued; complete paralysis of the left arm, and now the corresponding leg became affected, spasm of the right side of the face lasting an hour. Complete left-sided hemiplegia now came gradually on, loss of consciousness, food could not be taken, and death took place three and a-half weeks after the commencement of the illness. A diagnosis had been made of disease in the right anterior central convolution, the sudden commencement pointing to hæmorrhage.

The autopsy showed an abscess the size of an apple in the right temporal lobe, which reached to the margin of the right anterior central convolution, and had destroyed a considerable portion of it (1½ cm.). The wall of the abscess was completely organised. It was plainly of old date as to origin. The cause must be looked for in the injury sustained five years before. From that time to the onset of the fatal symptoms, no cerebral symptoms had been observed beyond the peculiar oppression, the difficulty of breathing, and the pressure on the chest, which the autopsy showed to be quite normal.

In a case of Gerhardt and Schott an abscess had remained latent twenty-one years, and in one of Hosslin's twenty-six years, and in Nauwerck's case twenty-eight years.

At the Dermatological Society Hr. Hollstein showed a woman, æt. 48, with all the symptoms of

Local Asphyxia and Symmetrical Gangrene

of the finger (Raynaud's disease). Asphyxial attacks occurred, characterised by both arms "going to sleep," "deadness" of the fingers, dark blue colouration of the nails, followed by inflammation culminating in gangrene. Cold appeared to favour the development of these attacks.

Hr. Nagelschmidt reported some experiments on the

Bactericidal Power of the Finsen Treatment.

He rubbed tubercle bacilli into the shaved and scarified skin of guinea pigs, from which an apparently tuberculous inflammation developed. The diseased parts were then subjected to the Finsen light for an hour, when they were cut out, rubbed up, and injected into the peritoneal cavity of other guinea pigs. Some of the animals so treated remained healthy, while certain animals injected with similar material that had not however been subjected to the Finsen process all died. It appeared as if the treatment brought about a reduction of virulence in the germs.

Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, October 11th, 1902.

Pemphigus a Neurotic Disease.

SCHROTTER, at the Congress for Internal Medicine, related the history of a case confirming the view expressed by many in respect of the etiology of this disease. The patient was a female, æt. 59, who was suddenly affected with a troublesome affection of the mucous membrane, resembling pemphigus, which finally developed into pemphigus foliaceous of an acute character. Three months after the onset she died. Along the whole length of the central canal of the spine the ependymal cells were increased with patches of greater intensity and thickening of the tissue. In the upper part of the dorsal section there was a sort of splitting of the tissues with capillary hæmorrhage, the latter occurring more particularly in the grey substance.

Leube said he could confirm this observation by a case of his own, in which pemphigus was undeniably of a neurogenic origin. His patient was æt. 6, and was recovering from typhoid when he suddenly became ill, followed by motor aphasia and pemphigus, with large blisters on the face, ear, &c. Both the aphasia and pemphigus disappeared after eight days.

Tuberculosis and Carbonic Acid.

Weber read a long paper in support of the view that carbonic acid was a cure for tuberculosis; he adduced much direct evidence to support the theory. Tuberculosis of the lung usually commences in the apices when the supply of venous blood is scanty. Hamburger supported this theory by experiment, since he found that venous blood was a potent bactericide, while arterial blood encouraged the growth of bacteria. Bier has also proved in surgery that congestion of the osseous vessels cures tuberculous bone. Again, heart disease is a powerful immunising agent in producing passive congestion and hyperæmia of the lung, thus preventing phthisis. During pregnancy the wasting of the lung is usually checked by a retention of the carbonic acid in the blood. In diabetes, on the other hand, we find that half the sufferers die from phthisis due probably to the elimination of the carbonic acid in the form of sugar.

The production of fat and carbonic acid may be regarded as collateral terms, since phthisis commences with a great and rapid loss of fat, while recovery is heralded by an increase of fat. When diet of easily-burned material is used, such as levulose, there is not only an increase of fat but a large amount of carbonic acid produced, which exerts a specific action on the tuberculous bacilli.

We may conclude therefore that increased nutrition increases the carbonic acid in the system, and thereby acts as a toxin and affords protection. From this reasoning the most rational treatment would be by injecting a carbonaceous fluid, such as paraffinum liquidum purissimum, to increase the carbonic acid.

Rosenfeld thought this form of treatment had neither sufficient theoretical evidence nor practical results to prove its value.

Light on System.

Biè gave a *résumé* of the present views prevailing on the application of the different lights at present in use. Finsen, he said, had used red rays in small-pox, and by its chemical action on the skin had prevented the secondary fever that is occasioned by the purulent vesicle and also prevented cicatrisation. His experiments with the same light on other exanthemata had given negative results.

Backmann and Chattrière asserted that they had got good results with the red rays in measles, while Krukenberg spoke equally well of his results in erysipelas.

Kellogg said he had constructed an incandescent lamp for the hot bath, which he praises, but his results are attributed more to the perspiration induced by the hot bath than by the light.

It is interesting to note here that nationality has something to do with the results. In Russia, for instance, nothing remarkable has been observed. Minin, who is the Russian representative, tells us that he has used both the incandescent and arc lights with no perceptibly beneficial results.

The therapeutic light of the future seems to be the sun bath without subsequent packing, or an electric arc-light bath with a current of from 150 to 200 ampères and without perspiration. We know far too little yet of light therapeutics to dogmatise, Finsen's results on the skin are really all that we have to build a superstructure upon, and these are mostly of a cosmetic character as far as has yet been recorded. The advantages of this treatment are that the surroundings as well as the morbid centre are treated, which may account in some measure for the non-recurrence of the disease, and probably also relieves the contraction that often occurs in other cicatrices, as these are usually soft and smooth.

There are other advantages, such as the absence of pain and a freedom from danger. The curative effect, judging from the results of 640 patients, is excellent; eighty-five of them were perfectly cured for the time being, while 15 per cent. were slightly improved, but not cured.

The results in lupus erythematodes are only of an average character, but the treatment is certainly successful in alopecia areata, nævus vasculosa, acne vulgaris, acne rosacea, and epithelioma cutaneum.

Jaksch dilated on the calming and soothing effects of the blue rays, to obtain which he used cobalt globes for lighting the hospitals at night.

The incandescent baths were void of any good result beyond the benefits resulting from an ordinary warm bath.

Quincke referred to his own experiments with sunlight on active tissue, such as in the formation of pus, where a large amount of acid material was used up. In this condition there is certainly an amelioration of the diseased condition, both subjective and objective, which proves that the light must have a beneficial influence on the metabolism of the organism.

Rumpf spoke in favour of the incandescent hot bath, which he thought was very efficacious at low temperatures for heart affections. The skin is more tolerant of the arc light, and is best adapted for use in health. The arc light acts very efficiently on erysipelas, either with or without the blue disc; this he had frequently found useful in neuralgia.

Hahn thought the Finsen rays were only useful in skin diseases, and more particularly in lupus, but recurrence was not prevented. The action is not bactericidal, but inflammatory. In the arc lamp the ultra violet are the most efficacious rays, and can be best obtained by substituting an iron for the carbon electrode, as in Bang's lamp. All light treatment fundamentally depended on the Röntgen ray, although Finsen's method was sometimes useful.

Marcuse had treated 400 cases with both arc and incandescent for the hot bath, and found the latter the best for heat and producing perspiration. In some cases the heart was affected by it, but it has no effect on obesity.

The arc light is useful in cases of neurosis, but locally it is useless, unless by suggestion. The light therapy is best performed by the solar rays, but at the same time he could not refrain from expressing his own conviction that the whole subject was tainted with charlatanism.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

Operation for Acute Intestinal Obstruction.—Mr. **Battle** operated on a married woman, æt. 33, who had suffered from symptoms of obstruction of the bowels for a period of five days. She first of all complained of pain in the abdomen and in her back, which as it increased in severity became paroxysmal and was accompanied with vomiting. The bowels also were constipated, and she was unable to get any action even with medicine; no relief has been afforded by medical treatment, and for two days the abdomen had become more and more distended; there had been no fever. The history of the case was as follows:—Four years previously she had been in St. Thomas's Hospital under the care of Mr. Battle for appendicitis, and the appendix had been removed through the incision usually employed by him; at the same operation a cyst had been removed from the right broad ligament through an incision in the median line below the umbilicus. Since that operation the patient had enjoyed very good health and had led a fairly active life, sometimes going on cycling excursions. During one of these trips three months ago she was thrown violently from her machine and the handle bar struck her in the abdomen. After this she was laid up with abdominal pain and vomiting, and had to keep her bed for nearly a month. Her symptoms then passed away and had not returned until the commencement of the present illness. On admission to the hospital she was sick and had a somewhat dry tongue, although she did not look greatly distressed. The abdomen was rather distended, and she complained of pain chiefly in the lower part and on the left side. Here there was some tenderness on pressure. She had evidence of free fluid in the abdomen. The scars of the former operations were firm and strong, there had been no yielding, and the one in the appendix region was hardly visible. It was considered that her symptoms arose from the presence of a band which had probably formed as a result of a localised peritonitis following the injury received from the handle of her cycle. At the operation an incision was made through the left rectus muscle and the abdomen opened; there was some free fluid in the peritoneum, which ran out, and a distended coil of small intestine was seen on the left side. This was lifted up, and below it a contracted portion of bowel was seen and a thick, strong, fibrous band crossed the part where this joined, passing from mesentery above to mesentery below; it did not completely obstruct the bowel, and although the gut was marked by its pressure it did not show signs of ulceration or sloughing. It was divided between forceps and a ligature placed on each end. The loop of distended bowel could not be readily returned into the abdomen, so it was punctured with a needle and emptied of its contents, the opening being closed by one or two Lembert's sutures. The uterus was large, corresponding to a two months' gestation. More of the fluid in the abdominal cavity was removed by a sponge and the wound closed. Mr. Battle pointed out that he considered the case was probably one of obstruction due to a band because of the history of injury followed by symptoms of abdominal inflammation three months before. He also regarded the case as one of a subacute character from the evidence of fluid in the peritoneum, this being thrown out from bowel which had not been completely closed. The pain being situated on the left side of the abdomen, and still more the period that had elapsed since the previous abdominal operations, made it improbable that it had anything to do with them. The band was a firm one and more vascular than usual; it was carefully examined to see that it was solid and not a tube, such as stretched Meckel's diverticulum, for he had known a division of a Meckel's diverticulum without proper treatment to prevent escape of intestinal contents from it prove fatal.

The patient made a very satisfactory progress after the operation, but complained of pain in the lower abdomen; a loss of blood from the uterus, which had commenced before admission, continued, and abortion took place a few days later.

Tuberculosis and Lunacy.

In a recent number we drew attention to the alarming prevalence of consumption in our lunatic asylums. At the last meeting of the Metropolitan Asylums Board it was shown that in England for the year 1899 nearly one-fourth of the asylum patients who died were tuberculous, in Scotland one-fifth, and in Ireland one-third. It is generally admitted that a large number of the patients contract the disease after admission to the asylum. It has been proposed that for the consumptive lunatics in the Metropolitan district, Darenth Asylum should be employed exclusively. The matter, we understand, is now under consideration.

The inaugural meeting for the session of King's College Hospital Medical Society will take place on Friday, October 17th, when Sir John A. Cockburn, K.C.M.G., M.D., will deliver an address entitled "Opportunity and Preparation." The meeting will be held in the Operating Theatre, at eight p.m., the chair being taken by the President, L. Vernon Cargill, Esq., F.R.C.S.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 15, 1902.

LONGEVITY IN TOWN AND COUNTRY.

The great practical test of advance in public health is afforded by the life-table of a community. It shows, as most of our readers are aware, the mean expectation of life at each age and for each sex for a given period. It is obtained by taking a million children and following their history through the whole of their lives. It is so arranged as to eliminate errors due to sex and age constitution of the population, and it shows pretty clearly the results of various factors of environment which affect the mortality in different degrees at different ages of life. So far the life table affords the best means of ascertaining the several factors that weigh either in favour of or against longevity. In short, it is one of the most advanced statistical methods whereby it is possible to estimate and record the results of modern preventive methods in the unceasing battle waged by scientific sanitarians against disease and death. As regards London, the first extended life table dealing with its population has been recently issued by the London County Council. It is a valuable document, and covers the decennial period 1891-1900. The deaths of Londoners in the country and *vice versâ* had as a first step to be ascertained, with other precautions and calculations that need not be here entered into. Some of the resulting tables possess the highest suggestive and actual value. The "expectation of life" table, for instance, at certain ages in London, 1891-1900, with those of selected healthy districts, 1881-1890, show that there is still great room for improvement in London mortality. From this table, which appears in the next column, it seems that a male child born in London has a reasonable chance of living for about forty-one years, whereas in a healthy country district he would live probably eleven and a half years longer. At the age of forty-five a Londoner might expect to live twenty years and a half longer, as against the twenty-five years if resident in the more healthy districts. These figures afford an eloquent testimony indeed against the overcrowding of our town populations. An exceedingly valuable comparison is that which compares the expectation of life in London with that of three other towns, and of England and Wales as a whole.

The expectation of a London baby at birth is 40·98 years, that is to say, about two and a half years less than that of the average for England and Wales. A Glasgow baby will live five years less on the average, a Manchester baby six years less, and a Brighton baby nearly three years more. These figures point broadly to a lower standard of environment in Glasgow and in Manchester than in London generally, It is more than likely, however, that the less healthy and more populous districts of London would prove no more favourable to longevity than the environment of towns like Glasgow and Manchester, with their large proportion of poor and of artisan citizens. Brighton is especially favoured by virtue of its position as a seaside town with a well-to-do resident population and an absence of manufactures. As regards London women the average expectation of life at all age periods is now above that of men. Formerly the ratio sank below the male rate during some part of the child-bearing period. Thanks, however, to improvements in midwifery, notably the introduction of antiseptic and aseptic methods, the figures have been changed, so that women have now a better chance of survival at all ages than men. Students of vital statistics will find the recent publication of the London County Council, from which the foregoing facts have been culled, an invaluable contribution to the literature of the subject.

THE "CURE" OF CONSUMPTION.

Much difference of opinion appears to exist as to the justifiable use of the word "cure" as applied to consumption. The hesitancy to adopt it in its customary meaning seems to indicate that the old pessimism regarding pulmonary tuberculosis still lingers; and the scepticism as to the benefits of "hygienic" treatment is by no means dead. Dr. Davies, the Medical Officer of Health for Bristol, in his interesting study of the "Objects and Benefits of Sanatoria," published in his last annual report, dogmatically affirms that "strictly speaking, there is no such thing as cure in consumption. The best that can be hoped for is that the injured tissues will heal up, only a scar being left." But, as if to limit the alarm which might arise from such a startling statement, he adds: "A large proportion of the population of England and Wales are in this condition, and they are able to do satisfactory work for the rest of their lives," and still later we find comfort in the remark that "in a very large proportion of cases the 'cure' is permanent." We do not wish to appear captious, but we think the day has gone by when Laennec's dictum is to be re-stated "L'affection tuberculeuse est comme les affections cancéreuses, absolument incurable." Dr. Theodore Williams we know has repudiated the use of the word "cure," and has proposed that we should not commit ourselves to anything beyond an "arrest" of pulmonary tuberculosis. We venture to think that Sir James Crichton-Browne, at last year's Congress, clearly indicated the opinion of the best pathologists and most experienced clinicians:—"In almost every cadaver there are what may be called the first remains of palæozoic disease; but because we observe in the ileum the obliteration of some of Peyer's patches, we do not say that an attack of enteric fever which happened perhaps forty years ago was arrested and not cured; because we find on the breast a cicatrix marking the site of a carcinomatous tumour removed ten years previously, we do not maintain the incurability of cancer. Then why, I would ask, should the presence of a calcareous nodule or fibrotic patch at the apex of a lung justify us in arguing that phthisis once planted is ineradicable?" We certainly think that the contention of Sir James is both logical and scientific. But we would like to point out that in the eagerness to claim the utmost benefit from sanatorium treatment there is a great danger of using wrong terms. In most instances institutional treatment does little more than secure "arrest" and prepare the way for those reparative processes which in their completion establish "cure." We would suggest that the term "cure" be never applied to any cases until at least two years have elapsed after leaving the sanatorium By some such arbitrary arrangement a certain degree of reliance on sanatoria statistics will then be possible. But in spite of all, the indisputable records of the post-mortem room clearly establish the fact that, taken as a whole, pulmonary tuberculosis is one of the most curable forms of infectious disease.

ARSENICATED TOBACCO.

The deplorable outbreak of arsenical poisoning due to contaminated beer, which startled the whole country some eighteen months since (The Medical Press and Circular, November 28th and December 12th, 1900), not only led to the appointment of the Royal Commission, still slowly collecting evidence, but focussed the attention of the profession and the public on the possibility of arsenic proving an important factor in the production of various morbid conditions. It seems to have been proved that much of the so-called "alcoholic neuritis" —for so long a most common affection in Manchester and district—was really dependent, at least in part, on the presence of small quantities of arsenic in the alcoholic beverages so largely indulged in. "Alcoholic heart," a condition so ably studied by Dr. Graham Steell and other clinicians in the North of England, is said to have become comparatively rare since the malt liquors of the district have been purified of their arsenic. And, as is well known, Mr. Jonathan Hutchinson has collected much data which he holds furnish a strong indictment against arsenic as an etiological factor in the development of "cancer." Attempts have also been made to prove that the mysterious disease known as "beri-beri" was really a form of arsenical neuritis. In showing the shortsightedness of those who have propounded this view, Dr. Patrick Manson has drawn attention to the very serious matter of the arsenical contamination of tobacco. It seems that the Chinese, for instance, not only use arsenic largely in the arts, and sometimes in agriculture, but also very often in their tobacco. Dr. Manson says that he had received samples of Chinese tobacco, to which arsenic had been intentionally added, with the object of giving it a peculiar and much-relished garlicky flavour. The custom is said to be common in China. Now, it is well known that at the present time tobacco is being introduced into this country from all quarters of the globe. Fastidious smokers are insisting on having blends of new and fanciful forms. The artistic names given to many varieties on the market afford but little guide to their origin or manner of preparation. We are not aware that arsenicated tobacco is being widely used, but we fear our worthy analysts have not been in the habit of testing tobacco for this deleterious agent, and we venture to think the Commission now sitting might direct their attention to this matter, and at least furnish us with such evidence as may allay all fears concerning the purity of the much-loved weed.

Notes on Current Topics.

Ascites and Surgery.

Since the original publication by Talma, of Utrecht, of his operation for the relief of ascites due to cirrhosis of the liver, numerous modifications have been suggested by surgeons with the same object in view. Even a moderate amount of success is sufficient to justify operative interference, for there are few conditions more hopeless of improvement by medical means than ascites due to this cause. Dr. Hall White, indeed, has calculated that in cases where the ascites is grave enough to demand tapping, the expectation of life is only sixty-three days. The fundamental assumption of Talma's procedure is that the ascites is due to physical obstruction of the portal circulation, and the method of treatment is to endeavour to relieve the portal circulation by effecting an artificial anastomosis with the parietal vessels. The various schemes proposed have met with a varied success, but certainly the simplest is that recently described by Mr. Peters, of Toronto. (a) His plan is to open into the abdominal cavity, evacuate some of the fluid present, and then, having raised two or three straps of peritoneum from the underlying tissue, insert under each a portion of the omentum. He fixes these by a few stitches, and closes the wound. Mr. Peters has only had an opportunity of testing his operation in two cases as yet, but both have been very successful, although they had been previously treated by repeated tappings without any good result.

Snake-Poisons and Anti-Venin.

At the Malarial Convention held at Nagpur, Captain George Lamb, I.M.S., of the Bombay Research Laboratory, gave a very interesting discourse on the differences between the effects of the *cobra* and *daboia* poisons. A knowledge of these is most important to all who attempt to investigate, or appreciate, the value of Calmette's anti-venomous serum. Indeed, the results of Captain Lamb's researches have given him data which show important differences from those already reported by Martin Cunningham and Calmette. He shows that the action of the cobra poison is primarily, and principally, on the central nervous system. Its activity is secondarily manifested on the blood, of which it breaks up the red corpuscles and sets free the hæmoglobin. On the other hand, the action of the *daboia* poison is mainly, if not solely, on the circulatory apparatus. Its effects are thus tabulated by Captain Lamb:—(1) It affects the coagulability of the blood; injected directly into the blood-stream or in large doses under the skin it so increases this as to cause extensive intravascular clotting. In small doses it causes, after no doubt a short-lived phase of increased coagulability, a marked and prolonged phase of diminished coagulability. So that in some instances I have noticed the shed blood remains absolutely unclotted even after twenty-four hours. (2) It has a destructive action on the red blood cells, breaking these up and setting free the colouring matter contained in them. (3) It has a marked destructive action on the capillary walls, rendering them more permeable to their fluid contents. (4) It has a marked depressing action on the heart, so marked indeed as to sometimes lead to fatal termination from this action alone. (5) It has no action on the central nervous system, and there is therefore no paralysis ever observed. A depressing practical revelation is contained in the fact that Captain Lamb "has demonstrated in many experiments with different animals that Calmette's serum is of no avail whatever in counteracting the poisonous effects of the daboia venom." He also informs us that this serum has little or no effect in neutralising the poison of *Bungaris fasciatus*. So that there is still ample scope for further investigations in this important field for Captain Lamb; and, probably, indeed, for many others.

The Simpler Life.

An interesting correspondence has recently found place in the columns of *The Spectator*, in which the advantages of a simpler mode of living has been graphically portrayed. The life of many a Londoner is encircled by artificialities; the daily round of most citizens is pursued in an atmosphere artificial and enervating; and even in quiet country centres there is much in the environment that is antagonistic to natural existence. Our purpose in drawing attention to this matter is not that we may suggest any radical alterations in manner of life or habit of thought, but to insist on a more thorough probing of the subject than is accorded by the average letter writer. There is a physiological basis for the simpler life, and psychological reasons for a natural existence. Man is capable of wonderful adjustments. His powers of adaptation to environment seems limitless. The reserve force of human vitality cannot well be estimated. Under the most deteriorating influences there is still retained immense power to return to the normal when opportunity allows. Although physiological processes are so complex as to evade all efforts for the complete unfolding of their mystery, yet the maintenance of each in healthy activity is easily procured by the avoidance of inhibitory influences. Hygiene indicates the path of healthy life. A simple life rightly understood is one which is physiologically sound.

Hypnotism—Its Use and Abuse.

Hypnotism, while undoubtedly serviceable in the treatment of certain morbid states, is itself capable of engendering morbid conditions. It is an agent which should only be used by those whose judgment and good faith are assured. The possibility of abuse is generally recognised, and Dr. F. W. Edridge-Green and Mr. E. G. F. Bousfield in the current number of *The Contemporary Review* present evidence to show that there is immediate danger arising from the uncontrolled employment of hypnotism in this country. It appears that advertisements are now appearing setting forth the merits of various courses of instruction which profess to teach "hypnotism," "personal magnetism," "the science of personal influence," and the like. It seems probable that within the last twelve months some thousands of hypnotists have been let loose upon the world. The danger arising from unregulated use of such an agent cannot be overlooked. The time has come when the practice of hypnotism should be carefully restricted, like that of vivisection, to qualified persons only, in whose hands it may be used for the benefit of humanity and not for mischievous purposes.

(a) *Canadian Journal of Medicine and Surgery*, September, 1902.

Sanitary Matters on the Riviera.

FOR long it has been realised that more perfect hygienic arrangements were desirable in many of the towns along the Riviera. On several occasions we have drawn attention to the primitive methods employed in many fashionable and much-frequented health stations. The experience of last season clearly demonstrates the need for reform. We are glad, therefore, to learn that at Nice sanitary improvements have been secured, and that a hospital for infectious diseases has been provided in a convenient but isolated spot in the neighbourhood. If the Riviera seeks to attract visitors it must spare no pains to ensure the best conditions for health.

The Statistics of Chloroform Poisoning.

IT is usual at inquests held on persons who have succumbed to chloroform narcosis, unfortunately of very frequent occurrence, for the Coroner to reassure the jury by giving them to understand that the proportion of deaths is only about one in four or five thousand administrations. It would be interesting to know what authority there is for this statement, especially as the proportions given by medical witnesses on such occasions vary within very wide limits; witness the statement at the inquest at Guy's Hospital last week, when it was put at one in a thousand. The former estimate may be approximately correct in regard to the use of ether, but the mortality from chloroform is certainly much nearer the latter figure, not because chloroform is necessarily a more dangerous anæsthetic, but because it is a more powerful drug, requiring to be used with greater prudence. Moreover, and this is doubtless an important factor in determining the comparatively high mortality, it is the anæsthetic commonly employed by precisely those persons who have least experience in this department, and is, in addition, in the immense majority of cases, given in a rough and ready way on a towel or handkerchief, that is to say, with an absence of precautions which greatly enhances the dangers inseparable from any method of anæsthetisation. Not one practitioner in a hundred understands the use of an inhaler, and this of itself is a sufficient explanation of the fact that it is quite the exception for any inhaler to be used. One of these days the public will awaken to the desirability of imposing greater caution in the use of these beneficent but, in unskilled hands, dangerous drugs. Within the profession opinions, for some reason, are so hopelessly divided as to the proper methods of administration that no uniform and trustworthy method of administration is likely to receive general assent.

Intra-Nasal Disease and Asthma.

ALTHOUGH for years a relationship has been known to exist between intra-nasal diseases and abnormalities and the production of asthma, wide divergence of opinion exists between specialists as to the frequency of the relationship, and especially as to the efficacy of intra-nasal treatment for the relief of the asthma. The apparently contradictory conclusions of those best qualified to judge must be due to the fact that while in some cases marked relief follows treatment of the intra-nasal condition, in others, perhaps the majority, no such effect is observed. But the more we examine the arguments advanced on both sides the greater is the astonishment one feels at the lack of anything approaching unanimity of opinion. Some authorities insist that it is always worth while attempting to cure gross lesions of the nasal passages in the hope of thereby curing the asthma, while others are equally convinced that these coarse lesions are never productive of respiratory embarrassment. To crown the edifice of contradiction, Dr. Francis, of Brisbane, read a paper, which we publish in abstract in the proceedings of the Clinical Society, in which he states that out of 402 asthmatic patients presenting no apparent nasal lesion, eight only failed to obtain relief from cauterisation of the septum nasi. To emphasise the distinction Dr. Francis added that he was most sanguine of curing asthma when the patient presented no obvious intranasal mischief; in fact, when polypi were present he preferred to leave them untouched, directing his treatment only to the septum. Startling as are his results, they are perfectly reconcilable with physiological considerations. It is, indeed, highly probable that some part of the nasal apparatus has a controlling influence upon the respiratory centre; in other words, that it transmits the different impulses direct to that centre, thus standing sentry, as it were, over the respiratory function.

Carbonic Acid in Tuberculosis.

IN view of the doctrine that impure air is a powerful predisposing factor in regard to pulmonary tuberculosis, it is rather startling to be told that carbonic acid exerts a germicidal action on the bacillus. This conclusion is arrived at on the strength of observations which seem to explain the immunity towards the disease which obtains in certain physiological and pathological states on the ground of the comparative richness of the blood in the gas, such, for instance, as pregnancy, heart disease, &c,, while in certain other conditions, such as diabetes, the elimination of carbonic acid in the form of carbo-hydrates creates a proneness to tuberculosis.

It is asserted, moreover, that while venous blood is actively bactericidal in its action, arterial blood, rich in oxygen, constitutes a favourable culture medium. We are hardly in a position to discuss these data on their merits, but we may point out that the presence of carbonic acid in impure air does not prove this gas to be the only, or even the principal, agent in determining deterioration of health. We know as a matter of fact that the damage is done mostly by other organic impurities and emanations. A proportion of carbonic acid which, when associated with organic impurity, is highly detrimental to health, has been shown to be innocuous when separated therefrom. Carbonic acid is taken as a measure of aerial impurity, on account of the facility with which it can be estimated, just as the compounds of nitrogen, though themselves devoid of injurious action, are accepted as the measure of organic contamination of water. If the hypothesis be correct we are invited to accept the conclusion that the rational treatment of phthisis is the injection of a substance rich in carbon, such as pure petroleum; but we prefer to postpone a decision until more ample clinical data are forthcoming.

The Multiplication of the Fittest.

STATISTICAL pessimists profess the greatest concern lest the general intellectual standard of the nation should undergo deterioration in consequence of the indisposition of the more gifted members of the community to marry, and sundry depressing conclusions have been formulated on this somewhat flimsy superstructure. As a matter of fact, statistics do not bear out the premises. An American contemporary has been to the trouble of collecting statistics on this point, according to which the people comprised in the "Who's Who" of the United States marry not only as commonly but as early as the rank and file of the community. Unfortunately, these figures do not cover the whole ground, and do not vitiate the arguments of the pessimists. We are, indeed, less interested in the marriage rate of our intellectual superiors than in their fertility, and this appears to be very low. It is an observation common to all countries that the birth-rate among the higher classes is markedly below that which obtains in the lower social strata, though this does not imply so much a depreciation of virility as an excess of foresight and prudence. It really looks as if Nature had at heart to prevent undue cerebral development by keeping down the standard either by reducing the virility of the intellectual or by endowing them with a prudence which restricts reproduction. We might point out that it is not only highly intellectual people who are thus afflicted. A higher standard of material wealth seems to have much the same effect. In France, for instance, the desire to restrict the benefits of the family estate to one or two children has far more to answer for in this direction than the predominance of cerebral activity.

The Action of Salicylic Medication on the Urinary Tract.

THE renal troubles which occasionally follow the administration of salicylic acid and its derivatives are usually attributed to idiosyncrasy on the part of the patient, but Dr. Lüthe, of Grelfswald, asserts that in every instance more or less mischief is caused to the renal structures by the elimination of the acid. His attention was directed to the subject by observing that a notable proportion of patients taking salicylate of soda developed more or less marked albuminuria, which disappeared on the treatment being suspended. Thereupon he carried out a series of observations on thirty-three rheumatic patients who were taking from forty to eighty grains of the salicylate in the twenty-four hours. In every instance analysis of the urine revealed disturbance of the urinary function, sometimes in the form of albuminuria, in others the presence of white cells and erythrocytes, and in all there was abundance of epithelium from all parts of the urinary tract together with granular or hyaline casts. Crystals of oxalate of lime were also frequently present. The disturbance was in direct proportion to the dose of the drug, amounting, when large doses were given, to actual nephritis, which persisted for some time after the cessation of the drug. Cystoscopic examination of the bladder revealed marked irritation of the vesical mucosa and ureters. The conclusion is arrived at that the use of the salicylates ought to be restricted to acute cases, and that in no case should the daily dose exceed from sixty to seventy grains or be continued for more than four consecutive days.

The Recent Elections to the Pharmaceutical Council, Ireland.

THE recent elections to the Council of the Irish Pharmaceutical Society have resulted in the defeat of the Vice-President of the Society—Mr. J. I. Bernard. This occurrence is all the more noteworthy in that in the ordinary course of things Mr. Bernard would have been President for the ensuing year. It was the direct outcome of an attack upon Mr. Bernard by certain members of the Society, who apparently alleged that he had "identified himself with the common enemy of our profession," that is, with company pharmacists. We cannot enter into the policy of the Pharmaceutical Society regarding company-pharmacy. It is sufficient to say that the law has recognised such a pharmacy, and that unless the Pharmaceutical Society is prepared to go to Parliament to obtain an alteration in the law, it will have to recognise it too. We, however, find it very difficult to believe that Mr. Bernard has acted, or was likely to act, in a manner prejudicial to the best interests of the Society, and accordingly do not think that those members who opposed him have acted wisely. Mr. Bernard was, however, unfortunate in one of his supporters, who took advantage of the *contretemps* to introduce various side issues. Mr. McWalter, the member in question, further threatened to bring the conduct of the Society before the National League if it did not mend its ways. Mr. McWalter may have grievances, and if, as he alleges, it is true that religious distinctions are allowed to influence elections, he has detected a grievance. He can hardly, however, contemplate seeking election to the Council himself, or he would not have shown his hand quite so distinctly.

The Traffic in Old Horses.

The position of the United Kingdom with regard to the use of horseflesh for human food is anomalous and unsatisfactory. It is an open secret that a large amount of horse beef is consumed in London and other large towns, and there is good reason to suppose that a considerable quantity is palmed off on the poorer classes of the community as genuine ox beef. As regards the nutritive qualities and wholesomeness of the flesh of the horse no one can candidly assert that it is inferior to that of other animals habitually used for the food of man in this country. In other words, we refrain from eating horses from reasons that are purely sentimental, that is to say, from simple, sheer prejudice. The man who eats pork and refuses horseflesh would find it hard indeed to furnish any satisfactory explanation of the faith that in him lies. Anyway, it is well known that a considerable proportion of our worn-out horses are sent over to the Continent, where they are boiled down and return to us in the shape of meat extracts. There is no law to prevent either the export of the old horses or the importation of the extract. For all that, our magistrates appear to adopt the most illogical attitude with regard to the practice. They cannot stop this particular export traffic, but they punish heavily for cruelty to animals all persons found taking horses to the knacker's who are known to trade with the Continent. A week ago, in a London police-court, a man was sentenced to a month's imprisonment for sending a lame horse to an exporting knacker's to be killed. If the export trade be not illegal it is not easy to see the justice of vicarious punishment of that kind.

Building Acts and Fire Protection.

The Coroner's inquiry into the recent fatal fire in the City of London appears to be already bearing fruit. One of the points emphasised by the jury was the imperfection of the Building Acts as to the enforcement of proper provision for escape in case of fire. The Act is not retrospective, so that, as the greater proportion of the buildings in the City were built before the passage of the measure, they escape its provisions. The result is that workmen in factories built before 1875 have no such special protection. Then, again, no fire exits can be enforced when a building is sixty feet in height, a restriction which is, on the face of it, indefensible. Under the Factory Acts no provision is made for fire protection if less than forty persons are engaged under one roof. Then, again, instead of making the Factory and Workshops Acts apply to all trades, warehouses, and retailing businesses, its scope is limited to certain manufacturing premises, which in many cases can be defined only after prolonged and costly litigation. As a matter of fact, in practice an immense number of workpeople have absolutely no protection whatever against fire in their place of occupation, owing to the shortcomings of the Act above mentioned. Profiting by the sharp tenor of the recent fire, the London County Council are pressing the Home Office for further legislation to amend the Building Acts, so as to secure control over all buildings; in other words, to make the Acts retrospective. With that additional power, and a reorganised and properly equipped fire brigade, the security of the citizens will be materially increased.

Medical Sauce and Medical Advertisement.

Our attention has been called to the peculiar circumstances under which a sauce is sold to the public under the title of "Dr. Hewitt's Digestive Sauce." The article in question is made by a firm in Farringdon Street, London, and on one side of the bottle is a label with testimonials from four medical men, whose names and addresses are printed in full. Two of these gentlemen, Dr. Gabe and Mr. Sterne Price, live in Mecklenburgh Square, and a third, Mr. W. P. Hollis, in Claremont Square, London. The fourth writes from Ennis, but the name given is not to be found in the Irish list, although there is a Mr. J. Davoren registered in a metropolitan suburb. If the testimonials in question have been published without authorisation, as is doubtless the case, these gentlemen have just cause of complaint against the proprietors in thus thrusting greatness upon them, a greatness strictly comparable with the notoriety which is *not* fame. Some time ago a medical man's name and address was printed on a slip of paper, in connection with a testimonial, and put inside the cover of every tin of biscuits sold by an enterprising firm of manufacturers. Sauce and biscuits are about on a par in their connection with legitimate medicine, for we fear that the addition of the word "digestive" will not suffice to give the necessary professional stamp to the condiment in question.

Unfair Examination Questions.

Certain members of the State Board of Medical Examiners in California have been made the subject of rather violent criticism at the hands of a medical contemporary, on account of the questions which were asked at a recent examination. Our contemporary has no hesitation in openly hinting that the questions were such as could not be answered by any save the pupils of the examiner, inasmuch as the answers to them cannot be found in any standard medical work. Three questions particularly arouse his ire, and we must say that we have no hesitation in condemning them as unsuitable questions to be asked in a qualifying examination, though one hesitates to believe that they were asked with the deliberate intent of favouring certain students, as suggested

The three questions alluded to are "Define cryoscopy," "What is Hanot's disease of the liver," and "Define pollakiuria." Far too many examiners conceive it to be their duty to find out what a candidate does not know, and to entirely neglect any effort to find out what he does know. The former is a much easier process, and, perhaps, it is for that reason so generally adopted by unsuitable examiners. The Californian examiner may well be asked whether, even if candidates were able to answer these questions, they would *ipso facto* be better general practitioners than if they were unable to do so.

The Punjab and the Plague.

The greatest sanitary campaign which has ever been undertaken is that on which the Government of the Punjab have just entered. It is, in fact, the inoculation against plague of the total population, amounting to about ten millions. When one remembers the vigorous opposition shown elsewhere to protective measures by the natives of India, one cannot but wonder at the courage shown in deciding on such a scheme. But it seems no choice was left, for, to quote the Government Report, "there remains only inoculation." It is noteworthy that up to 1900 the Punjab was practically free from plague, while other parts of India were suffering tremendously. In the official year 1899-00 only 510 deaths from the disease occurred, but in the next year the number amounted to more than 6,000, while the last reports shows the huge total of 200,000. Such a rapid increase is unprecedented in the modern history even of this dread disease, and all measures dictated by science, experience, and policy have failed. The Government of the Punjab express the hope that the people will be induced to submit voluntarily to the operation of inoculation, and, presumably, in this expression they embody the opinion of advisers well qualified to judge.

The Early Diagnosis of Jaundice.

The recognition of a slight degree of jaundice is sometimes difficult when the observer has to trust for guidance entirely to the yellowish hue of conjunctiva and skin. Indeed, there can be no reasonable doubt that such cases not infrequently escape detection, together with many others in which no perceptible staining of skin and mucous membranes takes place. At the same time, it is obviously a matter of clinical importance to the physician to ascertain whether a patient has or has not free bile circulating in his blood. The urine often contains no bilirubin in the early stages of jaundice, even when that symptomatic condition is severe and strongly marked. Under these circumstances the method suggested by Dr. Hamel, Assistant of the Berlin Medical Clinic of the late Professor Gerhardt, promises to be of considerable practical value. In suspicious cases he advises an examination of the blood serum of the patient. He fills a small capillary tube with blood from a puncture in the lobe of the ear. After standing the tube, sealed at both ends, for a few hours in a vertical position the serum separates from the blood clot, and can be then examined against the light. Normal serum is colourless, whereas the slightest trace of bile is revealed by a yellowish tint varying in depth with the degree of saturation. This simple test should be useful in determining many obscure points in the action of bile-poisoning upon the human system, especially when the bile exists in minute quantities in the circulation.

Sleeping Sickness.

A severe epidemic of sleeping sickness, or negro-lethargy, has broken out in the Uganda Protectorate, and in the great Lake district of the Nyanza, Kioga, Baringo, Naivispha, and Nahurs fully one-third of the inhabitants are infected. Until 1898 the disease was unknown in the Protectorate. The first notice of sleeping sickness came from Winterbottom: "An Account of the Native Africans in the Neighbourhood of Sierra Leone, 1803." Forty years later Clarke published a series of articles on the subject, giving the classic clinical feature of the disease. The earlier noted cases were found on the low ground of the Bight of Benin and the coast line of Sierra Leone. It now appears that the disease was contracted in the higher grounds, and that its victims made for the sea-coast, just as to-day the negroes of Angola, when infected, make for the important commercial port of São Paulo de Assumpcão de Loando. Sporadic cases are found on the littoral of the Mediterranean Sea, and in the Island de Fernando Po, and in the Ihla da Principe; and a few cases have been reported from British Guiana and from the West Indian Islands. One case of the disease occurred in England, in a negro who was resident in the country for three years, a fact which gives some ground for the statement that the incubation of the disease not infrequently occupies seven years. Dr. Patrick Manson considers that no authentic case of the lethargy has been observed in a European. The lethargy from which Napoleon suffered from 1812 to his death had many of the clinical symptoms of the disease, notably his attack at Dresden. The disease was even more closely simulated in Dr. Foot's patient, who suffered from narcolepsy. The etiology of the disease is very obscure. During the old slave days, when gangs of the natives were driven to the West Coast for sale, nostalgia was credited with being the predisposing cause. Clarke thought that it was due to the excessive smoking of "diarrba," a variety of Indian hemp. The early missionaries looked on it as due to the excessive use of palm wine, a thing which would not account for its prevalence among the Marabouts, who drink nothing but water. It is now described as a meningo-encephalo-myelitis. This view was that of Clarke, who described his autopsies in which he found arachnitis, though Guérin, many years later, failed to find any evidence of such in twenty-three post-mortems. The Government has sent a Commissioner to the affected area to investigate the nature of the epidemic on the site of its greatest activity, and there is little doubt but that the work will result in a permanent and valuable addition to our knowledge of the disease.

Parents' Consent to Operations.

The question of obtaining the parents' consent to operations cropped up again at an inquest at Cardiff on a child who had died in the course of an operation for the relief of dropsy. The mother denied having given her consent, and the Coroner's suggestion that it would be well for surgeons to obtain a written authority before performing an operation an obviously impracticable plan. Moreover, if people place themselves in the hands of the medical officer of a hospital, it ought to be the presumption that they consent to undergo whatever treatment may be advised, otherwise their admission has no *raison d'être*.

Medical Students at Confinements.

At a recent inquest in London on a newly-born child the jury commented adversely on the practice of sending medical students to attend confinements, and despite the statement that it was one of the regulations of the colleges that students should attend such cases, and that such regulation was recognised by the General Medical Council, the jury added a rider to their verdict of natural death that in their opinion none but properly qualified men should be sent to such cases.

On Thursday, October 16th, Sir Victor Horsley is giving an Address before the Reading Pathological Society on "The Value of Anæsthesia as a Localising and Differential Symptom in Injury and Disease of the Central Nervous System."

Dr. Ernest W. White, Professor of Psychological Medicine at King's College, London, has been elected President of the British Medico-Psychological Association.

Dr. Goodhart will give an address at the special general meeting of the Bradford Medico-Chirurgical Society to be held to day (Wednesday), taking for his title "Round About Constipation."

LIVERPOOL.

[from our own correspondent.]

University College, Liverpool — Opening of Winter Session.—The winter session of the medical faculty of Liverpool University College was opened on Friday last, when the distribution of scholarships, medals, and prizes took place before a distinguished audience in the Philharmonic Hall. The occasion was more than usually interesting by reason of the presence of Sir Frederick Treves, Bart. Every part of the spacious hall was well filled. The governing body and teaching staff of the College, accompanied by former students of the medical faculty and by representatives of the staffs of various hospitals, entered the hall in processional order, and took up their places on the platform, headed by the stewards. In this picturesque academic pageant was displayed a bewildering variety of stately and richly-hued gowns, caps, and hoods representing the various universities at which their wearers had graduated. To the music of Mendelssohn's "War March of the Priests" in "Athalie," a singularly appropriate strain for this martial array of scholars clad in the impressive panoply of learning, they moved with the rustling of many gowns to their places. Considerable ridicule has been ignorantly thrown upon mere clothes by a late surgical writer of fame, but the display of Friday last will for ever take away the point from his shafts, cast, as we have said, in his ignorance. Sir Frederick took for his theme "The New Religio Medici," an address which we have the pleasure of reproducing on page 399. After the address, which was listened to with great interest, the Lord Mayor, in proposing a vote of thanks to Sir Frederick, expressed himself as reassured, and Dr. Carter, who occupied the chair, and who seconded the proposition, gave expression to the thankfulness he himself and the faculty felt to the lecturer for the kind and admirable advice given.

"**Fortiter, Fideliter, Feliciter.**"—Much inspiration flows from a wise motto. On reading the address by Sir Frederick Treves, it will be seen that he had been advising the students here to keep their eyes on the above three injunctions when discussing and comparing the old and the new conceptions of disease. But whether we view disease as a malignant entity, evil in origin, evil in intent, and evil in effect, or treat its manifestations as expressions of a natural effort towards cure, suffering and dying patients and weary and discouraged practitioners may well combine something of the stoic and sentimentalist, and gather hope, faith, and charity even from a motto.

BELFAST.

[from our own correspondent.]

Chair on Natural History in Queen's College.—The Chair of Natural History in Queen's College, rendered vacant by the resignation of Dr. R. O. Cunningham a few months ago, has been filled by the appointment of Mr. Gregg Wilson, M.A., Ph.D., D.Sc. Professor Gregg Wilson is a native of Falkirk, was educated at Edinburgh, at Freiburg, was assistant to Professor Cossar Ewart, and lately Inspector of Fisheries for England. He comes to Belfast with, according to the *Scotsman*, the reputation of being a delightful colleague, an enthusiastic worker, and an earnest and successful teacher. Should he see fit in his leisure time to interest himself in the fisheries of Ireland he may prove an acquisition not only to Queen's College but to the whole country.

Royal Victoria Hospital.—The winter session at the Royal Victoria Hospital will open on Tuesday, 21st. This will, in all probability, be the last session in the old hospital, as the new building is rapidly approaching completion, and is expected to be ready for occupation in the spring.

Special Article.

NATIVE MEDICINE IN CENTRAL AFRICA.

The people who occupy the western margin of the broad expanse of the Victoria Nyanza, and the adjoining portion of the tropical area of the Dark Continent, are known by the name of Baganda. Territorially, the Baganda are likely to prove of importance in the future progress of British civilisation in Africa. Ethnologically, they are negroids. Philologically, they are of the Bantu family. Physically, they are a fine race: many of the men stand over six feet in height. Æsthetically, they are graceful, both in figure and movement. Intellectually, they are both willing to learn and quick in the acquisition of knowledge. By intermarriage with women of neighbouring tribes they have greatly improved the general type. Specimens of the heavy, unintellectual negro are much more rare among them than among most other Central African tribes. Those untutored people of the equatorial section of mysterious Africa have, as would naturally be anticipated, many peculiar notions of their own in connection with disease and dissolution. To their primitive comprehension there is no such thing as "natural death." Both sickness and death are, in every instance, the result of the influence of some unfriendly spirit. The afflicted individual may by his own action have evoked the hostility of such spirit; or the malicious activity of the latter may be called into play by some evil-minded acquaintance who bears him a grudge. Their system of prognosis, as well as that of their treatment, is, as might have been expected, one which involves peculiarly complicated details. We owe to the Rev. J. Roscoe, C.M.S., Uganda, special thanks for the interesting information which he has given us on these heads. Whenever a case of sickness occurs the relatives of the patient proceed to ascertain the cause. For this very essential information they apply to the priest or medicine man, who in turn resorts to one of three oracles. He brings out a strip of cow's hide 4 ft. long and 18 ins. wide, which he spreads flat on the ground. He stands at one end, while the suppliant kneels at the other. He has also by him nine pieces of cow (or buffalo) hide, each 4 ins. long by 2½ ins. wide; one of these has a number of cowrie shells stitched on, while the other eight are plain. He has also a stick of 2 ft. in length, with (a natural) crook at the end; with which he hooks his cowrie shells, and draws them towards him after he has thrown them on the leathern slip. When everything is ready for the opening of the performance, the suppliant pays down nine cowrie shells —*nine* is the sacred number in Uganda. He then states the case for which he requires the assistance of his wise and holy adviser. The latter then takes up the cowries in one hand, and throws them on the leather—carefully noting how they fall. He repeats this action several times, rehearsing the principal symptoms of the case in question. When he has satisfied himself, he takes up his hooked stick; and, addressing himself to the suppliant, asks if the case is thus—proceeding to recapitulate the symptoms. By handing the suppliant the stick, he has put the latter on his honour to give a true and faithful account of the case. The clerical medicine-man then once more goes through the process of casting the cowrie shells, preparatory to the delivery of his final decision. Sometimes the suppliant is sent to another medicine-man, because the particular spirit who has wrought the mischief is one over which the first has no control. In the less difficult cases, the latter prescribes herbal remedies, to be applied either externally or internally.

In case of the mighty and wealthy members of his *clientele*, the sick person is first asked for a specimen of his saliva. This is received on a strip of plaintain leaf. Some animal—a fowl, a goat, or cow—is then forced to swallow it. The medicine-man then opens the body of the animal by a vertical incision, from the mouth to the stomach. The viscera are all carefully examined; every mark and spot is noted and counted. If the total number of these recorded is odd, the patient will recover; if even, he will die. The existence of but a single notable macula or pimple is of excellent augury: it presages long life and good health. A portion of the viscus, which is marked by a notable spot, is cut out, dried, stitched in a tiny leather bag, and worn by the person round the neck—as an amulet—to ward off physical evil for the remainder of life.

There is also a *water test*. The medicine-man brings a pot of water, into which the sick person is made to expectorate. Some dust formed of dried and powdered herbs is then thrown on the surface of the water, and the medicine man proceeds to roll the pot from side to side. If the floating layer of dust breaks up into an odd number of parts, the omen is favourable; if into an even number, the forecast is gloomy. When the prognosis has thus been given, the case is prescribed for. Herbs are very generally employed. Sometimes a special procedure to appease some spirit, or to secure the services of such agent, will be found necessary.

Throughout the various parts of the territory the local deities have huts for their residence; these also accommodate their officiating priests. Every native keeps one or more small huts near his house, where the spirits of his deceased relatives reside. If a suppliant is sent for aid to one of the gods, he must always bring an appropriate offering, according to his means. The wealthy man brings a cow; the less so, a goat, a fowl, a goat-skin, a feather—in descending scale. But no candidate can present himself without some bark-cloth and beer. A healing remedy of proportionate value is then prescribed. If the suppliant is sent to the hut of one of the spirits of his kindred, he kneels by the door and addresses the spirit inside; he recounts the troubles which brought him there; then promises a present proportioned to the rank of the spirit, and proceeds to implore its assistance in counteracting the influence of the hostile spirit who has effected the evil in question. He pours some beer on the doorstep and says: "I have stated my case. I will give you a present (here he mentions what he means to give); now let him who overcomes drink." The animal, a fowl dedicated to the deity, is turned loose by the hut, and is retained there as the property of the resident spirit. It is replaced in case of death. When the offering consists of skins or feathers they are tied to the door-post; if of a bark-cloth, it is placed within the hut. This latter is, however, carried off to clothe the sick person for a time, who thus receives the salutary influence of the spirit.

Sometimes it is found necessary, after failure of the efforts of the first medicine-man consulted, to have recourse to the good offices of a priest of a higher order. In such cases the special priest-medicine-man of the god has to consult the deity alone. He accordingly enters the hut and tells the divine tenant who the suppliant is, and what business has brought him. He does this by kneeling by the reed-wall which separates the spirit-room from the rest of the house, and speaking through this partition to the divine resident inside. At the conclusion of this preliminary performance, he goes out and brings in the suppliant; and they then kneel together before the wall, while the latter gives his own version of the trouble in question. When this has been done the priest takes a pipe of tobacco and "smokes it fiercely." This works him into a state of ecstasy, in which he loses his identity; he speaks in loud and excited tones, and these are easily recognised as the voice of the god speaking through the person of his agent. The deity, so incarnated, explains to the suppliant both the cause of the illness in question and the appropriate remedy. When this divine revelation has been completed, the medicine-priest retires to the rear of the hut; the deity then leaves him, he regains his individual personality, and may go about as before. The same priest of the deity may not always be eligible as the medium; a particular one has to be selected in some cases. In certain instances, a deity has but one priest to whom he reveals; the latter then always resides in the hut. But those special cases which require troublesome and complicated divine consultation usually occur only in female patients. In the case of males, it is generally sufficient for the priest-medicine-man to go in person to the patient's house after the preliminary investigation first described. When he arrives at the house of the sick man, the patient is carried out into the open; the medicine-man kills a cow or goat provided for the purpose, and catches the blood in a vessel. With some of this he sprinkles each door-post. He then takes a stout stick of three feet in length, fastens a bunch of grass to each end, places it across the door-way, and sprinkles it with the blood. The patient is then anointed with some of the blood —on the forehead, on either shoulder, and on either leg— just below the knee. He is then set on his feet, with a bark cloth around his shoulders; told to run as fast as he can, and jump over the stick in the door-way—allowing the bark cloth to fall off him as he does so—and make for his bed as fast as he can. During this performance he must by no means look round, but keep his eyes fixed on his bed—which he must make for as fast as possible.

Another method of treatment consists in taking the sick man into the garden, where the medicine man then cuts down a plantain tree. The trunk of the fallen tree is then slit, and the halves are separated widely enough to allow the sick man to pass between. It is then sprinkled with the blood of the sacrificed animal; the patient passes through, allowing his bark-cloth garment to drop off in doing so; and he makes for his bed, as before. The medicine-man then takes up the meat, the bark-cloth, and the cleft plantain stem, and goes in the opposite direction to that taken by the sick man. He throws the plantain on one of the main roads, and reserves the meat and the bark-cloth for his own private use. The very poor, who are unable even to supply even a fowl for the ceremony, are sprinkled on such occasions with a mixture of water and aloes.

A curious item of their clinical faith is, that the evil-disposed spirit which causes sickness without the special intervention of any living person, is usually believed to be the aunt of the patient—on the male side. Some of these are exceedingly malignant, and are causing continual sickness in the native home. In such cases the medicine-man is obliged to capture and destroy the spirit. This important operation he performs by bringing to the hut a cow or buffalo horn, into which he puts a cowrie or snail shell with a plantain seed. He attaches this to the end of a long stick, and passes it upwards along the central pole of the hut till it nearly reaches the roof. It is in this region that the spirit always resides. He then works the stick, with attached horn, about, till the contained shells and seed make a special squeaking noise; this is the *voice of the spirit*, which has got into the horn. The operator then rapidly lowers the latter, covers it with a piece of bark cloth, plunges it into a pot of water, and carries it off to the next river, where he submerges it. If a river is not available, he carries the pot, with its mouth well secured, to some unreclaimed grass land, where he leaves it to be destroyed by the next "prairie fire."

Baganda women are sometimes possessed by troublesome spirits; the principal symptoms are abdominal pains and swellings. The remedy is to have the patient inhale the smoke of certain herbs, burning upon hot embers. The smoke is, of course, of a quality which the spirit cannot tolerate. The latter accordingly flies to a less odoriferous locality. This, after all, displays a therapeutic cousinship to the burnt feathers and assafœtida treatment of "fits of the mother" in the Western regions of Europe.

Literature.

MOOR ON SUGGESTED STANDARDS OF PURITY FOR FOODS AND DRUGS. (a)

The desirability of adopting some more stringent and well-founded standards or limits of purity for drugs as well as for many food products, has occupied the attention of pharmacists and many others for some time past. Up to the present we are not aware of any work which deals in the manner of the present volume with the solution of this important problem.

The British Pharmacopœia and its commentaries, such as Squire's well-known "Companion to the British Pharmacopœia" and others, have in part succeeded in laying down more or less minute directions as to the preparation, dosage, and tests of purity of many of the more important drugs. The question as to which drugs should or should not be recognised officially the British Pharmacopœia has already prominently dealt with. But it is, we think, generally admitted that much yet remains to be done before we can claim to have anything like a perfect system of standards for drugs. To accomplish this satisfactorily requires the collaboration of those having special knowledge of both raw and manufactured drugs with analysts who have made these their special object of study.

It is to be feared that too often little attention is given by medical men to the actual potential strength of the preparations, be they food or drug which they prescribe; and frequently this is so because as yet, no satisfactory method of assay or standard of quality for the particular preparation exists. The importance of this and its bearing upon the interests of the general public is, doubtless, frequently best appreciated by medical men themselves.

Whilst, in the British Pharmacopœia we have, in most cases, very exact statements of the quantities of the various ingredients to be used in making certain preparations, and the total volume or weight of the resulting product; in the case of the raw drugs so employed it is often found that although very correct botanical description and other characters are stated, no allowance has been made for the variations in quality or content in active constituent which the latter, it would appear from the work before us, may and often do exhibit. A study of some of the results of analyses of commercial samples of drugs furnished by Mr. Moor in collaboration with several other workers in the present useful collection, makes it very clear that considerable variation is to be found in the composition of a large number of those drugs in common use, either in the amount of their most active constituent or in some other valuable quality. Such being the case, the need for more definite limitation as to their purity is, we think, obvious. To insist upon rigid standards in the case of some drugs is, we are aware, at present not practicable, owing mainly to the want of sufficient data upon which to go. This again is in part due, no doubt, to the fact that up to the present no satisfactory method for their assay is known. We believe, however, that the present very useful work will go far to remedy this state of things and towards making possible the adoption of many more correct and rational standards than at present exist.

Whilst, in the case of some of the drugs instanced, it would, we think, have been of advantage to have had further collateral data regarding them, with some information as to their origin, physical characters, &c., much credit is due to the author, Mr. C. G. Moor, for the vast amount of trustworthy data, largely representing his own personal work, which he has now brought together. We trust that the effort which he and his co-workers have made to deal with this important subject will receive the support and co-operation of others engaged in pharmaceutical research to whom the many references to other papers, &c., should be found most valuable.

This work is peculiarly well suited to the needs of town clerks, medical officers, and others who are called upon to decide whether in any particular case proceedings under the Foods and Drugs Acts ought to be instituted against vendors of foods and drugs; there is, in fact, no other work with which we are familiar giving such clear and accurate statements of the proper constitution of the various preparations of food and medicine. It is to be hoped, too, that an additional stimulus will be given to the makers of galenical preparations, wholesale druggists, and others to adopt, with the dawning progressive instincts of the present time, a more thoroughly systematic and scientific control over the raw and finished products which they turn out.

CANCER RESEARCH. (a)

Although Middlesex Hospital has since 1792 devoted particular attention to the care of patients the subject of malignant disease, it is only of recent years that the authorities seem to have been touched by that scientific spirit which is the characteristic of modern times, and which restlessly seeks to probe matters to the bottom. The awakened interest, both professional and popular, has at last aroused the "cancer charity of the Middlesex Hospital," to provide ways and means for a serious investigation of the problems which encircle the question of "cancer." This volume is the first record of the work accomplished under this new *régime*. We are given to understand that the original intention with regard to the issue of reports from the cancer research laboratories was that one volume should be published in connection with the completion of each series of 500 cases of malignant disease investigated. It is unfortunate that this excellent plan has been departed from so early, for the present volume is peculiarly silent as to details of the actual work accomplished in connection with the investigations of the cancer cases.

(a) "Suggested Standards of Purity for Foods and Drugs." By C. G. Moor, M.A., F.I.C., F.C.S. London: Baillière Tindall, and Cox. 1902. Price 7s. 6d.

(a) "Reports from the Cancer Research Laboratories: The Middlesex Hospital." Vol I. Edited for the Cancer Investigation Committee, by Alexander G. R. Foulerton, F.R.C.S. Pp. 204 with 8 plates. London: Macmillan and Co. 1902.

The chief feature of the volume is a most readable account by Dr. Sidney Coupland of the "cancer charity" connected with the hospital, and covers the period 1792 to 1902. Dr. W. P. Young furnishes an interesting study of the pathogenic action of blastomycetes; Dr. Cecil Price-Jones deals with the cytology of the blood in malignant disease; Mr. W. T. Hillier furnishes somewhat scanty statistics relating to 500 cases under treatment: and Dr. Foulerton and Dr. Cecil Price-Jones have a note on the bacteriological examination of cases of carcinoma and sarcoma.

As far as it goes the work is of value, but it does not appreciably advance our knowledge of the subjects treated.

HÆMOGLOBIN SCALE. (*a*)

Tallquist's "Hæmoglobin Scala" has gained considerable popularity in the land of its birth, and also in America, and Messrs. Down Brothers have been well advised in making it available for workers in this country.

It consists of a scale, marked so as to indicate the percentage amount of hæmoglobin in a sample of blood compared with it. Its ease of application should serve to make it useful for clinical purposes.

A large number of portions of absorbent paper, capable of being readily detached, are also provided. The drop of blood is allowed to soak into the absorbent paper, and as soon as the blood stain has lost its humid gloss it is pressed against a pad of filter paper and compared with the scale in good direct daylight. The *modus operandi* is thus of the simplest, and merely consists in the comparison of a spot of blood absorbed by the blotting-paper with the graduated scale of tints. The percentage, as already indicated, is marked against each shade of colour. The results are sufficiently accurate to afford a useful means of record in clinical work.

THE YELLOW FEVER EXPEDITION. (*b*)

The Liverpool School of Tropical Medicine, although young in years, has won a distinguished place among those institutions which have wrought strenuously and with well-directed energy for the up-building of the Empire and the welfare of the race. The present work is the seventh in a valuable series of memoirs dealing with the pathology of tropical diseases. There is a pathetic interest about the volume before us, for in the work of which it is the record Walter Myers laid down his life, a sacrifice to the study of the fell disease he was seeking to combat.

Dr. Durham has furnished us with a very complete and in many ways valuable account of the work of "the yellow fever expedition." Although the results can scarcely be held to be conclusive they go to show that in all probability yellow fever is due to a small and fine bacillus, and that mosquitos play a part in the transference of the disease.

The volume is a detailed record of much painstaking and dangerous work, and throws considerable light on a particularly perplexing and difficult subject.

NEW BOOKS AND NEW EDITIONS.

The following books have been received since the publication of our last monthly list:—

Baillière, Tindall and Cox (London, Dublin and Paris).

Manual of Surgery (University Series). By William Rose, M.B., F.R.C.S., Professor of Surgery in King's College, and Albert Carless, M.S., F.R.C.S. Fifth Edition, revised. Price 21s.

Suggested Standards of Purity for Food and Drugs. By C. G. Moor, M.A.Cantab., F.I.C. Pp. 258. Price 7s. 6d.

Text-Book of Diseases of the Ear and Adjacent Organs. By Adam Politzer, M.D., Docent Professor of Otology in the University of Vienna. Fourth Edition. Translated under the Author s supervision by Drs. Ballin and Heller. Pp. 824. Price 25s.

Le Sang, Physiologie Générale, par Marcel Labbé, M.D. Pp. 96. Price 1s. 6d.

Ambulance Organisation of an English Army Corps in the Field. By Major C. J. Addison. Second Edition. Pp. 16. Price 1s. net.

Charles Carrington (Paris).

The Plague of Lust. By Dr. Julius Rosenbaum. Two vols. Pp. 539 Price 42s.

Cassell and Co. (London).

A Manual of Medical Treatment or Clinical Therapeutics. New and revised Edition in two vols. Price 21s.

J. & A. Churchill (London).

Diet and Food. By Alexander Haig, M.A., M.D.Oxon., F.R.C.P. Fourth Edition. Pp. 127. Price 2s.

Heath's Practical Anatomy: a Manual of Dissections. Edited by J. Ernest Lane, F.R.C.S. Ninth Edition. Pp. 696. Price 12s. 6d.

Manual of Hygiene. By W. H. Hamer, M.A., M.D., &c. Pp. 622. With 93 Illustrations. Price 12s. 6d. net.

The Blood: How to Examine and Diagnose its Diseases. By Alfred C. Coles, M.D. Second Edition, with 6 coloured plates. Pp. 286. Price 10s. 6d.

Caries of the Spine. By Heather Bigg, F.R.C.S.Ed. Pp. 82. Price 2s. 6d.

A Treatise on Anatomy. By various authors. Edited by Henry Morris, M.A., M.B.Lond. Third Edition, revised. Pp. 328, with 846 illustrations, plain and coloured. Price 36s.

Wm. Clowes and Sons, Ltd. (London).

Transactions of the British Congress on Tuberculosis for the Prevention of Consumption. Vols. I., II., III., and IV. (Official).

Henry Kimpton (London).

The Science and Art of Prescribing. By E. H. Colbeck, B.A., M.D.Cantab., &c., and Arnold Chaplin, B.A., M.D.Cantab., &c. Pp. 185. Price 5s. net.

H. K. Lewis (London)

Ligaments: their Nature and Morphology. By J. Bland-Sutton. Third Edition. Pp. 112 Price 4s. 6d.

The Etiology of Typhoid Fever and its Prevention. By W. H. Corfield, M.D.Oxon., F.R.C.P. (Milroy Lectures.) Pp. 175. Price 2s. 6d.

Hygiene and Public Health. By Louis Parkes, M.D., D.P.H. and Kenry Henwood, M.B., D.P.H. Second Edition. Pp. 775. Price 12s.

J. B. Lippincott and Co. (Philadelphia and London).

International Clinics. Vol. II. Edited by Hy. W. Cattell, A.M. M.D., Philadelphia. Pp. 295.

Longmans, Green and Co. (London).

Elementary Biology. Descriptive and Experimental. By John Thornton, M.A. Pp. 270. Price 3s. 6d.

The Practitioner's Guide. By Walter Carr, M.D., F.R.C.P., T. Pickering Pick, F.R.C.S., Alban H. G. Doran, F.R.C.S., and Andrew Duncan, M.D., F.R.C.S., M.R.C.P. Pp. 1,107. Price 21s.

Macmillan and Co., Limited (London).

A Manual of Medicine. Edited by W. H. Allchin, M.D.Lond., F.R.C.S. Vol. IV.: Diseases of the Respiratory and Circulatory Systems. Pp. 493. Price 7s 6d.

New Sydenham Society. (Agent: H. K. Lewis, London.)

An Atlas of Illustrations of Clinical Medicine, Surgery, and Pathology. Compiled for the New Sydenham Society. (A Continuation of the "Atlas of Pathology.") Fasciculus XIV. (Double Number). Fasciculi I. and II. of New Series. Frambœsial Syphilis (Yaws and Parangi). With Descriptions by Jonathan Hutchinson, F.R.C.S., F.R.S., LL.D. and Sir William Kynsey, C.M.G., F.R.C.P.I. Plates A to H and LXXV.—XCI. Price to Non-members, £1 1s.

Rebman, Ltd.) London).

The Treatment of Tabetic Ataxia by Means of Systematic Exercise. By Dr. H. S. Frenhel. Pp. 185, with 132 illustrations. Price 12s. 6d. net.

Tuberculosis: as a Disease of the Masses, and how to Combat It. Prize Essay by S. A. Knopf, M.D. Pp. 76. Price 1s. net.

W. B. Saunders and Co. (Philadelphia and London).

Treatise on Diseases of the Skin. By Henry W. Stelwagon M.D., Ph.D. With 230 illustrations in the text, and 26 full-page plates. Pp. 1,115. Price 25s.

Atlas and Epitome of Abdominal Hernias. By Dr. George Sultan. Translated from the German. Edited by William B. Coley, M.D. Pp. 277. With 112 illustrations. Price 13s. net.

Mr. Joseph Whittaker, M R.C.S., of Salford, was the victim of a nasty fall about three weeks since, which resulted in injury to his arm and leg. He died somewhat suddenly last week. At the inquest it transpired that Mr. Whittaker was suffering from diabetes, and that the fall was due to his slipping over a badly-laid flagstone. A verdict was returned of "Death from diabetic coma, accelerated by the accident."

(*a*) "Hæmoglobin Scala." By T. W. Tallquist. Helsingfors: Wentzel Hagelstam's Förlag. English Agents: Down Brothers, 21, St. Thomas's Street London, S.E. Price 4s. 6d.

(*b*) "Report of the Yellow Fever Expedition to Para of the Liverpool School of Tropical Medicine and Medical Parasitology." By H. E. Durham. Pp. 79 with Illustrations and Plate. Published for the University Press of Liverpool by Longmans, Green and Co. 1902. Price 7s. 6d.

Medical News.

The Results of Vaccination in Porto Rico

The remarkable statistics relating to small-pox and vaccination in Porto Rico, which were brought to the notice of the American Association of Military Surgeons at Washington by Brigade-Surgeon Ames, furnish reading which will, we fear, prove unpleasant to the community of anti-vaccinationists. Briefly summarised, these statistics are as follows:—In October, 1898, small-pox was endemic in the island, in December it was epidemic, in January, 1899, it had "honeycombed" the island, in February there were over 3,000 recent cases, and the disease was rapidly spreading. During the last-mentioned month, systematic compulsory vaccination was adopted in all parts of the island, and by July 1st of the same year 860.000 vaccinations had been made in a population of 960,000. Of these 87·5 per cent. were successful. In the two and a half years which elapsed between that date and the writing of Brigade-Surgeon Ames' article the mortality from small-pox averaged two per annum, instead of the former average annual mortality of 621. "Can any *honest*, intelligent person doubt in face of these indisputable and easily verified facts what it was that in four short months drove small-pox from its wide and long-time reign on the island, and has since kept it out?" asks the writer of the article from which we quote. It will be interesting to know how the community to which we have alluded will answer this question, as it seems to us that unless they can state that the cause was not vaccination, the reason for their existence is gone. The anti-vaccinationist will however, doubtless at once see that Brigade-Surgeon Ames' question was not asked of him.

King's College (University of London).

The following scholarships and exhibitions have been awarded:—Clothworkers' Science Exhibition—A. G. Le Clercq, £40; S. Summerson, £30; W. T. Wheeler, £30. Sambrooke Medical Scholarships—H. L Gauntlett, £60; R. C. Paris, £40. Warneford Entrance Medical Scholarship—E. G. Gauntlett, £75. Engineering Entrance Exhibitions—A. P. Chalkley, £15; A. E. O'Dell, £15; F. C. Summerson, £10. Sambrooke Exhibition (Classics)—E. L. Wells (£50).

Death from a Fractured Skull.

Mr. Alfred Edward Odling, M.R.C.S., of East Lincolnshire, fractured his skull last week as the result of falling down the stairs at the Windmill Hotel at Alford, and he died two days later. At the inquest a verdict of accidental death was returned.

Death under Chloroform at Guy's.

An inquest was held at Guy's Hospital last week on the body of a man, aged 39, to whom chloroform was administered for the purpose of an operation for the relief of a tumour pressing on the trachea. Only one drachm of the anæsthetic had been administered. The chloroform was administered by the assistant house surgeon, Mr. Claude Tessier, who stated that he had given the drug in upwards of two hundred cases without a death. The percentage of deaths under chloroform was stated to be one in a thousand, which is vastly more than that usually retailed to the jury by coroners in such cases. The usual verdict was returned.—A similar mishap is reported from South Shields, where the managing director of a local theatre died under chloroform before the operation was even begun.

The Small-pox in Barbados.

Reuter's correspondent at Barbados reports that the spread of small-pox continues, notwithstanding the steps taken to check it. The Governor appointed public vaccinators, and free vaccination was given to the people. The latest returns handed in to the Quarantine Board show that some 20,000 persons have been vaccinated since the outbreak of small-pox. Every steamer brings a fresh supply of lymph, and it is hoped that with energetic vaccination the disease will be at least confined to the localities where it at present exists. The total number of cases up to Sept. 24th was 772, of which 103 have been discharged as cured, 27 have proved fatal, and 642 cases remain under treatment, including 26 patients taken into the hospitals that day.

University of Glasgow.

The following have passed the first professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (B., Botany; Z., Zoology; P., Physics; C., Chemistry):—

Wallace Wright Adamson (B., P.), Archibald Aitchison (B., P.), William Allan (B., Z.), Thomas M'Call Anderson (B., P.), John Atkinson (B., P.), Herbert Bertram (B., P.), Donald Price Bremner (B., C.), James Nimmo Brown, M.A. (B., P.), John Cameron (B.), William Rome Cammock (Z., C.), George Campbell (B., Z., P., C.), William Archibald Campbell (B., P.), John Paterson Carmichael (P.), Matthew Ignatius Thornton Cassidy (B., P.), Henry Howard Christie (B., P.), Alexander Beck Cluckie (B.), James Coutts (B, Z, P., C.), Thomas Lawson Craig (B., P.), Neilson Davie (B., P.), Alexander Dick (Z., P.), James Cowie Dick (Z., P.), John Alexander Doctor (B.), Robert Donald (P., C.), James Richan Drever, M.A. (B, C.), Richard John Driscoll (P.), James Dunbar (Z.), Alexander Wylie Eadie (B., P.), Ernest Milne Eaton (B., P), William Miller Fairlie (B., P.), Thomas Loudon Fleming (P., C.), George Fletcher (B, P.), George Muir Fraser (B., P.), James Wilfred Georgeson (C.), William Gilfillan (B., Z., P.), Robert Govan (B., P.), John Vincent Grant (P.), Thomas Purdie Grant (B., P.), Arnold Harris Gray (C.), James Dow Gray (B., P.), David Hamilton (B., P.), William Towers Hardie (B., C.), James Duncan Hart (B, P.), James Dunlop Kidd (C.), James Towers Kirkland (C.), George Ligertwood (P., C.), Angus Macaulay (P.), John M'Cartney (C.), James M'Donald (B), James M'Farlane (B., P.), Robert M'Inroy (Z., P., C.), John Henry M'Kay (B., P.), William Anderson M'Kellar (B., P.), Murdo Duncan MacKenzie (B., Z, P., C.), Thomas Cooper Mackenzie (B, P.), Alister Argyle Campbell M'Neill (B., P.), Charles James Colquhoun Macquarie (B., P.), Isa Carswell Marshall (B., P.), William Matheson (B., Z., P., C.), Robert May (B.), John Clark Middleton (B., P.), Allan Frederick Miller (B., Z., P.), John Wilson Miller (B.), William Miller (C.), Peter Mitchell, M.A. (C.), Robert Wright Mitchell (C.), Hugh Walker Moir (Z.), Hugh Morton (B), Patrick O'Brien (B., P.), Patrick Joseph O'Hare (C.), John Oswald (B.), James Hogg Paul (B., P.) Frederick Gordon Robertson (B., P.), James Henry Anderson Robertson (C.), Murdoch Mann Rodger (Z., P.), William James Rutherfurd (B.), William Wilkie Scott (B., Z.), John Sharp (B), Robert Wilfrid Simpson (C.), Alexander Hunter Sinclair (B., C.), William Smellie (B., Z., P., C.), James Anstruther Smith (B.), John Steedman, (B., P.), John Stevenson (B., P.), William Stevenson (Z.) John Stewart (B., P.), John Torrance Weir Stewart (P.), Matthew John Stewart, B, P.), John Anderson Struthers (B., P.), David Laurence Alexander Tate (P., C.), Robert Scott Taylor (B., P.), Robert Todd (Z.), Martin Turnbull (Z., C.), John Morris Walker, (B., P.), Hugh Watson (B., Z.), John Weir (B., P.), James Kennedy Welsh (B., P.), David John Williams (P., C.), George Haswell Wilson (B., P.), Samuel Wilson, M.A. (B., P.), William Mitchell Turner Wilson (Z), Moses Youdelevitz (B., Z., P., C.) Women—Jeannie Montgomery Andrew (B., Z), Martha Maclean Buchan (B., Z.), Agnes Picken (B., Z.), Jeanie Hinshaw Stewart (B., Z.).

The following have passed the second professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (A., Anatomy; P., Physiology; M., Materia Medica and Therapeutics):—

Andrew Blair Aitken (A., P., M.), William Smith Allan (P.), Andrew Woodroffe Anderson (P., M.), Henry Graeme Anderson (M.), John Bain (P., M.), Allan Robertson Barrowman (M.), Robert Daniels Bell, M.A. (M.); George Thomson Bogle (P.), Thomas Brodie (A.), Charles Brown (A), Thomas Murdoch Campbell, M.A. (P., M.), Robert Buchanan Carslaw, M.A. (M.), Thomas Goodall Copestake (M.), Charles Milligan Drew, M.A. (P.), Hugh Harvey Fulton (M.), William Harold

Gillatt (M.), William Macmillan Gilmour (A.), David Livingstone Graham (M.), John Graham (M.), George Munn Gray (M.), Louis Leisler Greig (M.), Saul Hyman Harris (P.), Alexander Robertson Forrest Hay (M.), James Waugh Hay (P.), John Cochrane Henderson (M.), Ralph Vincent Howell (P.), Alexander Hunter (P., M.), Archibald Yuill Hutchinson (A., P., M.), James Rutherford Kerr (A., P.), John Kerr (A.), William Jamieson Logie (M.), Peter Lowe, M.A., B.Sc. (P., M.): Thomas Symington Macaulay (M.), John Duncan M'Callum, M.A. (A., P., M.), Donald Carmichael M'Cormick (M.), Neil M'Dougall (A., P., M.), James Boston M'Ewan (M.), Tom Duncan M'Ewan (M.), Duncan Macfadyen (M.), John M'Farlane (M.), Robert Macfarlane (M.), James Denniston Macfie (P., M.), Alexander Stuart Murray Macgregor (A., P., M.), James M'Houl (M.), Charles Gordon Mackay (A., P., M.), David James M'Leish, M.A. (M.), Matthew Thompson Drummond M'Murrich (P., M.), Andrew Brown M'Pherson (A.), Richard Cameron Macpherson (P., M.), James Marshall, P., M.), William Blair Morton Martin (A., P.), John Moffatt (P., M.), John Muir (M.), Macdonald Munro (M.), John Murdoch, A., P., M.), Frank Anderson Murray (A., P.), George Clement Nielson (M.), Thomas Orr (A.), Howard Henderson Patrick (M.). John Pearson (A., P., M.), John Clegg Pickup (M.), Andrew Maclean Pollock (M.), James Porter (M.), William Murdoch Rae (P.), James Watson Richmond (P., M.), Berkeley Hope Robertson, M A. (M.), Robert Thin Craig Bobertson (A.), John Macdonald Ross (A., P.), William Hermann Sieger (P., M.). Robert Alexander Slater (P., M.), George Goldie Smith, B.Sc. (M.), Morrison Wood Smith (P., M.), William Robb Taylor (P.), William Templeton (M.), James White Thomson (M.), William Young Turner, M.A. (A., P, M.), Thomas Macknight Watt (M.), David Watson Wilson (A., P., M.), George Wilson (A.).

Women.—Bethia Shanks Alexander (P., M.), Annie Agnes Baird, M.A, (P.), Mary Theresa Gallagher (M), Jane Hamilton M'Ilroy, M.A., B.Sc. (M.), Florence Mann (M.), Margaret Walker Millar (P.), Harriet Rowland Louise Reid (P.), Jane Reid Shaw (M.), Lily Smellie (M.), Annie May Yates (M.).

The following have passed the third professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (P., Pathology; M., Medical Jurisprudence and Public Health):—

John William Arthur (P.), Thomas Ballantyne (P.), Andrew Farm Bell (P.), Thomas Bennett, M.A. (P.), William Thomas Bolton (P., M.), Robert George Bradford (P., M.), John Brown (P., M.), Carl Hamilton Browning (P., M.), Robert Bruce (P.), Daniel Lyall Carmichael (P.). Alexander Erskine Clark (P.), John Cross (P., M.), James Forsyth, (P., M.), James Glover (P., M.), William Harvey (M.), John Monnette Huey (P., M.), Alexander Jamieson (M.), Alexander Dingwall Kennedy (P.), Thomas Lovett (P., M.), Donald Macaulay (M.), John Finlay Macdonald (P., M.), Alexander Stewart M'Millan (P, M.), Andrew Alexander M'Whan (P., M.), John Baird Morton (P., M.), Alexander Harper Napier (P., M.), James Carmichael Pairman, M.A. (P., M.), David Penman (P.). George Richmond (P., M.), Peter Hamilton Robertson (M.), Lawrence Drew Shaw (P., M.), John Black Stevenson (M.), William Davidson Henderson Stevenson, M.A. (M.), John Allan Thom (P., M.), John Turnbull (M.), Joseph Walker, M.A. (M.), Robert Wallace (P., M.), Robert Watson (M.), Robert Tait Wells, M.A. (M.), George Henry Wildish (P., M), Hugh Young (P., M.), John Young (Glasgow) (P., M.), Watson Young (M.).

Women.—Jeanie Auld (P., M.), Agnes Wallace Cameron (P., M.), Jessie Galloway Duncan (P.), Jane Reid Foulds Gilmour (P., M.), Margaret Hardy (P., M.), Alice Wesley Maclean (P., M.), Martha Hunter Scott (P., M.), Janet Gardner Waddell (P., M.).

At the recent professional examinations for the Degrees of M.B., Ch.B., the following candidates passed with distinction in the subjects indicated:—

First examination—In Botany and Physics: John Stevenson, Matthew John Stewart. In Zoology and Physics: William Gilfillan. In Physics and Chemistry: Robert Donald. In Botany: Patrick O'Brien, John Steedman, Samuel Wilson, M.A. In Zoology: William Rome Cammock. In Physics: William Archibald Campbell, Matthew Ignatius Thornton Cassidy, Henry Howard Christie, Neilson Davie, Ernest Milne Eaton, George Fletcher, John Clark Middleton, Frederick Gordon Robertson, Robert Scott Taylor, John Morris Walker, John Weir, James Kennedy Welsh, George Haswell Wilson. In Chemistry: William Miller, Peter Mitchell, M.A.

Second Examination—In Anatomy, Physiology, and Materia Medica and Therapeutics: Andrew Blair Aitken. In Anatomy and Physiology: William Blair Morton Martin. In Anatomy: John Duncan M'Callum, M.A. In Physiology: Alexander Stuart Murray Macgregor. In Materia Medica and Therapeutics: Allan Robertson Barrowman, Robert Daniels Bell, M.A., Robert Buchanan Carslaw, M.A., George Munn Gray.

Third Examination—In Pathology and Medical Jurisprudence and Public Health: James Glover. In Pathology: Carl Hamilton Browning, John Baird Morton, Martha Hunter Scott.

The Royal University of Ireland.

The Examiners have recommended that the undermentioned candidates be adjudged to have passed the first examination in Medicine, Autumn, 1902:—J. A. Black, J. B. Butler, Gault Calwell, J. M. A. Costello, R. Cox, N. M. Donnelly, J. Dooley, P. Ferris, J. J. Flood, Jane McC. Fulton, W. S. Graham, C. E. L. Harding, C. R. Harvey, W. T. Henderson, J. J. Hickey, J. Kilgarriff, V. J. McAllister, P. T. McArdle, R. A. M. L. McCrea, J. J. O'Neill, W. Riddell, Maria Rowan, S. J. Watson.

The undermentioned candidates have qualified upon their answering for further examination for Honours in the subjects set after their names (B., Botany, C., Chemistry, P., Physics, Z., Zoology):—J. A. Black (Z., C., P.), J. B. Butler (B., Z., C, P.), Gault Calwell (C.), R. Cox (P.), N. M. Donnelly (Z., P.), C. E L. Harding (C.), C. R. Harvey (B., Z., C., P.), J. Kilgarriff (Z.), V. J. M'Allister (B., Z.), W. Riddell (P), Maria Rowan (B., P.)

University of Durham.

At the Convocation holden on Saturday, September 27th, 1902, the following degrees were conferred, viz.:—

Doctor in Medicine:—Christopher O. Bodman, M.B., B.S., Durh.; Philip Boobbyer, M.B., M.S., Durh.; Sidney H. Hawley, M.B., Durh.; Henry Smurthwaite, M.B., B.S., Durh.; Harold Robert D. Spitta, M.B., B.S., Durh.; Joseph B. Stephenson, M.B., B.S., Durh.; Sydney D. Turner, M.B., B.S., Durh.; John C. Velenski, M.B., B.S., Durh.

Doctor in Medicine for Practitioners of Fifteen Years' Standing:—George A. Edsell, M.R.C.S., L.R.C.P., L.S.A.; Ernest H. Ellison, M.A., M.R.C.S., L R.C.P., L.S.A.; George W. H. French, F.R.C.S.; John H. Gough, M.R.C.S., L.R.C P, F.R.C.S. E.; George F. A. Harris, M.R.C.S., M.R.C.P.; Hillyard W. Haydon, M R.C.S., L.R.C.P., L.S.A.; John Jones, M.R.C S., L.R C.P., L.S.A.; John E. London, M.R.C.S., L.R.C.P., L.S.A.: Alfred E. W. Ramsbottom, L.R.C.S.I., L.M.; William L. Symes, L.R.C.S., F.R.C.P. I., L.M.; Onslow A. Wickham, M.R.C.S., L.R.C.P., L.S.A.; Lionel H. Williams, M.R.C.S., L.S.A.

Bachelor in Medicine (M.B.):—Reginald Bigg, M.R.C.S., L.R.C.P., Anthony B. Bradford, Annie T. Brunyate, John Cooper, B.Sc., Ida Emilie Fox, James W. Gibson, George Mack, Leonard C. Newton, Monica L. Robertson, Thomas C. Rutherfoord, M.R C.S., L.R.C.P., Gayton W. Smith, M.R.C.S., L.R.C.P., Basil E. Spurgin, Charles R. Stewart, James B. Waters, Frederick G. Wilson, Robert Younger.

Bachelor in Surgery (B.S.):—Reginald Bigg, M.R.C S, L.R.C.P., Anthony B. Bradford, Annie T. Brunyate, John Cooper, B.Sc., Ida Emilie Fox, James W. Gibson, George Mack, Leonard C. Newton, Monica, L. M. Robertson, Thomas C. Rutherford, M.R.C.S., L.R.C.P., Gayton W. Smith, M.R.C.S., L.R.C.P., Basil E. Spurgin, Charles R. Stewart, James B. Waters, Frederick G. Wilson, Robert Younger.

Bachelor in Hygiene (B.Hy.):—Emmeline Da Cunha, L.M. and S. Degrees, Esther M. Stuart, M.B., C.M.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Original Articles or Letters intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Dr. Raymond Davis is thanked for his communication.

Memo.—We fail to see that any advantage would accrue from a detailed discussion of the circumstances under which the unfortunate victim met with his death. We cannot at this stage go behind the verdict of the coroner's jury, which exonerated everybody concerned.

THE "FREEDOM" OF THE SOCIETY OF APOTHECARIES.

The Freedom of this Society carries with it, we believe, the Freedom of the City of London. In our advertising columns it will be seen that the Court propose this year to admit a number of Licentiates (not exceeding ten) to this privilege on payment of a fee of £28.

Ex-Forester.—Your explanation is a reason without being an excuse. We must decline any further correspondence on the subject.

A RECALCITRANT SUBJECT.

A well-known surgeon was imparting some clinical instruction to half-a-dozen students who accompanied him in his rounds. Pausing at the bedside of a doubtful case, he said, "Now, gentlemen, do you think this is, or is not, a case for operation?" One by one the students made their diagnosis, and all of them answered in the negative. "Well, gentlemen, you are all wrong," said the wielder of the free and flashing scalpel, "and I shall operate to-morrow." "No you won't," said the patient, as he rose in his bed. "Six to one is a good majority; gimme my clothes."

Treasurer.—The best plan is to pay the money into your bank in a separate account with an appropriate heading. This account might be arranged so that cheques thereon must be signed by your colleague as well as by yourself.

THE CASE OF DR. RAINSBURY.

To the Editor of The Medical Press and Circular.

Sir,—Referring to the appeal made by Dr. Rainsbury in discharging the judgment debt and costs in the above matter, I beg to enclose a further list of contributions; and on behalf of Dr. Rainsbury and the Council of the Midland Medical Union to thank those who have so generously responded to the appeal. I would add that there still remains a balance of £118 18s. 11d., towards which it is hoped that further contributions will be made.

I am, Sir, yours truly,
George S. O'Rorke, M.A.,
Secretary, Midland Medical Union.

Meetings of the Societies, &c.

Wednesday, October 15th.

Royal Microscopical Society (20, Hanover Square, W.).—8 p.m. Prof. Rev. T. G. Bonney: Demonstration on Rock Changes in Nature's Laboratory.

Thursday, October 16th.

Ophthalmological Society of the United Kingdom.—4.30 p.m. Mr. H. C. Baldwin: Dislocation of Eyeball through Palpebral Aperture, Reduction, Recovery.—Mr. E. Nettleship: (1) Birth Palsy of Sixth and Seventh Nerves on the Same Side; (2) Recovery of Perfect Vision in a Case of Family Optic Neuritis (Leber's Disease).—Mr. H. A. Lediard: Dermoid Cyst of Orbit causing Complete Dislocation of Eyeball.

Harveian Society of London (Stafford Rooms, Titchborne Street, Edgware Road, W.).—Clinical Evening. Cases will be shown by Dr. L. Guthrie, Dr. A. Morison, Mr. Watson Cheyne, Mr. E. Roughton, Mr. R. Johnson, Mr. F. Jaffrey, and others.

Friday, October 17th.

The Society for the Study of Disease in Children (11, Chandos Street, W.),—5.30 p.m. Clinical cases by Dr. W. Milner Burgess, Dr. Frank Deas, &c.

Monday, October 27th.

Odontological Society of Great Britain (20, Hanover Square W.).—Communication by Dr. J. W. Pare, and a Short Paper by Dr. Beddard and Dr. Spriggs, on Some Methods of Preparing Teeth for Histological Examination.

Appointments.

Beatty, J., M.D.Dubl., Medical Officer of Health for the Borough of Northampton.

Briggs, Walter, M.B., Ch.B.Vict., Junior House Surgeon to the Blackburn and East Lancashire Infirmary.

Brodrick, C. C., L.R.C.P., L.R.C.S.Edin., Medical Officer of Health to the Tavistock Rural District Council.

Brown, G. A., M.R.C.S., L.S.A., Medical Officer of Health to the Tredegar Urban District Council.

Bull, H. A., M.R.C.S., L.R.C.P., Medical Officer for the Colwick Division of the Stafford Union.

Flack, Frederick H., M.B., Ch.B.Vict., Senior House Surgeon to the Blackburn and East Lancashire Infirmary.

Forman, B. G., M.B., B.S.Edin., District Medical Officer for the Union of Scarborough.

Fullerton, Andrew, M.D., B.Ch., F.R.C.S.Irel., Honorary Assistant Surgeon to Royal Victoria Hospital, Belfast.

Harnett, Charles John, M.D.Lond., M.R.C.S., L.R.C.P.Lond., Surgeon and Agent to the Admiralty at Margate.

Hill, Abraham J., M.D.Lond., M.R.C.P., Honorary Physician to the Royal Infirmary, Liverpool.

Lyth, H. A., M.R.C.S., L.R.C.P., Assistant House Surgeon to the Rotherham Hospital and Dispensary.

Okell, George, jun., L.R.C.P.Irel., Certifying Surgeon under the Factory Act for the Winsford District of the County of Chester.

Potts, Lawrence, M.R.C.S., L.S.A., Medical Officer to the School for the Blind, Leatherhead.

Vacancies.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Pathologist and Registrar. An honorarium of £100 is attached to the post. Applications to Thomas Hayes, Secretary.

Grove Hall Asylum, Bow, London, E.—Assistant Medical Officer (male). Salary £150 a year, with board, furnished apartments, attendance and washing. Applications, personally if possible, to the Medical Superintendent.

Jenner Institute of Preventive Medicine.—Assistant Bacteriologist. Salary £200 per annum, with furnished rooms. Applications to the Secretary, Jenner Institute, Chelsea Gardens, S.W.

Lancaster County Lunatic Asylum.—Assistant Medical Officer. Salary £150 per annum, with board, &c. Applications to the Medical Superintendent.

Manchester Children's Hospital.—Lady Superintendent. Salary £100 per annum, with board, rooms, washing, and attendance. Applications to Secretary, Children's Dispensary.

Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Resident Medical Officer. Salary £100 per annum, with board, apartments, washing, and railway contract to Manchester. Applications to C. W. Hunt, Secretary.

Metropolitan Asylums Board.—Male Assistant Medical Officer for duty at the Asylum at Darenth, Dartford, Kent. Salary £150 per annum, with rations, lodging, attendance, and washing. Applications to Office of the Board, Embankment, E.C.

Monmouthshire Asylum, Abergavenny.—Junior Assistant Medical Officer (Male). Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

The Royal Infirmary, Sheffield.—House Surgeon. Salary £120 per annum, with board, lodging, and washing. Applications to George Henry Day, Secretary.

Wolverhampton and Staffordshire General Hospital.—House Physician. Salary £100 per annum, with board and lodging. Applications to Edmund Foster, House Governor and Secretary.

Woodilee Asylum, Lenzie.—Assistant Medical Officer. Salary £125 per annum, with board, lodging, and washing. Applications to Dr. Marr, Medical Superintendent.

Births.

Hancock.—On Oct. 10th, at Devonshire House, Gravesend, the wife of George C. Hancock, M.R.C.S., L.R.C.P., D.P.H.Lond., née Lenchars, of a daughter.

Melville.—On Oct. 9th, at Moville, Coonoor, Southern India, the wife of Major C. H. Melville, R.A.M.C., of a daughter.

Poole.—On Oct. 9th, at Hemplow, South Teddington, Hampton Wick, the wife of J. Copeland Poole, M.R.C.S., L.R.C.P., of a son.

Marriages.

Mackintosh—Parker.—On Oct. 8th, at St. George's Church, Dublin, Dr. M. Lovell Mackintosh, of Crowborough, Sussex, elder son of the late Dr. Mackintosh, of Crowborough, to Martha Donaldson, eldest daughter of J. D. Parker, Esq., of Castleconner, co. Kilkenny.

Sikes—Somerville.—On Oct. 4th, at Christiania, Alfred Walter Sikes, M.D.Lond., F.R.C.S., of 40, Argyll Road, W., second son of Richd. Cherry Sikes, Esq., Cork, to Mary Maitland, eldest daughter of Thos. Townshend Somerville, Esq., of Christiania.

Death.

Whiting.—On Oct. 3, at her residence, 47, Carson Road, West Dulwich, Surrey, Eliza Catherine Whiting, relict of the late James D. C. Whiting, M.R.C.S.Eng.

Original Communications.

UTERUS BICORNIS WITH RIGHT RUDIMENTARY HORN,

PERIODICAL DISTENSION OF THE RIGHT HORN WITH FLUID AND CONSEQUENT INFLAMMATION IN IT AND AROUND IT.—LATE MENSTRUAL PAIN.—OPERATION.—RECOVERY. (*a*)

By JOHN W. TAYLOR, M.Sc., F.R.C.S.,
Professor of Gynæcology, Birmingham University.

MISS M. B., æt. 17, was sent to me on October 28th, 1901, by Dr. Neal, of the Coventry Road, with the following note:—"I should be much obliged if you would give me your opinion concerning Miss B., and any hints for treatment. She has *very* severe pains after menstruation."

The patient was a well-developed, healthy-looking girl, complaining of very definite pain in the right side, which always came on about the fifth day after the onset of menstruation and lasted for a few days afterwards. This pain had been felt for nearly four years (from the date of the first menstruation), but had been latterly increasing in severity and becoming unbearable. The first menstruation occurred at thirteen years of age—since that time the patient had always been "regular." The period usually lasted four days. The discharge was slight in amount.

The following note was made of the examination:—"I find a large, hard tumour (presumably the right ovary) fixed to the right of the retroflexed fundus." "When I gently try if the uterus is replacable, this does not follow."

I came to the conclusion that both uterus and tumour were adherent in the pouch of Douglas; that the tumour was the cause of the right side pain, and that in all probability abdominal section would be necessary in order to deal with the condition.

Being loth, however, to submit so young a patient to operation unless absolutely necessary, I asked Dr. Neal to let me watch the patient for some weeks before deciding.

During this time the right-sided tumour very markedly decreased in size, showing that it was liable to considerable alteration in this respect. There was, however, no difference in the fixation of the pelvic contents, and but very little (if any) improvement in the pain after menstruation. As far as could be ascertained there was no tuberculous history, either in the patient or her family, and no history or danger of gonorrhœal infection.

On January 28th, 1902, exactly three months after the first consultation, I operated. I found a small muscular solid tumour, very adherent in the pelvic floor, to the right of the retroflexed and adherent uterus. Detaching this and the uterus from their adhesions I was able to bring the fundus forward and draw the tumour up to the incision for examination. It was then seen that the ovary was perfectly normal and with the tube was situated altogether on the outer side of the tumour. The question then arose whether this tumour could be a large myoma of the tube close to its uterine attachment, or a rudimentary horn. No trace of the round ligament could be found on the "uterine" side of the tumour, but beyond it, on the outer side, in close relation with the tube a ligamentary ridge was found curving forwards, which evidently represented the round ligament. The tumour was therefore decided to be formed by a right rudimentary horn. It is worthy of note, however, that in this case the uterus of the opposite (or left) side did not appear to suffer materially in size or shape by its separation. Except for the absence of the round ligament one would have said that its general appearance was that of a normal virginal uterus.

I removed the tumour of the right horn by a chain of ligatures without disturbing the other organs, so that nothing beyond it was taken away. The stump appeared to be solely one of muscle tissue, and no mucous canal was seen leading into or out of the tumour. On cutting into the tumour some dirty-looking watery fluid escaped from an apparently closed cavity in its centre lined with mucous membrane. There was no trace of blood within this cavity, which on the expulsion of the fluid immediately contracted.

At the close of the operation the pelvis was found to be perfectly clean, and the chain of ligatures held the uterus in "normal" anteversion.

The patient made a very easy and uneventful recovery. Her bowels were well opened on the following morning, and on February 12th she was discharged as convalescent. She attended to report herself on March 17th. She had passed her first menstrual period without pain, and was in good health and condition. Again on October 6th she attended at the out-patient department and reported that she had menstruated regularly without the slightest pain ever since the operation, and was perfectly well. The uterine horn removed was examined by Professor Leith, whose report is as follows:

Four pieces were selected and examined.

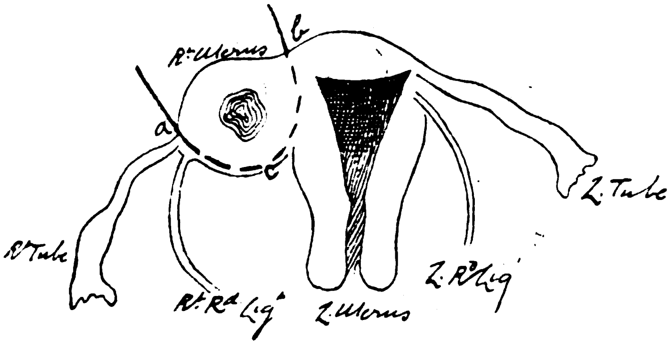
Piece I.—Taken from centre of body of (secondary) uterus. This shows a central cavity, lined by endometrium, with typical mucous membrane lining. It is surrounded by tissue, which is noticeably mapped out into definite muscular areas by bands of fibrous tissue.

Piece II.—Taken from tubal end (*a*) of semicircular incision line which ran from the Fallopian tube on the outer side to the uterine attachment on the inner side. This showed no sign of any cavity

---

(*a*) Read before the British Gynæcological Society on October th, 1902.

merely a solid muscular tissue mapped out into areas as above. The blood vessels were well formed and numerous.



DIAGRAMMATIC REPRESENTATION OF CONDITION.

Piece III.—Taken from uterine end of the same incision *b*). This showed no sign of any cavity leading from mucous cavity of horn into structure representing other uterus. It showed merely muscular tissue as above, with many fibrous bands and areas in it.

Piece IV.—Taken from between the other two (*c*) showed the same characters as the other two, with relatively less muscular and more fibrous tissue.

Remarks.—The interest of this case appears to me to lie, not only in its rarity and in the peculiar isolation of the mucous cavity of the rudimentary horn, but also in the explanation which the condition affords of the peculiar symptoms of the patient. The patient's pain was a definite, right-sided pain, attaining its maximum on the fifth day after the onset of menstruation. I thought at the time of her first visit that this was an extraordinary symptom to be associated with ovarian tumour, or enlargement, any ovarian pain usually preceding the menstrual flow, but no other explanation of the adherent tumour to the right of the fundus suggested itself to my mind.

While watching the case it was noticed that the tumour was subject to slow alteration in size, and the time of greatest enlargement appeared to correspond with that of greatest pain.

Viewed in the light of post-operative knowledge the explanation of these symptoms appears to be that at every menstrual period some exudation occurred into the little closed mucous chamber of the horn, that the distension of this attained its maximum about the fifth day after the onset of the period, and that it then slowly subsided. This process must itself have been painful and must have caused some inflammation of the horn, resulting in increased pain and in the adhesions of its peritoneal surface.

THE
RELATIONSHIP OF THE NOSE
TO
PULMONARY CONSUMPTION.

By S. HORACE LAW, M.D., F.R.C.S.I.,
Throat Surgeon to the Adelaide Hospital and Surgeon to the Dublin Throat and Ear Hospital.

The object of this paper is to bring forward and collect together some thoughts on the part nasal respiration plays in the prevention of phthisis by adequately clearing the inspired air of infective germs, and in order to render the meaning clear the headings of the various paragraphs which have been compiled in the form of statement and conclusion will be put in tabular form.

1. The tubercle bacillus is always present.
2. It is equally constantly inhaled.
3. The nose is the proper path for respiration and is so constructed that it strains the air passing through it.
4. Infection is less likely when nasal respiration is carried on.
5. Catarrh lowers body resistance.
6. Catarrh is always present in common forms of nasal obstruction.
7. Therefore in cases of nasal obstruction we have lowered resistance and increased chances of infection due to germs inhaled through mouth.
8. Therefore, removal of nasal trouble will eliminate the inhalation of germs to a considerable extent and increase the resisting power.

Special attention of late years has been concentrated on the question of prevention and cure of tuberculous lung disease. Special hospitals and sanatoria have been built and are doing excellent work in curing and alleviating cases, not to speak of their marked effect in teaching their inmates habits of cleanliness, which they take back with them to their homes and thus lessen the spread of infection to those with whom they are brought in contact. Thus, though the opportunities for infection may and are reduced, it is not within the range of possibility at present to isolate all persons suffering from tuberculous disease, so that in daily life every one must be exposed more or less to the bacilli of tuberculosis. That we are not all tuberculous may be set down to the innate power of resistance to invasion present in all living tissue.

The mode of infection in ordinary phthisis has been much debated, and the old theory of direct inspiration of the germs into the lungs is no longer tenable, for if the person be a nose breather the germs have to run the gauntlet of the vibrissæ and the nasal mucous membrane armed with the ever active cilia; again, if he be a mouth breather, the strong probability is, that the germs will be caught on the damp walls of the pharynx, &c., but even supposing that the germs succeed in passing down the trachea the residual air in the lungs will form a barrier to their further advance, and it is difficult to see how they could ever reach the air cells *via* the air passages. We are therefore obliged to look for other paths of infection.

Baumgarten, in the *Wiener Med. Wochenschrift*, November 2nd, 1901, describes some experiments carried out by him, where a typical apical tuberculosis was produced by the injection of tuberculous bacilli into such remote parts as the eye, urethra, bladder, and under the skin, clearly showing that the path of infection must, or at any rate may be by the lymphatics.

Wright, in the *Medical News*, January 19th, 1902, p. 85, says, "We must assume at present that the tubercle bacillus passes into the lymphatics through the mucous membranes of the naso- and oro-pharynx in a very large proportion of cases of pulmonary infection. That tubercle bacilli may be found in the tonsils when no tuberculosis is present in other parts of the body has been demonstrated by Dieulafoy, who inoculated sixty guinea-pigs with tonsillar tissue. Eight of them, 13 per cent., died of tuberculosis; with adenoid tissue taken with the same precautions—that is, that no tuberculous lesion could be found in the subject from which these pieces of tissue were taken—thirty-five guinea-pigs were inoculated, seven, or 20 per cent, succumbed.

To sum up the foregoing we say: That the tubercle bacillus is certain to finds its way into the upper air passages, and that the lymphatics give a ready means of transmission to the usual sites of tuberculous manifestations.

It will be readily admitted that the best protection against infection is a normal nose, allowing proper nasal respiration with its concomitant straining and warming of the inspired air, and a normal function in the glands of the nasal mucous membrane, so that the proper amount of moisture may be supplied and the cilia kept in active working order; the germs will thus most probably be caught and removed, long before they reach the lymphoid tissue, where, doubtless, even if they did arrive in a normal individual, they would soon cease to exist.

How far different must the condition be in a nose whose function is impaired or almost destroyed; in the first place, most of the inspired air passes in through the mouth, and the infective germs are carried straight against the tonsils, pharyngeal walls, &c. Here we have no straining apparatus, and stratified instead of columnar ciliated epithelium, so that it is far easier for the bacilli to find their way into the lymphoid tissue. Here in a healthy subject the resistance of the tissues will overcome most of them, but in the case under discussion we are considering a mouth-breather, and possibly an individual with hypertropied lymphoid tissue. This is clearly not a normal condition, and the power of resistance in the tissues will therefore depend on the amount of deviation from the normal.

In the second place, in all conditions of nasal obstruction, from whatever cause, catarrh to some extent is present, and therefore, following the line of argument above, a lowering of resistance. Osler, in his "Text-Book on Medicine," in the chapter on tuberculosis, mentions, under the heading of "Conditions Influencing Infections," certain local conditions such as catarrh, and says, "How often is a neglected cold blamed as the starting point of the disease." It seems to act by lowering the resistance and favouring the conditions which enable the bacilli to enter the system, or, when once in it, to develop.

If this then is the case surely it is our bounden duty to eliminate as far as possible this weakening of the resisting power. If this catarrh, *plus* whatever condition which caused it can be cured, the patient has had removed one path of infection, and his resistance to germ infection is increased. In the large majority of cases this can be done. Take the very common one of adenoids and tonsils. They are removed, the child improves at once, and the catarrhal condition ceases. Surely we have a right to claim that the power of resisting bacterial invasion has been much increased in this case. The child might never have got tuberculosis, but at any rate a weak point has been strengthened.

Such common conditions as chronic hypertrophic rhinitis, chronic atrophic rhinitis, suppurative disease of the accessory sinuses, polypi, adenoids and enlarged tonsils, all have catarrh accompanying them and are amenable to treatment. Nowadays it is the fashion to have one's nose cleared, and undoubtedly when proper moderation is observed, nothing but good can result, and it is safe to conclude that many are saved from pulmonary tuberculosis by timely attention to nasal respiration, not to speak of the comfort given to the patient at the same time. How much has been and will be done in this direction is hard to say, for it is in prevention of infection rather than in cure after infection that the brightest hope lies. The question of nasal treatment in the tuberculous subject is totally different and involves many serious considerations, such as strength, loss of blood, loss of appetite due to the frequent use of cocaine, and will not be considered here. It only remains to lay stress upon the fact that the coming generation will start out in life with a better chance of escaping tuberculosis by reason of the fact that of one the main paths of infection is now carefully watched and, as far as may be, kept in a normal and healthy condition.

SOME COMPLICATIONS ARISING SUBSEQUENTLY TO CŒLIOTOMY. (a)

By FRED. BOWREMAN JESSETT, F.R.C.S.,

Surgeon to the Cancer Hospital, Brompton.

I have thought the subject I have chosen for my paper might be of interest to the Fellows of the Society, as scarcely a meeting is allowed to pass without the exhibition of numerous specimens of growths or organs removed by cœliotomy. Many of these specimens have been removed only a few days or hours before exhibition, and in a very large proportion of instances the operations are reported to have been attended with a successful issue. It is very rarely, however, that we hear anything of the after history of the patients from whom these specimens have been removed, and I have often thought and wondered if all of them have been so much benefited as they themselves anticipated or the operator could have wished. I think it will be generally admitted that after hysterectomy, abdominal or vaginal, after ovariotomy or even oöphorectomy, or after the removal of the tubes for hydro- or pyosalpinx, it is not uncommon for patients to return in a few months complaining of acute pains, referable most commonly to the region of the pelvis, but not infrequently to other parts of the abdomen. On most careful examination nothing may be found to account for these troubles, and often they are attributed to neurosis, and the patient told that in time her pain will cease, and this undoubtedly in many instances is true, but, too often, the patient continues to suffer for an indefinite period.

It is very desirable, therefore, to try and discover the causes of these troubles, and it is for this purpose that I venture to lay before the Society some of my experiences.

It is probable that in a large number of cases of cœliotomy, subsequent adhesions are formed, most frequently to the parietal wound or to the stump left from the operation, and the frequency with which they are met with no doubt depends somewhat upon the presence of slight sepsis. The more aseptic the operation and the less the peritoneum is injured or manipulated, the less likely are these adhesions to occur, and; if they do occur, they will be slighter and more fragile. I cannot, however, help thinking, that some patients are much more liable than others to contract adhesions. When adhesions have formed, pain is sure to follow to a greater or lesser extent, and the surgeon should when operating bear this in mind, and should pay special attention to the toilet of the peritoneum before closing the wound. He should be careful to see that no blood clot is left either in the pouch of Douglas or between the intestines, and, above all, to be careful to draw down the great omentum over the intestines, as less trouble will arise from adhesion of this than if by any accident a loop of intestine becomes glued to the wound.

If the case be one of ordinary ovariotomy or oöphorectomy, the stump left after removing the cyst, tube or ovary should be carefully stitched over and buried so as to completely cover it in with peritoneum. The same care must be taken in an hysterectomy, the removal of a kidney or appendix, to see that the peritoneum is neatly united over the seat of operation, so as to present no uncovered surface. For this stitching ordinary sterilised catgut should be used, not silk.

The adhesions formed after cœliotomy may not only be the cause of pain and great discomfort, but also of serious peril to the patient. I have in a few cases had to open the abdomen a second time for the relief of pain, and in every case have found adhesions, which on being divided or separated have given relief. I have seen the same thing occur in the cases of other surgeons. I have also had to reopen the abdomen for the relief of intestinal obstruction caused either by a band of lymph stretching across and constricting the bowel, or for a volvulus, the result of adhesion of two portions of the bowel, owing probably to the deposit of a blood-clot. In one case the abdomen was opened no less than five times, thrice by myself and twice by another surgeon. This patient was operated on in the first instance for fibro-cystic diseases of the ovaries, for which oöphorectomy was performed; she made an excellent recovery and left the hospital; subsequently, about three months after the operation, she returned complaining of acute pain and much distension; she was treated for some weeks, but the pain becoming more distressing, she was taken into the hospital and the abdomen reopened; a band of lymph was found stretching from the omentum to the stump of the left side; this band clearly caused constriction of the sigmoid flexure when that portion of the intestine was loaded. The band was ligatured in two places and removed. A good recovery resulted, but in a short time she again returned complaining of acute pain in the abdomen; I being out of town, she migrated to another hospital, where her abdomen was again opened, and the adhesions discovered there were torn down, and a good recovery resulted. She was subsequently, I believe, operated on again by the same surgeon, and more adhesions found. After this she remained well for some considerable period, when she consulted me again, complaining that it was with the greatest difficulty the bowels could be moved, always requiring medicine and enemata, and giving her great pain. On admission the abdomen was distended, especially along the site of the ascending colon, and chiefly at the hepatic flexure. I may say that in the last operation the incision was made over the right semilunar line. From the symptoms it was considered an adhesion probably existed causing either a kink in the colon below the point of protuberance, or a band existed causing constriction. On now operating adhesions, for the fifth time, were discovered along the whole length of the former incision, the omentum was adherent, very much thickened, and drawn considerably to the right, causing the transverse colon to be dragged down, thus creating an acute flexion at the hepatic flexure of the colon, and it was readily seen that if the bowels became at all constipated great pain and difficulty would be caused. The adhesion was carefully divided and the omentum freed, great care being taken in stitching the parietal peritoneum first with catgut and the other layers of the parietes, layer by layer, with specially prepared ten-day gut. The patient experienced immediate relief, and has continued well since, and I trust will remain so.

(a) Read before the British Gynæcological Society on Thursday, October 9th, 1902.

Another cause of trouble after cœliotomy, more especially after hysterectomy, is due to adhesion or kinking of the ureter, or the possible including the ureter in one of the ligatures. This complication gives rise to very great distress with hydronephrosis. In one case I have seen complete occlusion of both ureters, this case was one of very large sloughing fibroid of the uterus in which abdominal hysterectomy was performed. As no urine was voided for twenty-four hours, after consultation it was decided to open the abdomen again, suspecting that the ureter might have been included in the ligatures which was applied to the uterine arteries. On examination, however, it was discovered that the ligatures were quite free from the ureter, but on being tied the tissues were dragged so as to cause a kink in the ureter, which was dilated considerably above. Upon liberating the ligatures the kink was relieved and urine at once passed into the bladder. This case, at the operation on which I was present, made a deep impression on my mind, and convinced me of the wisdom, in any future case when no urine was passed and it was proved by catheterisation that none had entered the bladder, of at once placing the patient under an anæsthetic and reopening the abdomen with a view of examining if there was any constriction or kinking of the ureters.

To avoid possible risk of such an accident I think it is well not to ligature the uterine arteries until the anterior and posterior flaps of peritoneum have been reflected from the uterus, when the vessels are readily felt running up the side of the cervix and can be ligatured without including other tissues. I do not agree with the dictum laid down by some authorities to cut across the vessels before ligaturing and then catch up the bleeding points, as, in the first place, a very large amount of blood will very quickly escape, filling the pelvis, and, secondly, these vessels, from having some considerable tension placed upon them in pulling the uterus with its tumour out of the pelvis, often retract very much, and I have seen considerable difficulty experienced in catching them up, and a large quantity of blood lost before they could be secured.

The fact must not be lost sight of that the appendix sometimes becomes involved, and that all the symptoms of acute appendicitis may occur after the removal of the appendages on the right side. Indeed, it sometimes happens that symptoms of appendicitis precede operation, and when the abdomen is opened the appendix is found adherent to the tube or ovary. I have met with two such cases in my practice; in one the appendix was firmly adherent to the fimbriated extremity of the tube, and in the other it was attached to the ovary apparently where one of the Graafian follicles had discharged itself.

I had occasion to operate on a patient who had had her right tube and ovary removed for a pyosalpinx by a surgeon. She had made an excellent recovery, and all went well for some two or three months, when she was seized with acute pain in her right iliac region and all the symptoms of acute appendicitis. I advised immediate operation, and on opening the abdomen found the appendix firmly adherent to the site of the first operation, and it was with some difficulty that I was enabled to release it; this, however, was safely accomplished and the appendix removed, and the patient made a good recovery.

Another cause of pain is sometimes due to the ovary, one or both of which have been left after an hysterectomy, becoming adherent to and bound down by adhesion to the floor of the pelvis at the line of union of the peritoneum; this I think is more likely to occur when silk is used for the stitching of the peritoneal flaps. I always prefer using catgut specially prepared for this. In case of complete hysterectomy it sometimes happens that a loop of intestine, or more frequently the omentum, becomes adherent to the site of the opening into the vagina, causing, in the case of the bowel being adherent, acute flexion and possible obstruction; this is more likely to occur in cases of vaginal hysterectomy if care is not taken to draw the peritoneal flaps well down into the vagina. In the early days of vaginal hysterectomy I met with two or three such cases.

To avoid the trouble of adhesion I have for some time now used specially prepared catgut for all suturing of the peritoneum, also for ligaturing any vessels or adhesions that may exist, using fine silk only for the ligaturing of the ovarian and uterine arteries. I am most careful to bury all stumps of tumours, and to suture very carefully any portion of peritoneum that may have been torn and cut. The parietal peritoneum I close with a continuous suture of catgut, then place about three to six interrupted sutures of specially prepared gut through the fascia and muscle, letting them be about one inch apart; next I unite the fascia with a continuous suture of catgut, and finally unite the edges of the skin with a continuous suture of fine silk or horse hair. These are removed on the tenth day and a strip of plaster applied.

With respect to the after-treatment, I always, as a routine treatment, give gr. v. of calomel the night of the day after operation, and a soap and water enema on the morning following. The importance of getting the bowels to act within thirty-six or forty-eight hours after cœliotomy cannot be over-estimated, whether by means of calomel or saline aperients perhaps it does not signify, one operator prefers one, another operator likes another. To the late Lawson Tait perhaps, is due the credit for insisting on this, but it will be remembered he introduced the giving of purgatives for the treatment of peritonitis, and here, I venture to think, he mistook tympanitis due to paresis of the bowel, which so frequently occurs after cœliotomies, for peritonitis. Paresis of the bowel and tympanitis, as we all know now, is a very common complication after these operations, especially when there have been many adhesions necessitating the undue manipulation of the intestines; a very troublesome symptom it is, often requiring several doses of aperient, and the repetition of turpentine enemata before a proper action can be obtained. Distension, however, can often be relieved by the introduction of the long tube "per anum," and I am in the habit of allowing a short enema tube to be inserted and left in the rectum, so that the flatus may come away more readily.

Many cases that died after operation in the early days of abdominal section, and which were returned as having died of peritonitis, I am convinced really succumbed to this cause, tympanitis due to paresis of the bowel, owing to the old practice of giving opium with a view of keeping the bowels confined for several days after the operation.

In the limits of this paper I have only ventured to point out a few of the complications that are so often met with after these abdominal operations; had I extended my observations to those complications which sometimes follow operation for gastrostomy, gastro-enterostomy, or other intestinal operations, or for operations on the kidney, gall-bladder and the like, all of which, by the way, are practically outside the domain of gynæcology, a paper of indefinite length might be written.

The questions which naturally arise are what is best to be done for these patients who come to us so frequently complaining of these after-claps. Possibly I may be told by some operators that the methods adopted by them preclude the possibility of such complications; if there are any such I shall be glad to hear how they manage it, as I must candidly admit that I am occasionally confronted with patients who suffer in the way I have described, and have, several times, been consulted by patients so suffering, who have been operated on by others.

The question very naturally arises—What is the best and most appropriate treatment? Personally, I always hold out hopes, unless there are some acute and pressing symptoms in which delay would endanger the patient's life, that the pain, &c., complained of will in time disappear, and, as in many cases it undoubtedly does do so, I should not advise too hasty operative interference.

Should, however, the symptoms continue, and the patient's happiness and usefulness be imperilled, I should not hesitate to reopen the abdomen, and carefully to divide any adhesions that might exist, and either ligature or stitch them over; in dealing with omentum I think it better, after ligaturing, to fold the end over and fix it with a few catgut sutures so as to cover the divided portion with peritoneum, treating the distal end in the same manner if practicable.

One other not uncommon after complication is ventral hernia. This, I am pleased to say, is not so frequently met with now as formerly, and undoubtedly this is due to the greater care which is now taken in the technique of closing the parietal wound and the more rare use of drainage tubes. I have no doubt that the fixing the tissues in distinct layers with catgut, prepared in such a way as to ensure it lasting for some ten days before becoming absorbed, is by far the best method, and I cannot lay too much stress upon the necessity of first being most careful to stitch the peritoneum with a continuous suture so as to prevent any of the tissues being exposed to the peritoneal cavity. For this ordinary catgut is quite sufficient, as the peritoneum finally unites in about thirty-six hours; next, to bring the muscular tissue and fascia together by interrupted sutures of ten-day catgut, and then a continuous suture to ensure the close approximation of the superficial fascia, and lastly, the continuous suture for the skin with horsehair or fine silk.

I never now use silk for buried sutures, as, let it be prepared ever so carefully, it will occasionally give trouble by establishing stitch abscesses, which are not only painful but always tiresome as retarding the convalescence of the patient.

DENTAL SEPSIS AND SYSTEMIC DISEASE.

By HENRY SEWILL, M.R.C.S., L.D.S.,

Past President Odontological Society.

Within the last few years it has become a matter of routine among physicians to refer cases of anæmia and other chronic diseases to the dental surgeon, for a report as to the existence of septic conditions of the teeth likely to be associated as factors in the causation or aggravation of the malady. To this circumstance the fact is due that a very large number of cases of anæmia have latterly passed under my observation, and my interest in the disease having been aroused has been maintained. Dr. Walsh does not need any compliment from me; but perhaps he may not be offended if I venture the opinion that the paper on "Anæmia," contributed to your issue of September 24th, forms one of the best summaries of current knowledge—thoroughly practical, whilst based upon science—that has ever been published. Dr. Walsh, however, whilst strongly emphasising the necessity of attention to the teeth as an early step in routine treatment, does not do more than refer cursorily to this part of the subject.

For effective study of this question it is desirable a correct idea should be had of the pathological conditions of the teeth really capable of contributing to the etiological effects ascribed to them. On this matter some confusion evidently exists. Many writers mention merely dental caries or decay as the disease giving rise to oral sepsis. There is, in fact, nothing in the nature of dental caries itself of a virulently septic character; and it is only in the advanced stages of the disease, when the pulp has become exposed and inflamed, and when the inflammation having extended to the periosteum has terminated in alveolar abscess and necrosis of roots, that serious septic effects can become developed. Caries in its essence consists merely of solution of enamel and dentine by acids, the products of fermenting foreign particles lodged upon the surfaces or within minute inherent flaws in the enamel. As soon as a cavity is excavated it becomes filled with decomposing *débris*, and this no doubt often forms a favourable nidus for the proliferation of pyogenic or pathogenic organisms which enter the mouth from the external atmosphere. How far dental caries can in this stage contribute towards systemic infection remains to be investigated; but at this stage of the disease suppuration does not occur, nor does appreciable discharge of septic matter from the cavities take place. It is impossible to believe that systemic infection could be caused merely by the presence of a few carious teeth with simple cavities full of decomposing organic particles. As soon as the pulp is laid open by caries it becomes more or less inflamed. Its surface may then pour out a minute quantity of foul pus; it may become gangrenous, partly or entirely; and if numerous teeth exist in this state they may, perhaps, constitute an appreciable source of septic infection. When alveolar abscess supervenes, necrosis of roots commonly occurs; and to chronic alveolar abscess, the sequel of caries, may be traced the source probably of the most virulent purulent discharge connected with dental disease. Necrosed roots are equivalent to necrosed bone, and the peculiar infective character of pus from such a source must be always borne in mind. In some mouths there exist numbers of necrosed roots the centres of suppuration, so that the patient is constantly swallowing large quantities of fœtid pus. This condition is very common in young children in whose mouths great part of the first dentition will often be found broken down by caries and the seat of alveolar abscesses.

The dental disease which, beyond all others, is associated with the etiology of systemic maladies, and has been by Dr. Hunter declared capable alone of giving rise to pernicious anæmia, is that known as pyorrhœa alveolaris.

Pyorrhœa alveolaris has no connection with caries. It is a disease of middle life and old age only. It is a process of slow wasting of the alveoli and gradual shedding of the teeth, attended by very slight inflammation and constant discharge of foul pus from within the free edge of the gum and alveolus.

In a large number of cases of pyorrhœa there is a singular absence of caries, and the teeth are often of the best structural character. It occurs in many instances in patients whose care of their teeth amounts to fastidiousness. The malady is extremely chronic; many months elapse before each affected tooth is shed. The disease starts in one or two teeth and gradually affects others not necessarily adjacent, until in the end the whole set becomes involved. Of the etiology of pyorrhœa virtually nothing is known. Knowledge of its pathology is almost equally lacking whilst prognosis is always unfavourable, treatment being rarely able to do more than mitigate the severity of symptoms and slightly check their course. This disease, although common enough in dental practice, is very rare compared with caries.

The symptoms of pyorrhœa begin with a spongy, slightly swollen condition of the free margins of the gums. Front teeth, oftenest those of the lower jaw, are as a rule first attacked. The gums recede, and their recession is often followed by deposit of tartar (ordinary salivary calculus) upon the denuded surfaces of the teeth. Slight inflammation of the peridental membrane is next soon recognisable. Swelling of the membrane raises the tooth and slightly loosens it in the socket, and so pockets are formed around the tooth into which a probe passes easily to a greater or less distance along the root. From these pockets constant discharge of foul-smelling pus or muco-purulent fluid takes place. The discharge in some cases is comparatively small, pressure along the line of the gum being needed to disclose its presence. In many cases the discharge is increased; in a few it becomes profuse.

Besides the masses of ordinary tartar which often—although by no means invariably—are deposited on the teeth there are usually to be discovered small nodules of dense consistency and dark colour scattered over the denuded surfaces within the gum pockets.

The alveoli waste more rapidly than the gum, and the "pockets" become deepened and enlarged. At length each tooth becomes so loosened that the patient removes it with his fingers if it is not forced out by accidental pressure during mastication. Pain throughout the malady is slight until the tooth has become much loosened. Then a jar during mastication will often set up an attack of sub-acute or acute inflammation; and the swelling within the socket rendering the tooth still looser, the patient will often in this condition apply for relief.

The diagnosis of pyorrhœa rarely presents any difficulty. It may, however, be mistaken for alveolar abscess due to caries or injury when only one or two teeth are affected, but there are signs and symptoms which easily differentiate it for those familiar with dental diseases.

In a large number of instances pyorrhœa is associated with disturbance of the general health; it is often present in anæmia. In ordinary cases the general health perhaps suffers most in sensitive patients. In this class the constant discharge of noisome pus, with the consciousness that their breath is tainted and its odour recognisable by others as well as by themselves, are enough alone to cause considerable depression, apart from any effect produced by the constant passage into the stomach of foul purulent discharges. In cases of long standing it is often a question whether the pyorrhœa has arisen from the lowered health or the lowered health from the depressing effect of the local disease. Dr. Hunter seems to ascribe the causation of pernicious anæmia in some cases solely to such septic poisoning. Many patients date their ill-health from the period of development of the pyorrhœa, and in a large number of cases great improvement begins, and the health becomes re-established when vigorous local treatment has been applied, or when the disease has run its course and the patient has learnt to wear and use artificial substitutes for the lost teeth. A certain number of cases are to be observed in which pyorrhœa follows and seems due to the effects of long exhausting illnesses such as typhoid fever. On the other hand, inquiry and investigation fail in most cases to discover any organic or functional disorder capable of giving origin to the pyorrhœa.

With regard to the pathology of this malady there exists one significant fact which seems to dispose of many speculations as to the real seat of the morbid process. This fact is that on extraction of a tooth the seat of pyorrhœa the alveolus at once assumes a healthy condition; the discharge from that particular socket at once ceases; the gum heals normally, and if absorption of the bone continues it is not notably more rapid than under ordinary conditions. These facts point to the conclusion that the disease belongs essentially to the tooth and its periosteum, and is not due to an independent morbid condition of the investing gum and bone. Examination of extracted teeth yields only negative results.

The treatment of pyorrhœa must be first directed to thorough removal of tartar. This, in these cases, is a difficult operation, and can hardly be properly carried out except by a dental surgeon or an operator specially qualified. General antisepsis of the mouth must be assiduously practised by the patient.

A soft toothbrush and a suitable dentifrice and antiseptic lotions must be used. The spaces between the teeth, which become widened as the alveoli waste, should be frequently cleared of foreign particles with a thin quill tooth-pick. In using a lotion the mouth should be partly filled and the fluid forced to and fro between the teeth by the movement of the lips. More direct applications must be made to the necks of the teeth and within the gum pockets around. An aqueous solution of perchloride of mercury, 1 in 3,000, is one of the most efficacious agents, but others may be, of course, employed. The perchloride solution is best applied on tiny twisted ropes of absorbent cotton. The mouth having been thoroughly rinsed (or, better, the pockets around the teeth syringed), access of saliva can be prevented by a folded napkin, and the small ropes of wool saturated with antiseptic can be packed by a small blunt probe around the teeth within the gum pockets and allowed to remain for a few minutes. This can be repeated again and again, care being taken, when a poisonous agent is being used, to make the patient rinse the mouth freely each time the napkin is removed. A great variety of antiseptics have been tried in the treatment of this disease, but probably none can be more efficacious than perchloride of mercury.

Carbolic acid diluted with eucalyptus oil to a strength of one in forty may be used, care being taken to apply the cotton ropes slightly moist only, so as to avoid excoriation of the gums. Sulphate of copper in strong solution or applied in powder to the gum pouches is relied upon by some practitioners; others use permanganate of potash (Condy's fluid). With Condy's fluid good effects are produced. It has the advantage of being practically non-poisonous, and can be entrusted in full strength to the personal use of the patient.

In some cases the patient may be trusted to make the direct application of a strong antiseptic to his own teeth; but in most cases, if the treatment is to be of great service, he must pay frequent visits to the dentist. The assiduous employment of antiseptic lotions by the patient with scaling and occasional more vigorous treatment by the dentist are usually enough to mitigate the worst symptoms, and to prevent the patient suffering severely from the remoter effects on the general health, which this disease, and especially the constant passage into the stomach of fœtid pus are undoubtedly capable of exciting.

Teeth which have become so loose as to be constant sources of irritation should be extracted. This improves the condition of the mouth generally, and often seems to retard the progress of the disease; but extraction of affected teeth, even in an early stage of pyorrhœa, does not put an end to the progress of the disease, nor do more than temporarily check its advance. When numerous teeth have been lost, great comfort will often be afforded by the adaptation of a perfectly-fitting frame of vulcanite to embrace the necks of the remaining teeth, and to hold artificial substitutes in the vacant places. The frames, which for the upper jaw should be on the "suction" plan, must closely surround the teeth without causing any strain upon them. It is well patients should begin to wear artificial teeth before a late period of the disease; so that when the end comes, and all the teeth are lost, they may have acquired the facility to use artificial substitutes which is usually attained only by considerable practice.

In searching for septic conditions associated with dental disease the possible existence of empyema of the antrum must not be overlooked. This disease in a large proportion of cases is caused by chronic alveolar abscesses around roots of teeth the apices of which reach the floor of the antrum, and are separated from the cavity by merely a thin layer of bone. Empyema once established, and pus constantly secreted by the mucous membrane, the antrum cannot be perfectly emptied except by art. Pus flows out when it reaches the level of the natural opening into the nose, or when the head is inclined forwards; but in recumbency the discharge may find its way *via* the posterior nares into the pharynx. The pus is always foul, mostly horribly fœtid. In many cases patients suffer for months or years before a correct diagnosis of their disease is made. During all this time the patient, from six to eight hours out of the twenty-four, may have been swallowing a quantity of virulently septic matter sufficient in itself perhaps to give origin to the grave systemic diseases ascribed by so many competent observers to such simple causes.

THE FIRST STAGE OF LABOUR
IN RELATION TO
UTERINE RUPTURE.

By ERNEST HASTINGS TWEEDY, F.R.C.P.I.,
Late Assistant Master, Rotunda Hospital, Dublin; Gynæcologist, Steevens Hospital; Lecturer in Midwifery to the Queen's Jubilee Nurses.

The first stage of labour can correctly be stated to comprise the period in which the os is in process of dilatation; its beginning is not so easily indicated, nor has its ending been defined with precision Dr. Berry Hart has pointed out the futility of considering painful contractions of the uterus as indicative of its commencement. A uterine contraction without pain is certainly no indication, nor yet can the presence of a show—*i e.*, blood-stained mucous discharge—with accuracy be said to mark its origin. Again, cervical dilatation is of no trustworthy significance, for a patulous canal is not infrequently present long before labour begins. It seems to me that an accurate definition of the commencement of labour must take cognisance of that peculiar phenomenon known as uterine polarity. If this be so, then a contraction of the body of the uterus, accompanied by a relaxation of the circular fibres in the cervix, the processes being interdependent, will mark the commencement of labour.

The occurrence of uterine polarity does not seem to have received any sufficiently reasonable explanation; the one I now offer has, at all events, the merit of simplicity.

The arteries, veins and nerves which pass through the lower uterine segment must be subjected to a considerable amount of stretching force during the sudden increase of its area, brought about by a labour contraction. That the circulation suffers is evidenced by the serous infiltration and softening of the cervix, a result of impeded venous return. Hence congestion occasionally terminates in rupture of the vessels and the formation of a cervical hæmatoma. In a similar manner there seems little doubt that the nerves must be affected. Nerve impulses are easily inhibited by the over-stretching of a nerve, and when once this takes place a paresis of the circular muscle fibres in the cervix to which these nerves are distributed will occur.

A consideration of these views makes the etiology of uterine polarity quite understandable, and affords us a scientific basis for determining the onset of labour.

If we now turn to the ending of the first stage of labour, I find myself in sharp disagreement with the generally received definition of it—viz., that it terminates when the os is fully dilated. It is in my opinion erroneously held that a fully dilated os is at all times capable of permitting the passage of the fœtus through it. Abundant evidence is forthcoming to show that this is not so. Our dispensaries teem with patients suffering from torn cervices, the result of so-called normal delivery, Some of these, no doubt, may fairly be considered to result from misdirected efforts on the part of the attendant to hasten delivery, but a large number still remain that cannot be accounted for in this manner. These are the cases in which the first stage of labour has not ended on the full dilatation of the os, but rather at the time of the tearing of the os to permit of the passage of the fœtus through it.

This condition, induced by tension, may be more readily understood if we call to mind the somewhat analogous process which is observable in phimosis. If the blades of a forceps are pushed through the orifice of a phimosed prepuce, and then opened with force so as to bring about full expansion of the ring, we find that it assumes hard and rigid characteristics, with a knife-like, unyielding edge. Similarly, the os stretched to its fullest expansion becomes knife-edged, with thin, unyielding walls, and we speak of the condition as "rigidity of the os." When once the os has reached this stage of expansion it tears with the greatest facility, either spontaneously or in consequence of manipulations, carried out, perhaps, in the gentlest manner possible. This rupture, moreover, is hard to recognise as such by the fingers of the examining hand even during the process of its occurrence. An apparently very rapid dilatation is felt resembling closely the sudden relaxation of a spasmodic stricture.

It is probable that in this way arose the erroneous notion that a rigid os is the result of a muscular spasm. A moment's thought will demonstrate the untenability of such a theory. The fact that in spite of this so-called muscular spasm the os remains open, though the functions of the contracting muscle is to cause its closure, is sufficient to show the impossibility of associating in any causal connection the conditions one with the other. There seems little reason to doubt that a rigidity such as I have described indicates an expansion of the os to its utmost limit, short of a solution of continuity taking place.

An os in this state, incapable of further expansion, is still subjected to the pull of the uterine contractions throughout its entire circumference. These contractions are not equally effective in all directions. In the tug of war that takes place between them the posterior fibres gain the mastery of the others, the result being that the posterior cervical lip is taken completely up and becomes continuous with the post-vaginal wall. If the os cannot expand, it is evident that it must follow in the wake of the disappearing posterior cervical lip, and thus we find it moving in a direction upwards and backwards, dragging in its progress the anterior cervical lip after it, and causing that structure, in common with the anterior lower uterine segment, to thin out more and more. This thinning, brought about as just described, is at times so extensive that it closely simulates unruptured membranes, and may give the mistaken impression that the os is fully open. I have even known an attempt to be made to apply forceps under such circumstances. A cervix drawn out and thinned in this manner is erroneously said to be incarcerated, or nipped between the pubes and presenting part of the fœtus, and thus its inability to retract is accounted for. It is highly improbable that nipping of the cervix between the smooth pubic walls and the equally smooth fœtus is, under the conditions generally present, possible. Moreover, were it so incarcerated its liberation would be attended with infinitely greater difficulty than is experienced in the manipulation ordinarily advised for effecting this purpose. This manipulation not infrequently results in the tearing of the cervix.

If these views are accepted, it becomes at once evident that the ending of the first stage of labour cannot without exception be defined as occurring when the os is fully dilated.

The elongated anterior cervical lip set free by rupture becomes rapidly œdematous during the further progress of labour, and is occasionally found protruding through the vulva after delivery.

It is extraordinary to note the slight extent to which this complication has arrested the attention of obstetricians. It has been wrongly described as a hæmatoma of the cervix, and I have known of one instance in which it was torn from its attachments, under the mistaken impression that a portion of adherent placenta was being dealt with.

So far I have described rigidity of the os and the events which follow from it in cases of primiparæ. In them the infra-vaginal cervix is the weakest portion of the uterus, and its readiness to tear lessens the liability of the organ to rupture elsewhere.

In multiparæ, on the other hand, the deposition of fibrous tissue in the neighbourhood of old lacerations often renders the cervix exceedingly tough and inelastic, and thus interferes with its dilatation. Under these circumstances we have as a result of this moving upwards and backwards of the os great thinning of the anterior cervical lip. This lip will be formed by the anterior fornix of the vagina below and the anterior lower uterine segment above, the two structures lying one on top of the other. In the event of the os neither dilating nor yet tearing, a rupture of the lower uterine segment and vaginal vault is very likely to occur, as they become more and more thinned out by the pressure downwards exerted on them by the presenting portion of the fœtus and the counter forces exerted by uterine muscles at either side. Occasionally, however, it is the posterior fornix and posterior lower uterine segment that are torn. This can be explained by remembering that the uterine and posterior vaginal walls become continuous after the taking up of the cervical lip. The uterus thus may drag itself free from the vagina, the tear being continued into the cervix and up to the lateral walls of the uterus.

It is a curious fact that three-fourths of uterine ruptures which have been reported as occurring in Dublin within the past ten years were complicated by vaginal tears, while such ruptures are by no means the kind most commonly met with elsewhere, as all statistics show. Another point of interest in connection with our Dublin cases arises from the insidious method of their occurrence. Observer after observer has noted that in many instances the catastrophe was not preceded by signs which we are taught to associate with impending rupture. Moreover, it is in those cases in which the vaginal tear complicated the rupture that an absence of premonitory symptoms was noted. In consequence of the rarity of pelvic contraction among us, uterine rupture is not often encountered. The cases reported favour the belief that rupture takes place not often as a complication of the second stage of labour, but of the first.

Should these views be accepted, then the moving upwards and backwards of the os, which at the commencement of labour had been centrally situate, might well be regarded as a premonitory sign of rupture.

To summarise the points which to me seem of interest:

1. The first stage of labour begins when the polarity of the uterus is established.
2. Uterine polarity results from an over-stretched condition of the nerves which course through the lower uterine segment, and are distributed to the circular muscular fibres of the cervix. The painless uterine contractions and retractions of pregnancy thin out and stretch the segment, and thus ultimately induce polarity.
3. The cervix being fully dilated does not necessarily imply a sufficiently open os to permit of the passage of the fœtus.
4. The anterior cervical lip is not easily nipped or incarcerated between the pubes and the descending fœtus. The cause of its elongation is due rather to the retraction of the posterior cervical lip and the consequent dragging upwards of the os, which cannot sufficiently dilate to permit the passage of the fœtus through it.
5. Such an os will in the case of primiparæ rupture almost certainly in order to permit of the commencement of the second stage of labour—*i.e.*, an expansion sufficiently large to permit the passage of the greatest diameter of the presenting portion of the fœtus through it.
6. Such a laceration cannot be treated by immediate suture, not alone because of the great œdema of the anterior lip, but chiefly for the reason that the posterior lip is taken up, and there is therefore nothing to which to stretch it.
7. A multiparous cervix is not always the weakest portion of the uterus. When this is so, a uterine rupture occurring as a consequence of rigid os will be preceded by none of the usual premonitory symptoms, and the tear will be most likely to involve the vagina.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

Meeting held Thursday, October 9th, 1902.

Frederick Bowreman Jessett, Past-President, in the Chair.

Specimens.

Professor J. W. Taylor, Birmingham, showed a recent specimen of

TUBAL GESTATION

in which at one end of the tubal sac was seen a congeries of large dilated thin-walled vessels which appeared to be on the point of bursting. The specimen suggested a form of rupture which at present had not been recognised—the rupture, not so much of the tubal sac as of the greater vessels at the placental site. Such a rupture would probably be attended by rapid and excessive bleeding, and its special character escape recognition when the hæmorrhage had caused the vessels to collapse.

Dr. **Macpherson Lawrie**, of Weymouth, showed a large

PYO-SALPINX

removed from a woman, æt. about 20, three months after her marriage; it had not led to any pelvic symptoms, and had been discovered by accident. He also showed two fibroids removed from sisters, æt. 37 and 39 respectively; both patients did well. A third sister had been operated on in St. Thomas' Hospital, and two others were awaiting operation for the same kind of tumour. There were nine sisters in the family: five had suffered from cataract and three from both cataract and fibroid tumours. He did not know of any connection between the two affections, but the history was an unusual one. The women were all unmarried, except the one operated on in St. Thomas' Hospital; he had no information as to children.

Mr. **Bowreman Jessett** showed

FOUR CASES ILLUSTRATING THE SIGNIFICANCE OF UTERINE HÆMORRHAGES DUE TO TUMOURS.

The four specimens are all from cases in which the question of uterine hæmorrhage was an important element in the diagnosis. (1) The first is a uterus removed by vaginal hysterectomy on account of carcinoma of the body. The patient was a woman, æt. 38, with a family history of phthisis but none of cancer. She was the mother of five children; all her confinements, though followed by debility and once by a mammary abscess, were fairly easy. Menstruation, established at seventeen, was irregular (six to eight weeks) with a scanty flow, but had latterly been more regular. She had been fairly healthy, but seven years ago had rheumatic fever, to which perhaps might be attributed a mitral duplication of the first sound of the heart. She was habitually constipated, her motions being hard and occasionally bloodstained, but had had attacks of diarrhœa. She came under my care in April, 1902, complaining of pain in her left side extending into the groin, and a foul yellowish discharge from her vagina. She said that about twelve months previously she had noticed this discharge, and had been sick in the morning on rising, and suffered a good deal of pain, which, however passed away after a couple of hours. After a time she found that she could not hold her water, and consulted a doctor, but had no treatment except vaginal douches. The discharge stopped for a time, but returned with increased severity and more pain, and she therefore came to the hospital. Beyond the fact that there was tenderness in both iliac regions, nothing was elicited by external examination. Internally, the cervix, hard and fibrous to the touch, was directed forwards, the uterus was not tender, but one ovary was prolapsed. *There was slight bleeding on examination.* On May 5th I removed the uterus and a cystic ovary through the vagina. She was discharged convalescent on June 2nd. On opening up the uterus the fundus was found to be the seat of carcinomatous deposit. (2) The second specimen, a comparatively small uterus with a number of sub-peritoneal fibroids, was taken by abdominal section from a single woman, æt. 35, admitted to the Cancer Hospital, June 28th of this year. The patient left the hospital convalescent on August 1st. (3) The third specimen removed from a sterile married woman, æt. 50, with a family history of cancer, is a uterus containing a large sub-mucous fibroid. She was admitted to the hospital on March 15th, 1902, complaining of inability to hold her water, abdominal pain of a gnawing character, and hæmorrhage from her vagina, occurring every fortnight and persisting for about a week. Five years previously she had had displacement of her uterus from lifting a heavy weight, and two years later suffered from a dragging pain in her abdomen, and found some difficulty in holding her water. On March 15th abdominal section under ether; the tumour was brought out of the abdomen with a myoma screw and removed, the stump covered with peritoneum and the abdominal wound sutured in layers. This patient did well for the first week and then suddenly collapsed, dying on March 24th. In this instance the hæmorrhage had been profuse and had been going on for three years. (4) The fourth specimen is also a submucous fibroid, and was removed from a woman, æt. 42, admitted to the Cancer Hospital on May 1st, 1902. Except for neuralgia she had always had good health till eight years ago when, after lifting a heavy weight, she felt faint, had profuse flooding, with large clots, and for two days great pain; after a week in bed she quite recovered and the bleeding did not return. In April, 1901, she found that her womb had fallen and projected to the size of an egg outside her body; it was replaced by a practitioner, who kept her in bed for a week, and she wore a ring till January 19th, when she was attacked with severe abdominal pain and could not pass water, which had to be drawn off for several days, and she was recommended to come to the Cancer Hospital. The lower part of her abdomen was then swollen and showed striæ, but the umbilicus was normal; a distinct tumour, as large as a cocoa-nut, could be felt in the right iliac region and extended towards the umbilicus; it was movable, hard, and without fluctuation. The tumour was removed by abdominal hysterectomy on May 20th, and the patient was discharged well on June 21st. In this case, with the exception of the single flooding eight years ago, there appears to have been no abnormal bleeding whatever.

Professor J. W. **Taylor** read a short communication upon a case of

UTERUS BICORNIS WITH RIGHT RUDIMENTARY HORN

which will be found on p. 427.

Dr. **Hodgson** asked whether it was absolutely certain that the specimen was a bicornual uterus; whether the condition might not have arisen in salpingitis; and whether the pain on the fifth day after the onset of the period might not be connected with the natural shedding of the uterine mucosa after menstruation.

Professor **Taylor** was quite certain that the condition was as he had described it. He had himself at first thought that the tumour might be a portion of the tube, but that idea was negatived by the fact that the round ligament was present only to the outer side of the tumour, and by the careful examination, made by Professor Leith, which showed that the structure of the walls and lining membrane of the cavity resembled that of a normal uterus rather than of a tube. Microscopically there was no trace of any communication between the cavity and the other horn. As regards the pain, no doubt at the onset of the period a process resembling menstruation took place in this cavity, though there was no blood, and the maximum distension by the accumulation of fluid was reached on the fifth day, when the size of the tumour was greatest; the pain diminished as the swelling subsided, but the addition of some peritoneal inflammation caused adhesions, and the attacks tended to increase in severity.

Mr. **Bowreman Jessett** then read a paper "On Some Complications arising subsequently to Cœliotomy," which will be found on p. 429.

Dr. **Macpherson Lawrie**, in thanking Mr. Jessett for his interesting paper, said that nothing could be more profitable than to report the after results of abdominal sections. He never himself felt happy till the patient's bowels had acted, and usually gave two ounces of castor oil which, in emulsion, was easily borne, and prompt and satisfactory in its results. In obstinate cases of sickness it should not be forgotten that the stomach tube was available; he had used it with the greatest advantage for emptying and washing out the viscus, and the method was worthy of more frequent adoption. He strongly advocated the use of swabs instead of sponges, having altogether abandoned sponges himself.

Professor **Taylor** concurred with Mr. Jessett that trouble after abdominal section was most commonly due to adhesions, he had cases in which the adhesion of the appendix or omentum to the stump of an ovariotomy, or of a loop of small intestine to the cut surface of the ovary after a conservative operation, had necessitated the reopening of the abdomen. He had used fine (ophthalmic) silk for buried sutures, especially so in resections of the bowel, and thought, where it was equal to the strain, it was as satisfactory, as easily absorbed, and as little irritating, as catgut. In one instance, in which the patient died from apoplexy some days after resection of the bowel, he had been able to verify this opinion. Like Dr. Lawrie, he preferred gauze swabs or pads to sponges, as they could be perfectly sterilised by superheated steam; his own were made in different sizes, of fifteen thicknesses of gauze, and held fluid well. In the obstipation and distension of the abdomen met with after abdominal section, too much influence, in his opinion, had been attributed to paresis of the intestine, there was often some peritonitis, and many cases could be saved by enemata and careful nursing. In regard to hernia, happily, since the practice of suturing the abdominal wound in layers had obtained, it was not so frequently met with; if one had not to use a drainage tube and an exact suture could be made for the whole length of the wound, perfect union would result. He used silk for the peritoneum, and passed silkworm gut through the muscles, fascia, and integument, sometimes using silk again for the fascia. The worst cases of hernia were in the days when the clamp was employed in hysterectomy.

Dr. **Richard Smith** quite agreed with Mr. Jessett's method of suturing the abdominal wall. At the Hospital for Women, Soho Square, the practice was to close the peritoneum with a continuous catgut suture, the fascia with stronger catgut, and the skin with fine silk or horsehair. He had for some years been convinced of the importance of paying attention to the condition of the stomach in cases of intestinal trouble. The stomach in many cases became dilated, a condition that was sometimes attributed to the anæsthetic and to the long time the patient was kept under it, perhaps two hours or more. Moreover, a prolonged liquid diet was apt to lead to gastric dilatation, feebleness and pain. Great relief would then be afforded by washing out the stomach.

Mr. **Charles Ryall** remarked that from his experience in reopening the abdomen after operations, he was struck by the fact that the adhesions he met with in former years were much firmer and more extensive than those usually found at the present day. This he attributed to the improvements in abdominal procedure; in earlier days antiseptics were almost invariably employed; now normal salt solution or sterile water was used if the abdomen was washed out at all. Adhesions might, however, be due to injury to the intestines from exposure to air or from excessive manipulation with the hands or with sponges; such injury led to stasis in the circulation and effusions into the peritoneal cavity, and when adjacent parts remained in undisturbed contact for any length of time, adhesions followed as a matter of course. Apart from that, there was apt to be stasis of the intestine, at all events as regards its contents, and hence the necessity for an early evacuation after operation, which should empty the bowel, stimulate the circulation, and re-establish the normal physiological condition of the parts.

Dr. **Hodgson** said, that after ether narcosis there was often a large amount of bilious secretion in the stomach, he thought that one of the reasons a purgative administered soon after operation was so beneficial, was that it carried away any such accumulation.

Mr. **Mansell Moullin** had been fortunate in having little personal experience of adhesions after operation. As bearing on the alleged influence of sepsis in their formation and the propriety of washing out the abdomen, he mentioned a case of double pyo-salpinx on which he had operated recently; he had washed out the peritoneal cavity, and had closed the wound in his usual way, and the patient recovered perfectly and was on the point of leaving the hospital a month afterwards, when symptoms of obstruction declared themselves and he had to open the abdomen. There were adhesions in every direction; one coil of intestine adherent to the stomach formed a constricting band, which had caused gangrene of the bowel. He resected the bowel, but the patient did not recover. He sometimes washed out the stomach, and was in favour of allowing the patient to drink freely after the anæsthetic: tea seemed to be the most grateful beverage, and if the patient did bring it up no harm was done.

Mr. **Jessett**, in reply, said that as regarded aperients he pinned his faith upon calomel, and approved of the routine practice of giving five grains on the morning after operation and repeating the dose if necessary. If the bowels were not relieved by this, and there were much distension, he would rely upon a saturated solution of sulphate of magnesia injected into the rectum. Dr. Macpherson Lawrie's suggestion as to clearing out the stomach was a valuable one, especially if vomiting were persistent. He had formerly practised the through-and-through suture of the abdominal parietes, but was now a complete convert to the method of suturing in layers, and thought the most important step was to secure the accurate approximation of the aponeuroses of the recti. He did not think it greatly mattered whether one used swabs or sponges so long as they were clean and antiseptic; personally he preferred sponges to work with, as he had found swabs apt to crumple into little lumps; swabs, however, offered the advantage that they only required thorough boiling to make them aseptic. He was sure that drainage through the wound was one of the chief causes of ventral hernia; undoubtedly, a better way of drainage was through the vagina. He thought it a mistake to wash out the abdomen, and never did so even if a pyo-salpinx broke under his hand, but made a most careful toilet of the peritoneum and inserted a drainage tube through the vagina.

OBSTETRICAL SOCIETY OF LONDON.

Meeting held Wednesday, October 8th, 1902.

Peter Horrocks, M.D., President, in the Chair.

UTERINE CANCER.

Dr. **Cuthbert Lockyer** referred to a case of uterine cancer brought before the Society last year. The history was as follows: E. H., æt. 35, married twenty years, had three children, was last confined fifteen years ago, had last abortion four years ago. Since 1901 she has never been well. She had had much hæmorrhage and pain in left side, and had had to take to bed. There was also a yellow discharge. When first seen patient was anæmic and weak. The body of uterus was enlarged. Examination showed no evidence of growth. A large dose of ergot was given, and further examination showed a large growth about the size of a hen's egg projecting from cervix into the vagina; both lips were affected. The patient was operated on in 1901, great difficulty being experienced in reaching the pouch of Douglas. The fundus uteri was drawn through the opening, and the suspected tissue removed. The vaginal wound was not closed, the ligature left long, and the opening plugged with gauze. A month later there was a recurrence of growth in the recto-vaginal septum, and patient died May, 1902, five months after operation. The uterus was shown, the growth being seen to extend into the internal os, but not to involve the body of uterus. Microscopically it appeared to be a squamous-celled epithelioma.

Dr. **Rose** expressed the opinion that when disease had passed beyond the uterus no operation was of any good.

The only trustworthy operation consisted in the removal of the entire uterus. Eight cases he had treated for cancer of cervix had remained free from recurrence for from four to fifteen years.

Dr. **SPENCER** was of opinion that recurrence rarely took place in the stump. He considered the best operation for cancer of cervix was to remove the cervix high up as well as part of the body, with the galvano-cautery. High amputation preceded by steaming was good. It was not, however, safe to cauterise the broad ligament.

Dr. **DUNCAN** considered that everything depended upon the extent of the disease. The cause of the great mortality was because surgeons did not hesitate to operate even when the vaginal walls and the pelvic glands were involved.

VAGINAL REMOVAL OF OVARIAN TUMOUR.

Mr. **JOHN W. TAYLOR**, Birmingham, showed specimen of an ovarian tumour removed by vaginal section from a woman two months advanced in pregnancy. Transfixion of pedicle and closure of the opening by continuous suture was the method adopted. This method was chosen in order to avoid the necessity for any abdominal wound, and the patient did well. On the fourth day after the operation the patient aborted. The chief point to be noticed, he observed, was that vaginal removal did not afford immunity against abortion.

CANCER OF BODY OF UTERUS.

Dr. **LEWERS** then showed a specimen of cancer of the body of the uterus in a single woman, æt. 55. The history dated back six months, the symptoms being a watery blood-stained discharge, but very little pain. It was impossible to remove the growth in one piece by vaginal hysterectomy, so pan-hysterectomy was performed. Before abdominal section a ligature was passed round the internal os.

Dr. **DUNCAN** remarked that in this case he thought the right plan was adopted, and that ligature of the os was a good plan before panhysterectomy.

Dr. **HORROCKS** added that he always resorted to this plan in order to prevent the contents of the uterus passing downwards in panhysterectomy.

SPECIMEN OF GRAVID UTERUS.

Dr. **VICTOR BONNEY** showed specimen of uterus with child, in the second stage of labour. The woman, æt. 29, primipara, was attended by a midwife. On opening the abdomen the uterus was found pressing on the child, the head of which could be felt through the vagina. All the liquor amnii had drained away. The speaker was struck by the flaccidity and looseness of the parts The child, in the third position, was freely movable; there was a total absence of vaginal cervix, and great difficulty in distinguishing the lower uterine segment.

SARCOMA OF UTERUS.

Dr. **McCANN** then showed a specimen of uterine sarcoma from a woman, æt. 53, who had ceased to menstruate twelve months previously. There was very severe hæmorrhage every three or four days for five months. Urine albuminous, the quantity increasing until it became almost solid on boiling. No secondary growth in lungs or pelvic organs. This was, he thought, probably a deciduoma, which is rare after the menopause.

CARCINOMA OF GRAVID UTERUS.

Dr. **DUNCAN** showed a specimen of a gravid uterus at the third month of gestation with epithelioma of cervix. The patient, æt. 34, for three months previously, had had a period every fifteen days, after which, for two months, nothing but a yellowish discharge. The uterus was freely movable. There was an epitheliomatous condition of cervix. The uterus was removed by vaginal hysterectomy, and patient was doing well.

A CASE OF CHRONIC INVERSION OF THE UTERUS.

Dr. **TAYLOR**, Birmingham, next related a case of chronic inversion of uterus of seven months' duration, irreducible by Tait's repositor (of the same kind as Aveling's repositor), causing dangerous hæmorrhage and severe vomiting. The patient had been married two years, and had her first child in 1899. Labour was tedious and difficult, and since then she had never been quite free from hæmorrhage. This had lately increased in frequency. She was examined by Dr. Buxton, who detected a tumour in the vagina. On entering hospital she was in the last stage of anæmia, and was nourished by nutrient enemata every four hours. On examination, a pear-shaped tumour was felt in the vagina, completely obstructing the vaginal canal. It was impossible to feel the fundus uteri through the abdomen, and there was found to be complete inversion. In September, 1899, the previous diagnosis of tumour in vagina was confirmed. The orifices of the Fallopian tubes could not be seen. A tranverse incision was made with scissors in the usual way, and the peritoneum was pushed up. After opening the peritoneum an attempt was made to reduce the inversion, this, however, being found impossible. An incision was then made in the anterior wall of the uterus and the inversion reduced, the incision being afterwards sutured with sterilised silk and a plug of iodoform gauze being placed between uterus and bladder. After a week the wound suppurated. Patient completely recovered. It was interesting to note that there was no definite line of demarcation between the uterus and the vagina. It would, perhaps, he suggested, have been better to cut a wedge-shaped piece of uterine wall from the body of uterus.

Mr. **BUTLER-SMYTHE** asked why Aveling's repositor had not been tried in this case? It was almost always successful, and was a simpler and more trustworthy instrument than that introduced by Tait; the former, being without any spring, was, moreover, less liable to slip during the attempts at replacement.

Dr. **HEYWOOD SMITH** suggested that in cases of chronic inversion of the uterus intermittent squeezing of the inverted fundus, though tedious, was in many cases very effectual—pressure tending to empty the blood vessels and causing the muscular tissue to relax. If pressure were then made with the thumb at the orifice of one of the oviducts where the uterine tissue was thinner, it was often comparatively easy to reduce the inversion.

Dr. **HANDFIELD-JONES** dissented from the line of treatment adopted in this case. In a similar case under his care, in which the inversion was so acute that no line of definition between the vagina and the end of the cervix could be made out, the uterus hung as a pear-shaped mass from the vaginal roof, and the finger passed from the vaginal mucous membrane on to the cervical mucous membrane without the possibility of distinction. As in the author's case, difficulty had arisen owing to the womb being so movable that it was extremely difficult to keep the cup of the Aveling's repositor on the uterine body. By packing swabs round the womb in the upper vagina and by patient watching reposition had ultimately been effected. The result of the operation in the author's case was to leave a long, weak scar in the anterior uterine wall, and this might be a source of danger if the patient became pregnant. He asked whether removal of the womb by the vagina would not have been a shorter, simpler operation, and attended by less shock.

Dr. **HERBERT SPENCER** held that there was no method of reducing an inverted uterus to be compared with reposition with Aveling's instrument, the cases being very rare in which the instrument failed. The difficulty due to the cup slipping off the fundus was present in many cases. In one case of the kind he had held the instrument in place, and had then rapidly reduced an inversion, which was previously very obstinate. He agreed with Dr. Heywood Smith that, with patience, continuous pressure (with Aveling's instrument) would overcome the resistance of the uterine muscle and restore the organ in nearly every case.

Dr. **DUNCAN** inclined to the opinion that if Aveling's repositor had been applied to the inversion, and kept there by packing the vagina carefully all round, the inversion would probably have been reduced.

Dr. **BLACKER** asked why the author had incised the uterus anteriorly, instead of adopting the plan of first opening Douglas's pouch and attempting reduction after separation of the adhesions as recommended by Kustner. In a recent case of his own, where he had reduced a chronic inversion of some four months' standing by Aveling's repositor, the patient again became pregnant and had recently been delivered of a child at term. As these cases usually occurred in young women, who might subsequently become pregnant, the danger of rupture of the uterus was considerable, more especially when it was necessary, as in the author's case, to carry the incision from the fundus uteri to the external os.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, October 19th, 1902

TRACTION OF THE TONGUE IN POISONING.

IN referring to the death of Zola, M. Labord spoke, at the meeting of the Académie de Médecine, on the utility of rhythmical traction of the tongue in poisoning by carbonic oxide, by means of which Mme. Zola was resuscitated after twenty-five minutes of patient efforts. The speaker insisted particularly on the necessity of provoking by mechanical means the respiratory reflex, to obtain a favourable result. If the treatment is limited to giving inhalations of oxygen without having recourse to either traction of the tongue or artificial respiration by Sylvester's method, failure is certain.

EXTRA-UTERINE PREGNANCY.

M. Picque, at the Société de Chirurgie, communicated three cases of extra-uterine pregnancy. One of the cases was attributed at first to appendicitis, whereas in reality it was a case of rupture of the pregnant tube. M. Legneu said he made the same mistake in two similar cases.

EPILATION AND OXYGEN WATER.

According to Dr. Gallois, the application of oxygen water is a ready and inoffensive method of removing superfluous hair from the face and ephelides. A piece of cotton wool moistened with the solution is applied to the region for a few minutes once a day. In a short time the hairs begin to grow pale, and finally become an imperceptible down. In continuing the treatment long enough the hairs disappear, but are not entirely destroyed, as they break off near the roots. Consequently it is necessary to renew the applications from time to time.

In any case, this method possesses the advantage over the ordinary methods employed against hypertrichosis (epilation by instruments, electrolysis, epilatory pastes) of being simple, painless, and innocuous.

GONNORRHŒAL RHEUMATISM.

In speaking of the treatment of blennorrhagic rheumatism, M. Dezanneau drew attention to three points: importance of treating the urethritis; the good results obtained from local turpentine baths, and the indications for surgical treatment.

As regards the first, injections, or, what was better still, abundant washings out of the urethra, were absolutely necessary. The agents used were various—sublimate, rethyal, nitrate of silver—and gave good results, but he preferred permanganate of potash in 1-4000 or 2-4000. The injections shouldb e practised twice a day, and a quart of the weaker solution used each time for the first few days gradually, and when the urethra can tolerate it the stronger solution could be used. The local treatment generally sufficed to effect a cure, otherwise the usual internal remedies might be prescribed at the same time.

When in the course of the gonnorrhœa, rheumatism sets in, the limb should be placed in a position of complete rest, and the ice-bag applied or ointments. M. Championnèire applied mercurial ointment, covered with cotton wool, and a bandage. Kuel preferred compressed web, with the following solution:—

Salicylic acid, ʒiv;
Proof spirit, ℥iij;
Castor oil, ʒvj.

Balzer recommends the following ointment:—

Salicyclic acid
Laoline } ʒij;
Ess. of turpentine
Lard ℥ijss.

When the acute period has passed local revulsion came in. For that purpose M. Dezanneau employed:—

Black soap watery emulsion } ℥iv.
Ess. of turpentine

In certain cases of polyarthritis he prescribed turpentine baths, a half-pint for a bath of ten to twenty minutes.

Surgical intervention was indicated in two cases only: in purulent arthritis and in acute serous arthritis of a grave type. In purulent arthritis the articulation should be opened, and from one to two drachms of sublimate solution (1-4000) injected. That treatment has been highly recommended by Balzer. As to internal medical treatment, M. Dezanneau considered it of but little use. Salicylate of soda, antipyrine salol, salophene, iodine, &c., had been tried, but none of them gave satisfaction.

THE NURSING PROBLEM IN FRANCE.

The expulsion of the Sisters of Mercy from many French hospitals left a void which, so far, has not been adequately filled in respect of the nursing staff. This had to be hastily recruited from women of the lower classes who undertook the duties, the proper performance of which infers much devotion and self-sacrifice, merely as a livelihood. The results have been disastrous, and strenuous attempts are now being made to elevate the calling of hospital nursing into a profession to which might with propriety belong young women of the better educated classes. There are many difficulties in the way inherent to French social conventions, but if placed on a sound or respectable footing there is reason to hope that the career may be embraced by women who find in nursing something more than a mere *gagne pain.*

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, October 18th, 1902.

THE *Archiv. f. Kl. Med.*, 73 Bd., pp. 411-421, contains the report of a case of

NEURITIS OF THE SPLANCHNIC NERVES,

by Prof. H. Stilling. The chief complaint of the patient, a man of 40, was an enormous swelling of the abdomen due to ascites. There was also swelling of the extremities, but not in a degree corresponding to the amount of fluid in the abdomen. Several litres of fluid were removed by an exploratory incision. Considerable and uniform enlargement of the liver was discovered. A drain was left in the wound. Death eventually took place from cardiac failure. At the autopsy the liver was found much enlarged, reaching to the iliac fossa.

It was extraordinarily vascular, and slightly granular on the upper surface. There was marked emphysema of the lungs, with a fresh red infarct in the lower part, and an embolus in the corresponding arterial branch. Heart large, right ventricle dilated and hypertrophic; dilatation of the left ventricle. There were also found marked neuritic changes in both splanchnic nerves. A longitudinal section of the right nerve showed an extraordinary absence of the dark marginal fibres, and only a few of the medulla-containing fibres were intact. The changes in the left nerve were not so advanced, but a number of degenerated fibres were observed in them. There degeneration could be followed up to the cœliac ganglion, in which, apart from a diminution of the thick primitive fibres, no important changes were noted. The prominent symptoms of ascites and static hyperæmia of the liver could not be explained by the cardiac condition, but its cause must be sought in the neuritis of the splanchnics, which was a disease independent of the heart and lungs. The cause of the nerve disease was not known. The great hyperæmia of the liver was due to the paralysis of the splanchnics, and this was aggravated by the emphysema of the lungs. The case was an example of neuropathic dropsy.

The writer notes the phlebitis obliterans of the hepatic vein described by Chiari. In a case of excessive ascites and enlargement of the liver, followed by œdema of the lower extremities, death took place from œdema of the lungs. The autopsy showed organised thrombi in the hepatic veins. Several branches of it in the substance of the liver were blocked by thrombus formation and growth of the intima. Possibly in this case, too, the primary lesion lay in the splanchnics.

OPERATIVE TREATMENT OF CIRRHOSIS OF THE LIVER.

The *D. Med. Zeit.*, October 2nd, contains a reference to this subject. One of the most important sequelæ of this disease is ascites. Cirrhotics ultimately fall victims to stasis of the portal system, and with permanent relief of the chief symptom the whole course of the disease is so favourably influenced that operative treatment of cirrhosis of the liver will not be an incorrect expression. The author, Prof. Lanz, says that the idea of setting up a collateral portal circulation was conceived almost simultaneously by Drummond in England and Prof. Talma, of Utrecht. A number of cases of cirrhosis of the liver had been observed in which there was no ascites, and this fact gave an indication in the direction of the artificial fresh side-tracks for the blood of the portal vein. To this end the operation of fixing the omentum to the abdominal wall was proposed, and this procedure, the so-called Talma operation, has been performed about sixty times with about forty recoveries.

The writer has advised this operation in five cases; two have had it performed, of the remaining three cases two have died. In one case in which the operation was performed the result was extraordinarily favourable, and the prompt improvement after the operation was beyond all expectation. In the second case the result is still doubtful. The operation itself is a very harmless one, and only dangerous when cardiac power has fallen too low. In such cases the operation should be performed under cocaine or injection of Schleich's solution.

In exceptional cases convulsions have been observed after operation. Experiments on animals have shown that when nourishment was entirely vegetarian such attacks never come on. Flesh foods should therefore be forbidden when such an operation is to be undertaken. In cases in which the outlook is so unfavourable, such as in ascites from cirrhosis, such an operation is quite justifiable, and it should be carried out before the patient's powers are too far reduced.

CARBONIC ACID AND DIGESTION.

In the *D. Arch. f. Kl. Med.* Prof. Fr. Penzolt discusses the action of carbonic acid during digestion. The investigation showed no considerable influence, but an undoubted improvement was observed in several directions. The secretion of gastric juice begins earlier and attains an average above the normal. If it fails earlier this is because digestion is completed more quickly. This was proved. Effervescing drinks are also useful in promoting diuresis in a large number of diseases. In diseases of the stomach with ulceration and stenosis of the pylorus such drinks are contraindicated on account of their property of inflating the stomach with gas. In deficiency of acid and want of tone, in view of the increased secretion and greater rapidity of digestion, inflation will not be so dangerous, and a trial of half a litre of effervescing water may be permitted after a meal.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, October 18th, 1902.

"MAKROCYTASE."

METSCHNIKOFF recently described a hæmolytic substance which he had isolated in the laboratory from an organic substance, the activity whereof in provoking hæmolysis was as potent as any serum yet discovered. To this substance he has given the name of "Makrocytase."

According to Metschnikoff and his followers, more particularly Tarassevitch, this active principle is identical with that found in phagocytes, or makrophagen, from which the new term has been derived, while mikrophagen is applied to the bacteriolytic property of serum obtained from the polynuclear leucocytes. The hæmolytic property of cell extracts was first observed by Shibayama and Klein, who suggested a relationship with the hæmolytic agency found in sera. A later view is promulgated by Korschan and Morganroth, who by recent experiments have proved by the investigation of many organic extracts, that the so-called "makrocytase" is identical with the active principle hæmolysin.

With these experiments before them Donath and Landsteiner, in Weichselbaum's laboratory, attempted to explain by injections of cells the anticomplementary sera. Their object was to discover whether the bactericidal material in the leucocyte extract was of the same nature as that met with in the sera; but the results of their labours were the same as those of Gruber, viz., that the active principles are quite different. They also established an affinity between "makrocytase" and hæmolysin, based on the absence of hæmolytic action in an extract of polynuclear leucocytes when applied to he serum. This "makrocytase" of Metschnikoff comprises both makrophagen and the active principle of polynuclear leucocyte extracts. They also found that the organic extract was active, even when the serum failed; but their temperatures of activity were different. They also found, like Klein, that pancreas extract had a hæmolytic action on the blood corpuscles of a similar animal to the one from which the extract had been obtained. To this peculiarity they think is to be attributed the diversity of results hitherto obtained.

Another point to be observed in their experiments was the fact that the hæmolytic extractive could not be obtained from that part of the organ in which the operations of the phagocytes were most commonly performed; for example, an extract of the liver where the endothelium of capillaries has the property of destroying the red blood corpuscles has been found to be quite inert.

Morgenroth and Korschan are of opinion that the hæmolytic extractive owes its action to a sort of autohæmolysis of the organ, analogous to that of a bactericide. Donath and Landstein hold that Conradi's experiments support this view, since extracts of different organs obtained by pressure when boiled for half an hour still possessed the same hæmolytic action.

HÆMAGLUTINATION.

Landsteiner gave a number of examples taken from his own experiments with blood clots and immunising serums to show how capricious they were in their action. If blood corpuscles are washed out of a clot coagulated either normally or with immune serum, by means of a physiological solution of NaCl, until little or no agglutination takes place, they will, after digesting with the same solution of sodium chloride at a temperature of 50° C, regain an intense agglutinating power. Normal serum agglutinated corpuscles when digested often lose this power with different sorts of blood.

Human milk also contains an agglutinating agent for the blood corpuscles of animals. In some cases the milk will agglutinate the subject's own blood—auto-agglutination.

The Operating Theatres.

MIDDLESEX HOSPITAL.

Cystic Disease of Breast.—Mr. Andrew Clark operated on a woman, æt. 45, who had been admitted complaining of pain and swelling of the left breast. On investigation this proved to be cystic disease involving the greater part of the organ. There was a large definite cyst above the nipple, and two smaller ones below. The patient had stated that she had been in the hospital two years previously, when her other breast had been removed for a similar condition. From that time, as before, she had enjoyed good health, and it was not until the middle of the past summer that she noticed anything wrong with the left breast. The breast was excised in the usual way by a vertical elliptical incision. The edges of the wound were brought together without any tension, and covered with cyanide gauze, which was strapped on, the arm being tied to the side by a broad sling. Mr. Clark said that this was a case in which the diagnosis was obvious, and it was curious that the second breast should assume the same condition as the other which had been removed two years ago. It might be suggested, he said, that in cystic disease it was unnecessary to perform so radical an operation, and that excision of the cyst ought to be enough to cure the affection, yet in the operation on the first breast excision of the cyst was first practised, but another one was found which had not been detected before the first incision; as soon as this was removed two others were discovered, and under these circumstances it was decided to remove the whole of the mamma. In this several smaller cysts were found. The second breast being apparently in a similar condition, the patient had requested that the breast itself might be removed, and he had been quite willing to concur in her desire; the sequel showed how right it was to do so.

Thiersch Grafting after Removal of the Breast.—The same surgeon also had brought into the theatre a woman whose breast he had removed a fortnight before on account of a small scirrhus which occupied the upper segment of the organ, and involved a considerable area of skin, necessitating the removal of so much tissue that it was found impossible to bring the edges together. There was now a healthy granulating wound, about the size of the back of a man's hand. Mr. Clark said that, although in time the granulations would have all skinned over, the little operation of transplanting the epidermis from the arm to the raw surface of the breast not only would expedite cicatrisation, but would produce a firmer and sounder cicatrix. In doing this operation he pointed out that the chief thing to bear in mind was that any weak granulations should be scraped or rubbed off previous to the transference of the new cuticle. There was sometimes, he remarked, a little difficulty in shaving off the graft from the arm, but the parts should be wetted with carbolic lotion, 1 in 40, and a sharp, long amputating knife used, which would be found more convenient than a razor. Mr Clark then proceed to carry out the operation on these lines, and covered the entire granulating surface. The whole of the area of operation was afterwards covered with perforated tin foil, over which gauze was placed; the tin foil, he said, serves to prevent the gauze injuring the delicate grafts when the part is dressed.

GREAT NORTHERN HOSPITAL.

Nephrectomy Eighteen Months after Removal of Calculi.—Mr. Peyton Beale operated on a woman whose history was as follows: In August, 1901, a number of calculi were removed from her left kidney; this operation being described in The Medical Press and Circular "Operating Theatres," August 28th, 1901. Since that time she had remained in fairly good health, but the sinus leading to the diseased kidney had opened up early in the present year. No operation could be performed as she was six months pregnant, and, having a contracted pelvis, she was admitted under Dr. Blacker, who induced labour. After this she suffered a good deal from cystitis, but was not well enough to undergo an operation for nephrectomy, so was sent to a convalescent home. She was re-admitted to the hospital a week before the present time, and an operation was performed as follows: The scar in the left lumbar region was incised for a space of four inches; the right forefinger was then inserted and the edges of what was left of the kidney were without much difficulty separated from the scar; the remains of the kidney were then gradually freed all round, and cautiously pulled up out of the wound. The ureter was ligatured and two ligatures were placed, one on the renal artery and one on the renal veins; the kidney was then removed. There was very little hæmorrhage, and the large cavity was washed out with hot sterile lotion and stuffed with cyanide gauze. The interesting points about the kidney, Mr. Beale said, were: it measured about six inches long by four inches broad, and was found to contain about half a dozen calculi, two of them being as large as broad beans; it was also remarkable how much kidney secreting substance there was; for at the previous operation the kidney appeared to be simply a thin walled sac, quite packed with calculi, all of which at that time had been carefully removed, as previously reported. This, Mr. Beale said, seemed to show that new secreting kidney substance even in considerable quantities could be formed in connection with a kidney which a year previously had been found to be merely a sac, and also that calculi of considerable size could also be produced within a year during the growth of that new kidney substance. Mr. Beale again remarked upon the advisability of dealing with these cases in two operations, for in his experience the operation for removal of the remains of the kidney was in nearly all cases necessary subsequently to the removal of so many calculi: to combine both operations at the same time constituted, he thought, a very severe operation, and one which caused a great amount of shock: moreover, it was a very much more easy matter to remove the remains of a kidney some months after clearing out the calculi. He believed that this had to be done in practically all cases in which at the first operation the kidney was found to resemble a sac full of calculi with but little secreting substance. He had not before met with a case in which so much new secreting substance had been found as in the present one.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 22, 1902.

THE ELIMINATION OF THE DRUNKARD.

Drunkenness, at least in polite society, fortunately now spells disgrace. The inebriate is at last recognised to be an enemy of the State. Alcoholism is a morbid condition threatening human progress. The abuse of alcohol furnishes subject matter for the thoughtful consideration of all sorts and conditions of men. The evil is all too evident; the remedy is yet unfound. Concerning the pathology of drunkenness we know much, but concerning its treatment we differ widely. The inebriate is ever with us. In prehistoric times he was not unknown: according to many observers he still shows no tendency to "die out," and for all we know inebriety will long continue as an evidence of human frailty. And yet constant efforts are being made to "reform" or to "eliminate" this, as many would reckon, "unfit" element. Some time since Mr. Archdall Reid, in his ingenious work on "Alcoholism," sought to indicate what he considered was the only sure "natural" method of eliminating the drunkard. He viewed the "drink craving" as a specific, simple inheritance. Races which have been in possession of alcoholic drinks the longest, he contended, are the least drunken, in consequence of the elimination of those whose "drink craving" was too strong for them. He sought to apply the known facts regarding "predisposition" and "immunity" to this question of drunkenness. Mr. Reid's theories, although ingenious and suggestive, present many weak places, and Mr. Wells, in his valuable essay on "The Problem of the Birth Supply," in the current number of *The Fortnightly*, points out some of the holes. He shows that there is no clear reason for recognising any specific and simple "drink craving" any more than for believing in an inherited tea craving or an inherited morphia craving. Mr. Reid's views disregard the true nature of that which we speak of as "habits." People vary immensely in their power of acquiring habits, and also in the strength and fixity of the habits they acquire. Many causes and many temperaments go to the making of drunkards. Mr. Reid seems to neglect the fact that the nations which have had fermented drinks the longest are those which have been civilised the longest. The passage of a people from a condition of agricultural dispersal to a more organised civilisation means a very extreme change in the conditions of survival, of which the increasing intensity of temptation to alcoholic excess is only one aspect. People who have dwelt for many generations in towns are not only more temperate and less explosive in the grosser indulgences, but more urbane altogether. The great prevalence of drunkenness among the upper classes two centuries ago can hardly have been bred out in the intervening six or seven generations, and Mr. Reid's theory is not strengthened by the fact that drunkenness is on the increase in France. As many will remember, Mr. Reid's suggestion for securing the exit of the "unfit" drunkard was grotesque and ludicrous. Mr. Wells, as we think very rightly, shows that until we possess a far more subtle and thorough analysis of the drunkard's physique and mind than we have at present, we have no justification whatever in artificial intervention to increase whatever eliminatory process may at present be going on in this respect. And even if there be such a specific weakness as "the drink craving," it is possible, as Mr. Wells suggests, that it has a period of maximum intensity, and if that should be only a brief phase in development, as at adolescence, it might turn out to be much more to the advantage of humanity to contrive protective legislation over the dangerous years. Mr. Runciman, in his "Ethics of Drink," shows that, instead of inebriety being a failing of feeble men, it has proved in only too many instances a calamity to noble minds; and in proof thereof we have only to think of the sad experiences of such men as Turner, Cellini, Bulwer Lytton, George Morland, Keats, Charles Lamb, and a host of others who have helped us in the upward climb. Dr. Shadwell, in his recently published work on "Drink, Temperance, and Legislation," says, "The fundamental fact at the bottom of the drink question is the physiological action of alcoholic liquors on the animal organism." This is undoubtedly so, and if we are to arrive at a satisfactory conclusion regarding the pathology of drunkenness, it will be by taking a wide outlook, and probing deeply into the subject after the manner which Mr. Wells has set in his peculiarly attractive study.

UNQUALIFIED MEDICAL PRACTICE.

The startling case of alleged personation of a medical firm by an unqualified man, who is said to have carried on practice in London for some time past, furnishes no little food for reflection. At present the accused labours under the serious charges of perjury and manslaughter, so that we have no intention whatever of discussing his position. At the same time the bare possibility of such an occurrence raises questions of the utmost importance as regards the interests of the public no less than that of the medical profession. The prosecution in the present instance has arisen from the disclosures at a coroner's inquiry, at which the accused received a fee for medical evidence given in the sworn capacity of a registered practitioner. Under existing Acts, as everybody knows, it is not compulsory for duly qualified men to enrol their names on the *Medical Register*. Under this most unsatisfactory arrangement many medical men are qualified but not registered. There are certain disqualifications attached to unregistered practitioners, some of which, there is little doubt, are systematically evaded. Poor-law and other official appointments cannot legally be held by unregistered medical men, and it would repay many unsuccessful candidates for such posts to inquire as to the registration status of the gentleman appointed. It is to be feared that many unregistered medical men are permitted to give evidence in coroners' and other courts, notably magisterial, owing to the laxity of court officials, who could in most instances settle the matter forthwith by a reference to the published *Register*. These points seem to remind us of the fact that only one phase of unqualified practice is affected thereby, namely, those pretenders who are unwise enough to assume the title of doctor. By the unwisdom of the Legislature and the inefficiency of the Medical Acts all other forms of quackery, however gross, fraudulent and harmful, are allowed to go scot free. It is clear that unqualified medical practice constitutes a danger to the public, whether carried on under the guise of a medical title or not, as this simple point summarises the whole position with regard to the future regulation of unqualified medical practice. In law it is a punishable offence to conduct legal business quite apart from the assumption or otherwise on the part of the offender of any legal qualification. A similar provision in medicine would bring the whole range of unqualified practice within the control of the State. If the General Medical Council could be induced to address themselves to the protection of the public and the medical profession they would find the crucial points to be compulsory registration and the extension of punitive powers to all unqualified practitioners. As matters stand the strength of the nation is being sapped and undermined by wholesale quackery of the cruellest and basest possible description, while the members of an honourable profession are forced to the wall by a competition that is disastrous not less to themselves as a class than to the community at large.

CONSUMPTION IN IRELAND.

The population of Ireland has been steadily falling for over fifty years, and yet the death-rate from tuberculous disease of the lungs has gradually risen. The phenomenon is a somewhat strange one; the people are better clad, better housed, and better fed than formerly. We know more of tubercle and its lethal effects, and are better able to ward off the disease and to treat it when it does come. But the increase in the number of cases is alarming; death from tuberculous disease is becoming the most common form of death in the young, adults, and in those of middle life. The explanation lies in the altered mode of life of our people. The same cause is producing the same results in almost every other civilised country. Formerly the greater number of our people dwelt in the country, followed agriculture as an employment, lived in the open air, fed on milk, potatoes and maize, with an occasional dinner of home-cured bacon. The houses, wretched as dwellings, were still well-ventilated. To-day the youth of the country find the road to the nearest large city, and enters a factory or chains himself to an office desk. He marries in the city, and rears his family in surroundings wholly unlike those in which he was reared. His food is changed for the worse, and the draughty hovel purified by Atlantic breezes gave a lung power that his city reared family can never hope to possess. Living in stuffy ill-ventilated rooms, sleeping and eating in them, feeding on tea and bread, they succumb to the tubercle bacillus and propagate it in the dust-dried sputum which permeates the air of every tenement-house in Dublin. The same story comes from Australia, Argentina, Mexico and

Russia. We are aware of the fact that an enlightened enforcement of sanitary laws in large English cities, notably Manchester and Liverpool, has diminished the percentage of the death-rate from consumption in those cities. The sanitary laws enforced are those that are best calculated to restore conditions approaching to life in the country. The fearful mortality of consumption practically dates from the introduction of steam as a motor power. To utilise it economically it became necessary to congregate hands in great, many-storied factories. To check this mortality it is necessary to bring the people away from towns and factories, from filthy tenement houses, musty, disease-laden sleeping-rooms, and ill-ventilated offices, to the pure air of the country. And this has been made possible of accomplishment by the introduction of electricity. In Ballyshannon, Killaloe, Athlone, indeed in every county in Ireland, electricity can be generated by water power and distributed to the homes of the workers without loss. The social revolution which the changes from cities to the country would entail will be great, but some day it must be accomplished.

Notes on Current Topics.

Midwifery Instruction in Obstetrics.

We referred briefly last week to the opinion expressed by a coroner's jury deprecating the practice of sending students to attend midwifery cases, not unfrequently to the detriment of the patient. The practice, we have no hesitation in asserting, is one fraught with risk to the parturient poor without any compensatory advantage in regard to the student. Midwifery is an art which requires to be taught, and no provision is made for the practical instruction of the student beyond the little knowledge he picks up as best he may in attendance on such cases. The proper place for such instruction is the lying-in hospital, and elsewhere than in our own country this is the only place where such instruction is imparted, although preliminary training is given on mannikins at the school, a method of training which is woefully neglected in this country. The difficulty has arisen from the fact that lying-in hospitals in this country are independent institutions, not affiliated to any school of medicine, attendance at which is not compulsory on students, and entails the payment of extra fees which few among them are disposed to pay. No progress can be effected in the direction of remedying an admitted lapsus in medical education until arrangements have been made for the attendance of students in the wards of a lying-in hospital where proper instruction is imparted by the medical officers. Monthly nurses are thus trained systematically, and it is surely vastly more important that medical students should be afforded a similar opportunity for the acquisition of the necessary technical training. When such arrangements have been made it will probably not be difficult to persuade the General Medical Council to make attendance at a lying-in hospital a compulsory feature of the curriculum. At present the Council has difficulty in enforcing even the modicum of instruction actually required.

The Administration of the Vaccination Act.

It has been urged from various quarters that the time has arrived for a transference of the powers in respect of the administration of the Vaccination Act, at present invested in boards of guardians, to some other authority better adapted for the purpose and less amenable to passing gusts of popular feeling. Experience has shown clearly enough that boards of guardians are not to be trusted with the enforcement of this important law, and the mechanism by which pressure can be brought to bear on recalcitrant boards is so complicated, not to say clumsy, that in many parts of the country the law has for years been virtually allowed to fall into abeyance. Before any move can be made in the direction of remedying the present anomalous and unsatisfactory state of affairs, it behoves us to decide in principle what other body would offer a better prospect of the law being enforced, and obviously the duty is one which falls within the domain of the sanitary authority. Vaccination is distinctly a department of preventive medicine, to which prophylactic and sanitary measures also belong, and there is no obvious reason why they should not all be administered by the same officials. This plan would have the merit of removing the administration of the Vaccination Act from local, though not from popular, control, and vaccination is certainly a measure of imperial rather than local concern. The only alternative which suggests itself is the appointment of a special administrative officer holding his authority directly from the Local Government Board, who would superintend public vaccinations and initiate prosecutions when required. The objection to the latter alternative is that it would probably entail additional expense, but, after all, any reasonable increase of expenditure would be more than compensated by the more uniform enforcement of the operation.

Potassium Chlorate in Habitual Death of the Fœtus.

The internal administration of chlorate of potassium, which was first recommended by Sir James Y. Simpson in cases of habitual death of the fœtus in the later months of pregnancy, in non-syphilitic cases, has found another advocate in the person of Dr. Robert Jardine, whose experience and opinion of the value of the drug are favourable to its use. Among the cases he relates one was of special interest. Dr. Jardine attended a patient in her fifth confinement within six years of her first one. Except that the labour was a lingering one, there was nothing abnormal about it; the child was healthy, and is still alive. Within a year she had a miscarriage. Within twelve months she had a premature labour with a putrid fœtus, and narrowly escaped death from sepsis. When she next became pregnant Dr. Jardine put her upon potassium chlorate and she went to full time. The child was quite healthy and is still alive. In her next pregnancy she did not take the chlorate, and the result was a miscarriage. She soon became pregnant again, and on taking the chlorate she went to full time and was delivered of a healthy child, though she suffered during labour from hæmorrhage and what was apparently a pulmonary embolism. In her next pregnancy the patient took the chlorate again and went to full time. Since then, she has had at least two miscarriages when she was not taking the chlorate. Dr. Jardine does not offer any explanation as to the manner in which the drug acts, save to say that he considers it to have a beneficial effect on the endometrium. He dissents from Sir J. Y. Simpson's explanation that it provides more oxygen for a damaged placenta to convey to the fœtal circulation. Whatever may be the *rationale* of the action of the drug, if it produces the effect claimed for it, and if, as he asserts, its use is free from danger, it is certainly worthy of a trial in obviously non-syphilitic cases. The usual treatment for this class of case, *i.e.*, the induction of abortion, has yielded such unsatisfactory results that any more promising line of treatment will be welcomed.

The Relation of Trees to Cancer.

A French medical man, M. Dor, has recently made an interesting report on the relations of cancer to locality, occupation, and vegetation in France, a work in which he has been helped by subsidiary reports received from other medical men throughout the country. His observations and those of his medical friends are both interesting from a clinical point of view and of great importance as bearing on the question of causation. Of the many reports we can do no more than refer to one of seventy-three cases of cancer in the practice of one physician, and of all these sixty-seven occurred in isolated farmhouses on the borders of woods, and six only occurred in villages. In the country districts the inhabitants look on the disease as of vegetable origin, and believe that it is propagated in a manner similar to that in which actinomycetes is conveyed by fodder; and in support of this popular view is the fact of its frequency among those whose occupation necessitates their living in the vicinity of forests. M. Dor draws attention to the pathological growths of the bark of the fir tree, and points out how closely they simulate malignant growths in the human being, and the effects of excision in the vegetable and animal kingdom. Trees suffering from the growth have been found in the vicinity of cases in the human being, and in one case the growth of an epithelioma followed on the blow of a firwood stick on the lip. M. Fiessinger asks: May not these vegetable parasites of tree cancer be analogous to the cancer parasite of M. Metschnikoff? As might be expected, the revival of this theory by M. Dor, for it is not altogether a new one, has excited interest afresh on the subject, and Bra, Pouchet, Chevalier, and others have been experimenting with mammals and trees, inoculating from the vegetable to the animal kingdom, and from the animal to the vegetable, with, they claim, success. The experiments cannot be other than helpful in the study of the question; nevertheless, we are unable to accept them as proving that cancer is of vegetable origin. In following the results of their laboratory work, and in drawing conclusions from the facts submitted to them, we fear the distinguished pathologists overlooked the fact than cancer is essentially a disease of civilised life. It is practically unknown among savages. The arboreal pigmies of Equatorial Africa know it not; the North American Indian is free from it; the Canadian woodman, the Norwegian pine-feller, the mahogany-cutters of Honduras, the rubber-tappers of the upper reaches of the Congo, the hacienda dwellers of the La Plata are practically exempt from it. Neither Humboldt nor Livingstone record a case, though these travellers travelled the most wooded countries of the world. Of course, it may be fairly said that wild trees are not so subject to disease as cultivated ones, and, further, that the timber of tropical forests is not so prone to the disease as are the cultivated trees on the limits of the temperate zone. We acknowledge this, but still we doubt that the theory of a vegetable origin will prove to be tenable.

Bearding the Barber.

Mere man, when stationed beneath the blade of the barber, feels himself the victim of circumstances. As long as Nature strives to assert her right to maintain hirsute appendages and fashion denies their continuance, the barber will live and flourish. When placed in the operating chair the time for argument, explanation, and restriction is passed. And yet the profession of barber is badly in need of regulation and direction. It has been shown conclusively that the apparatus of the barber is capable of conveying disease, and in many instances the barber himself, as well as his shop, stands in need of reform as regards sanitary conditions. We venture to think that public opinion should be educated on this matter. In America the subject has been dealt with. The San Francisco Board of Health have recently adopted severe restrictions and regulations for the sanitary control of barbers' shops. The hygienic reasonableness of many of the rules cannot be denied. Absolute cleanliness must be maintained. Mugs and shaving brushes are to be sterilised by immersion in boiling water or formalin solution. Razors are to be wiped with 95 per cent. alcohol. "Sanitary brushes" must be employed, and are to be sterilised by being placed in boiling water or dipping in formalin solution. Combs are to be treated in a like manner. Razor strops are to be kept clean. A clean towel must be provided for every customer. The prevalent custom of blowing away hairs must be discarded. Attention must be devoted to the cleansing of the operator's hands, and particularly finger nails. Powder puffs are to be prohibited, and the use of sponges discarded. The wash-basins, pipes, and drains must be in perfect sanitary condition. All instruments must be kept absolutely clean, and, where possible, disinfected. Barbers must never attempt to treat skin diseases. We could wish that like regulations could be enforced in this country. Many of the barbers' shops which we have visited in London and various parts of the country seem to be in the hands of foreigners whose ideas regarding cleanliness and hygienic requirements are conspicuous by their absence.

Malta Fever.

An item of clinical medicine of Oriental—or quasi-Oriental—origin consists in the recent recognition of the wide-spread distribution of an undulating type of fever—usually known as Malta fever—the notching of the temperature chart in which is not sufficiently deep to entitle it to the descriptive epithet of "intermittent." In the United States, isolated cases have from time to time been recognised during the past few years; and, since the development of the policy of Imperialism, with its collateral complications and their various sequelæ, a greater proportional number have appeared in the persons of soldiers recently returned from the Philippine Islands. It is an interesting and remarkable fact that in India the existence of this disease, whether of imported origin or of sporadic indigenous growth, has never been established, although ample and favourable opportunities for its introduction have undeniably existed.

The Medical Profession and the Army.

The address delivered last week by Sir William Taylor, Director-General of the Army Medical Service, at University College, directs attention to various points of interest in connection with the service. He admits that the medical department is much undermanned, and we gather that he holds the view that its members are never likely to be in a position to adequately fulfil the duties incumbent upon them under the strain of a great war. On the other hand, the number of medical men who study in time of peace the problems that have to be considered in time of war is small, so that there exists no real reserve available for emergencies. One way out of the difficulty, he suggests, would be for each medical school, or combination of schools, to equip, maintain, and administer units in time of peace which could proceed to the field in a state of complete efficiency. The idea is ingenious, but we doubt its practicability. Medical students have enough to do as it is in preparing for examinations, and once they have qualified, their energies are likely to be absorbed in the "struggle for life." We do not see any opportunity for them to acquire the technical knowledge which is to fit them for medical service in the Army in the absence of any intention on their part of taking up the career as an objective. Would it not be practicable for the State to control the recruitment of surgeons to Volunteer and Militia regiments under conditions which would secure efficiency and render their services available in case of need. Another alternative would be to distribute civilian appointments in connection with the Army exclusively to young practitioners who would undertake to respond to the call in the event of need. The matter must be dealt with on a purely business basis. Patriotism may, perhaps, be trusted to a certain extent in times of stress, but it is a negligible quantity in the piping times of peace when men's minds are concentrated on matters afferent to their immediate needs.

Ignorance No Excuse.

Lest the Italian manufacturers and vendors of ice creams and similar alimentary delicacies, many of whom are passably ignorant of the English language, should fail to become acquainted with the new sanitary regulations which bear on their calling, Dr. Collingridge, Medical Officer of Health for the City of London, has caused notices in the Italian language to be printed, calling attention to the new requirements which come into force on November 1st. In spite of this thoughtful act we confidently anticipate that the sanitary police will have plenty of work on hand in persuading them, with the help of a magistrate, to conform to these very necessary regulations.

Carbon Monoxide Asphyxia.

In view of the extremely small proportion of carbon monoxide required to cause death—one part in two thousand—it is surprising that disasters from this cause are not of more frequent occurrence than they are. In this country, where the use of movable stoves is almost unknown, such accidents are almost invariably due to imperfect provision for the escape of the products of combustion generated by apparatus for heating water for baths. The careless way in which floors are laid and the inaccurate fitting of sash windows, as a rule, allow of such free ventilation that under ordinary circumstances nothing more than temporary inconvenience is caused by leakage. In France the impermeable parquet-floor and the hermetic sealing of windows and doors render even small quantities of this deadly gas highly lethal—witness the regrettable death of M. Zola. The danger is nevertheless omnipresent. An accidental blockage of the chimney by soot or fallen bricks may prevent the escape of the products of combustion, or these may percolate through fissures in the party-wall and find their way into adjacent bedrooms. Certain winds, again, may, and often do, determine down currents of air in the chimney, though in countries where coal is cheap attention is usually attracted by an inrush of irritating smoke. Lastly, people are but too apt to forget that a fire requires an adequate supply of air, and if all inlets are carefully blocked to keep out the cold air a certain proportion of the contaminated air which ought normally to go up the chimney is thrown back into the room. Even when not fatal the habitual inhalation of even minute quantities of this gas is productive of grave mischief, especially in the production of intense anæmia not amenable to the usual medicinal measures, since it is due to the virtual destruction of large numbers of red corpuscles which cannot readily be regenerated or replaced.

The Polished Floor.

By slow degrees it may be hoped that the conclusions of sanitary science may be applied to the environment of dwelling-houses. One of the great advances in modern times has been in the adoption of impermeable surfaces. The ordinary wooden floor is a snare and an abomination, and when the boards are left bare and washed from time to time with soap and water it rapidly becomes a danger to health. The boarding rots and its interstices fill with decomposable and decomposing matter, while the emanations given off during the process of drying lays the seed of many a lung trouble, especially among children. On the other hand, when the boards are carpeted the dust that lodges thereon, even in the best-kept household, is raised in invisible clouds at every footstep. Dust, carpets, and disease are inseparably associated in the mind of the modern sanitarian. A far better plan is to have a floor prepared either with a varnish stain or with a wax polish. The surface is then readily swept or rubbed down with a duster, and can be protected, if necessary, by carefully disposed linoleum mats; or by a few small, closely-woven rugs or mats. In the bedroom the polished floor is *facile princeps.*

Short Service in the Navy Medical Service.

We have received a copy of the recently-established regulations for the admission of surgeons for temporary service in the Royal Navy, according to which duly qualified men not over forty years of age, in good health, will be admitted to the Service for a period of six months certain and a qualified liability to serve for five years. At any time after the six months' service, however, they may be given two months' notice (or its equivalent in pay) that their services are no longer required. The pay will be at the rate of 22s. a day, or £410 a year, with half-pay for sickness, and leave at the rate of 10s. a day. They will be awarded pensions for wounds, and pensions and gratuities will be paid to widows, young children, widowed mothers, and orphan sisters of surgeons killed or wounded *in action*, but, of course, preference will be given to unmarried candidates. Injury, disease, or death occurring in the ordinary course of events will not entitle to either pension or gratuity. Provision is made for voluntary resignation, subject to the convenience of the Service, but in that case the two months' pay on discharge will not be accorded. The adoption of the short-service system in the Navy is tantamount to an admission of difficulty in recruiting the medical staff, and with one or two modifications may prove successful in attaining the object in view. It is, however, a drawback that those accepting temporary employment are liable to discharge at any period after the initial six months, with two months' pay by way of solatium, especially as no provision is made for their discharge at a home station. There is also the fact that if the officer contracts disease or injury in the ordinary duties of his post, no matter under what circumstances, he will have no claim to a pension or gratuity. Moreover, no facilities are offered for a surgeon on temporary engagement to join the regular staff should he be so minded. The system appears worthy of trial, but we strongly recommend intending candidates to weigh the advantages and disadvantages well before taking the leap.

Adenoids and Nocturnal Incontinence.

The classic treatises on diseases of childhood make little or no mention of the part played by adenoids in causing nocturnal incontinence of urine in children. Henoch, in the long list of pathological conditions that he gives of exciting causes does not mention them. But he has the courage to confess that "Unfortunately, you will not in the majority of cases succeed in finding any of the abnormal conditions mentioned, nor even if they are found, will you manage to cure the enuresis by treating them." The correlation between adenoids and nocturnal incontinence attracted the attention of Major in 1885, and Baumgarten soon afterwards cured two intractable cases by the removal of adenoids. But these cases were too few to attract notice, and it was not until Freyberger published his eighty-six cases, and Fischer published his investigations on the effects of removal of adenoids in children, in which he found that in forty-three cases the operation caused the cessation of the incontinence, in seventy-three cases greatly benefited the patients, and in five produced no effect, that Etievant's theory that the deficient oxidation of the blood in children, whether brought about by adenoids or other nasal obstructions, produced anæmia, headache, nightmare, and by a reflex action nocturnal incontinence. The urine in such cases is passed in a stream, and only during sleep, or when the child is half awake. Here, in fact, there seems to be a reflex irritation of the detruser, the action of which is all the stronger because the influence of the will on the sphincter is in abeyance during sleep. Fischer is confirmed in his opinion that the exciting cause of the incontinence is due to insufficient aeration of the blood producing nightmare which affects the renal secretion and the bladder, by noticing that in some cases the removal of the adenoids produced no good results, the nasal respiratory tract being in part occluded by polypoids of the inferior turbinates, the removal of which was immediately followed by a cessation of the nocturnal incontinence. The effect does not, however, always follow so quickly on the operation; in Etievant's cases fifteen days elapsed before the desired result was obtained. In this, as in most cases in which the art of medicine has advanced, the progress resulted from accurate observation of the phenomena of the disease, and corrected induction from the observed facts. How many physicians must have noticed children breathing through the mouth during sleep before Major discovered the correlation between imperfect oxydation of the blood and nocturnal incontinence.

A Case of Dercum's Disease.

An additional case of Dercum's disease, or *adiposis dolorosa*, has been added to the twenty-five which, according to Professor Dercum, have been described up to the present time. This case has been recorded by Dr. Bochroch, at the Philadelphia Medical Association. The patient, who was aged fifty-six and married, had increased in weight from 100 lbs. to 236 lbs. She presented the four cardinal symptoms which have been noted by Vitaut in this condition—viz., enlargements in various parts of the body due to the deposit of fat, pain, neurasthenia, and various psychic symptoms, which, in her case, assumed the form of impairment of memory and mental hebetude. There was a fatty deposit the size of an egg under the chin, masses of pendulous putty-like fat near the axillary regions, and over the hips and abdominal region the fat hung in folds. The slightest touch on any of these areas caused pain. Dr. Bochroch is inclined to consider that in all probability there are many cases of this condition which escape recognition, as the case he records was under observation in a public clinic for over a year without being recognised. The pathology of Dercum's disease is still quite obscure, and the present case does not appear to have given any assistance towards its elucidation. Burney Yeo, writing in the "Encyclopædia Medica," suggests that the thyroid gland plays some mysterious part in its causation, but does not draw any conclusion as to treatment.

The New President of the Royal College of Physicians of Ireland.

The election of Professor A. V. Macan to the Presidency of the Royal College of Physicians of Ireland will be hailed with satisfaction throughout the obstetrical and gynæcological world in general, of which he has been for many years one of the most prominent members. Professor Macan graduated in the University of Dublin in 1868. In 1877 he was elected a Fellow of the College, of which he is now the titular head. In 1882 he became Master of the well-known Rotunda Hospital, where he firmly established his reputation as one of the foremost gynæcologists of the day. On his leaving the Rotunda Hospital he was appointed to the chair of King's Professor of Midwifery in the School of Physic of Trinity College, Dublin, a post which he still holds. He is an ex-President of the British Gynæcological Society and of the Obstetrical Section of the Academy of Medicine in Ireland, a post to which he has been twice elected, and was also honorary president of the Obstetrical Section of the International Medical Congress held at Berlin in 1890. Though not a prolific writer, the new President has contributed many communications of extreme importance to medical literature, and was notably responsible for the introduction into these countries of rational ideas on the subjects of uterine displacements. It is now some years since the post of president of the college was held by an obstetrician and gynæcologist, although many such have been conspicuous presidents in the past. To their list the name of the newly-elected president is a worthy addition, and one on which we can congratulate the college.

The High-Frequency Treatment of Cancer.

Although the ultimate origin of cancer has not yet been brought within the grasp of medical science there are nevertheless signs of the times that are most gratifying in their nature. Electricity appears to be advancing its claims to a considerable extent as a valuable remedial or even curative agency. The older methods of electrical treatment had been practically discarded in the treatment of malignant disease when the Röntgen rays and the high-frequency current put in an appearance on the field of action. Results from both methods have been so encouraging as to justify the highest expectation with regard to their future application in cancer. The Röntgen rays act chiefly on surface growths, and are especially valuable in post-operative recurrent nodules. The high-frequency current is most suitable for cancer of bladder, rectum, uterus, throat and nasal cavity. In suitable cases it restores appetite and sleep, while the patient puts on flesh, while the growth either diminishes in size or altogether disappears. Where no further operation can be attempted, or where the case is for other reasons inoperable, the high frequency current deserves a trial.

The Contagiousness of Pneumonia.

Although pneumonia is one of the oldest known diseases, there are many points in its etiology which remain obscure. The explanation may possibly be found in the fact that it is not a distinct morbid entity but is merely a collateral consequence or a sequel of many complex pathological states. It is very generally believed to owe its origin to a chill; but, although this may be one factor in its production, it cannot be the only, or even the principal, one. Nor can the pneumococcus be the essential factor in all forms of pneumonia, since its presence cannot be demonstrated. Then, too, there is a particular variety of the disease, which appears to be readily capable of transmission to persons exposed to infection, a quality which is by no means characteristic of all cases in which the pneumococcus is found. With the progress of knowledge it may ultimately be possible to differentiate the various forms of pneumonia one from another by the aid of bacteriology, although clinically they are indistinguishable. In this respect it is highly desirable to distinguish between active and passive pneumonia, the first being secondary to some deeply-seated organic disturbance; while the latter is, in the great majority of instances, probably the direct outcome of infection.

Local Bodies and the Adulteration Acts.

THE annual loss from food adulteration inflicted on the population of the United Kingdom must annually reach an enormous aggregate sum. In the Metropolis alone, upon the estimate of the Local Government Board, citizens pay something like £30,000 a year for the purchase of water supplied to them as an adulterant of milk. During the year 1901, out of 7,067 samples examined, no less than 1,072 were found to have been tampered with. Of the samples thus analysed and condemned, 50 were both watered and skimmed, 618 contained added water, and the remaining 384 showed abstraction of fat. As to butter, the adulteration rate has increased in London and the twenty next largest towns, so that it now stands at 12·2 per cent. The importance of enforcing fairly high standards of purity in the case of milk and butter need hardly be insisted upon. In spite of the obvious and elementary nature of that proposition, however, there can be no doubt that the average local authority falls miserably short of its duty in the matter. More than that, it is safe to assert that the whole of the wide field covered by the Adulteration of Food and Drugs Acts is almost equally neglected. The usual plan of taking a sample here and there at random, and of embodying the results in a column at the end of the annual report of the Medical Officer of Health of the district certainly does not ensure an efficient administration of the Acts. It is more than likely that a systematic examination of the shops in a single street would in many cases reveal an infinitely greater number of flagrant food adulterations than those detected in a year from the whole parish by the food inspectors. By the way, it is noteworthy that we hear little or nothing nowadays about the adulteration of beer.

Governmental Cruelty to Animals.

THE humaner spirit of modern times forms one of the favourite topics of newspaper writers and of social reformers. Its influence can be traced in the powerful societies founded for the prevention of cruelty to the lower animals. Its spirit is also embodied in the special laws that have been added to the statute book of the United Kingdom within the memory of the present generation. Indeed, so aggressive has been its mission that it has not hesitated to invade the realms of scientific investigation and to impose restrictions upon experimental research. So long as its demands in the last-mentioned direction are not prohibitive to the reasonable advance of scientific study by means of experimentation they will be readily accepted by the medical profession, which is composed of a body of essentially humane and intelligent men. Recent events in connection with the South African war, however, suggest the question whether the Watch Committee would not do well to extend their criticism to the War Office. *Quis costodiet ipsos custodes?* There can be no doubt that many of the horses sent out to the Cape for the purposes of the campaign were in such a state as to render their employment a matter of refined cruelty. Those wretched animals that have survived the campaign are now apparently being sold by Government. At any rate, a contractor who was summoned to the Guildhall for cruelty to a horse, by working it in an unfit state, declared that the animal had come from the front and he had purchased it from the authorities. The horse was old, decrepit, and had sores on its back. Defendant pointed out the absurdity of the police prosecuting him for working a horse bought under such circumstances, and the magistrate wisely dismissed the case.

Small-pox and Revaccination.

A CIRCULAR has been distributed by the Health Department of the City of London calling the attention of employers and others to the desirability of insisting on the revaccination of *employés* in view of the probability of a recrudescence of the epidemic of small-pox during the coming winter. In order to avoid the rush which takes place under such circumstances it would be well for employers to adopt the example of many large companies in requiring all new hands to furnish evidence of revaccination or to insist on their being revaccinated. In this way the administrative dislocation which results from the revaccination of large numbers of persons engaged by a particular firm can be avoided. We note with pleasure that the City of London sets an excellent example in this, as in many other prophylactic sanitary measures, an example which might advantageously be followed by the municipalities of other large cities in the kingdom.

The Exploitation of the Sick.

WITH commendable pertinacity *Truth* continues to call public attention to the latitude permitted to purveyors of nostrums and useless appliances in their attempts to delude the public, notably to the notorious Drouet Institute and the Viavi remedies. Well may our contemporary express wonder that such persons can with impunity circulate preposterous and utterly untruthful claims under circumstances which in any other walk of life would expose them to a charge of endeavouring to obtain money by false pretences. These are only two of an immense number of products which are bolstered up by unequivocally mendacious statements, but we fear *Truth's* appeal to "the governing bodies of the medical profession" to get the law put on a more rational basis is likely to remain without an echo partly because the governing bodies are notoriously unable to bring any influence to bear on Parliament with this object in view, and partly, no doubt, because the matter is one in which they feel no direct interest.

DR. BROWN, of Preston, had a narrow escape from serious injury one day last week. His horse bolted, and he sustained a severe shaking in his attempt to get out of the carriage, but he fortunately escaped serious injury.

A Revocable Engagement.

A monthly nurse recently brought an action in the Merthyr Tydvil County Court for the recovery of a fee under an engagement to attend a patient during her confinement. She was engaged in May for August, but in June she received notice that her services would not be required. The Judge held that the claim could not be maintained, and gave a verdict accordingly. This decision is in accord with those rendered elsewhere when medical men have sought to recover fees under similar circumstances, but it presses even more hardly on the nurse than on the practitioner. A medical man would not be precluded from accepting any number of other engagements for a given month, whereas a nurse would necessarily have to decline engagements for dates already arranged for. The only way out of the difficulty, apparently, would be for the nurse to insist on a written engagement stipulating the exact conditions under which it might be determined.

PERSONAL.

Sir Victor Horsley is to distribute the prizes at the Faculty of Medicine of University College, Bristol.

Dr. J. Hill Abram has been appointed physician to the Liverpool Royal Infirmary, vice Dr. Caton, resigned.

Sir Thomas Barlow will distribute the prizes to the successful students at the National Dental Hospital on the 29th inst.

Surgeon-Lieutenant-Colonel Hayward Reader has been selected to fill the office of Senior Medical Officer in Lord Kitchener's command.

Dr. Phillips, of Wellington, Herts, has been presented by the inhabitants of the parish with a valuable microscope, and sundry other useful articles, on the occasion of his removing to Halesowen.

Mr. Alban Doran, F.R.C.S., will deliver the Harveian Lectures at the Harveian Society of London, on Thursdays, November 6th, 13th, and 20th, at 8.30 p.m. Subject: "Uterine Fibroids; considered from a Clinical and Surgical Standpoint." These lectures are open to all medical men.

The Lord Lieutenant of Ireland has made the following further appointments to his household:—Physician-in-Ordinary, Dr. Walter Smith, ex-President of the Royal College of Physicians; Surgeon-in-Ordinary, Dr. Edward H. Bennett, ex-President of the Royal College of Surgeons; Surgeon to Household, Mr. J. Lentaigne; Surgeon Oculist-in-Ordinary, Mr. J. B. Story; Surgeon Dentist-in-Ordinary, Mr. H. Gregg Sherlock.

Death from Hydrophobia.

A death from hydrophobia is reported from Glasgow, the victim being a girl, nine years of age, who had been bitten by a young collie dog a few days previously.

The Battle of the Clubs.

It has been resolved by the members and honorary subscribers of the Grantham and Belvoir Rural District Medical Club to submit the dispute between themselves and their medical officers to arbitration at the hands of the Duke of Rutland. It remains to be seen whether this method of terminating the dispute will commend itself to the latter.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

SCOTLAND.

[from our own correspondent.]

REOPENING OF THE UNIVERSITIES AND MEDICAL SCHOOLS.

Edinburgh.—The various medical classes in the University and extra-mural school opened for the session on the 14th inst. without any special ceremony. It has never been customary to inaugurate the academic year by a general address to the undergraduates, and even the custom of individual teachers giving introductory lectures on general topics to their own classes is each year falling more and more into desuetude. Most prefer, and wisely so, to plunge at once into the work of the course. The principal change from previous years, so far as the medical faculty is concerned, is the opening of the John Usher Institute for Public Health. With the opening of the session comes the Rectorial election, Sir Robert Finlay being the Unionist, and Sir Edward Grey the Liberal candidate. The usual election literature is abundant, and the usual raiding of the Liberal rooms by the Conservatives, or *vice versa*, is taking place. Lord Tweedmouth addressed a meeting in support of Sir Edward Grey's candidature on Friday evening.

St. Andrews.—The winter session was formally opened on the 15th by an address from Principal Donaldson, in the United College Hall, additional interest being lent to the proceedings by the installation of Professor Kay to the Hebrew Chair, and Professor Edgar to that of Education. The subject of Principal Donaldson's address was the "Relation of Scottish Universities to State Control." He showed that historically the Scottish theory had been that the State was immediately responsible for the Universities, and was bound to maintain them in full efficiency whatever might be the cost. This was the practice till 1889, when a clause was inserted in the Universities Act to the effect that the sum of £42,300 annually shall be deemed in full discharge of all past and present claims of the Universities. This clause was of purely English origin, and belonged to the range of English ideas. In spite of this final settlement with the Universities, Parliament passed a measure in 1892, granting an annual subsidy of £30,000. The Carnegie Trust, he said, had done great good to the University of St. Andrews, and had come to its aid at a critical time.

Glasgow.—The inaugural address for the opening of the winter session was delivered by Professor Latta, the new holder of the chair of Logic in the University. The subject of the address was "The Old Mysticism and the New Pluralism."

The winter session at Anderson's College Medical School was opened by Dr. Smart, Professor of Political Economy, Glasgow University. He dealt with the profession as opposed to trades, pointing out that in both services were sold for money, but that the characteristic of the tradesman was that he first looked at his wage, while the professional man first looked at the service.

The classes at St. Mungo's College were opened by Professor Hugh Galt, by an address on methods of study.

Glasgow University Rectorial Election.—Considerable excitement prevails at present among the students as to the result of the election for Lord Rector, in succession to Lord Rosebery, who retires. The election takes place next Saturday, the 25th inst., and both parties—those in favour of Mr. Morley, and those for Mr. Wyndham—are equally sanguine of success, as is usually the case. The rooms of the opposing parties are situated in Gibson Street, near the University, and in the evenings a large number of police have been in attendance, as occasionally rather disagreeable, although somewhat harmless, piecemeal battles occur. When the students confine themselves to the piecemeal, the police do not interfere. The exuberant spirits of the students are apt to be shown, however, in a more destructive and dangerous form, such as the smashing of doors and furniture in their rooms. So far nothing very serious has happened.

Glasgow Southern Medical Society.—The annual dinner of this Society was held on Thursday evening, the 16th inst., in the St. Enoch's Station Hotel. Between fifty and sixty gentlemen sat down to dinner, among whom were Professor Stockman, Dr. Haldane, Bridge of Allan; Dr. Cluckie, Greenock; Drs. Forrest, Somerville, Erskine, Connal, Robertson, Carrol, Weir, Carr, Dunning, Stirling, Shaw, Young, and others. The president, Dr. D. McGillvray, occupied the chair. The croupiers were Dr. T. Richmond and Dr. J. Fraser Orr. The chairman, after proposing the usual loyal toasts, gave the toast of "Our Society." He gave an interesting sketch of the Society from its foundation in 1884 down to the present time, with a membership of 200 to 300. Other toasts followed, and the evening was enlivened by music.

An Attack on a Medical Man.—At the Sheriff Court a few days ago a young man was sent to prison for a very unusual attack some time ago on a medical man resident in the northern district of the city when he was robbed of his gold watch and chain. The doctor was incapacitated for work for some time after. He wears several rings on his fingers, and whether this display had anything to do with the attack it is not easy to say. It was the prisoner's first offence.

Aberdeen.—The rectorial election for the University has been fixed for Thursday, October 30th, the Right Hon. Mr. Asquith, M.P., and the Right Hon. Mr. Ritchie, Chancellor of the Exchequer, having been nominated as candidates for the post vacated by Lord Strathcona.

MANCHESTER.

[from our own correspondent.]

The Royal Infirmary Dispute.—During recent years we have frequently had to record the useless discussions of Manchestere's citizens regarding its effete infirmary. Hitherto the board has been stubborn in sticking to its "do nothing" policy, but at last this ancient and autocratic body has been compelled to yield to the pressure of public opinion, and fortunately the majority of its members have resigned. The board's extremity has proved the opportunity for progressive trustees and enlightened citizens. At a special meeting, held on October 16th, the Earl of Derby presiding, the following resolution was adopted:—"That the Trustees confirm the policy that there shall be no rebuilding of the Infirmary on the Piccadilly site; that that building and site be disposed of on terms to be approved by the Trustees and sanctioned by the Charity Commissioners; and that a new Infirmary, on plans to be approved by the Trustees, be built at Stanley Grove without delay, unless a better site can be obtained."

Correspondence.

THE EVIDENCE FOR HETEROGENESIS.

To the Editor of The Medical Press and Circular.

Sir,—What the reviewer of Part II. of my "Studies in Heterogenesis" says, on p. 394 of your last issue (October 8th), of one of the seven subjects of which it treats is calculated to give your readers an entirely erroneous view as to the nature of the evidence presented by me.

His "few control experiments to test the validity of the author's conclusions" in regard to the particular subject referred to are, I submit, as inconclusive as they are irrelevant. I did not question the existence of Monads in hay infusions. I affirmed that Monads of full size can be seen to develop from Zooglœa masses, and your reviewer adduces no evidence to show that any Zooglœa appeared in his inoculated hay infusion—whose constitution had been altered by previous boiling on four successive days. The fact, therefore, that no Monads subsequently showed themselves in this infusion is one which does not surprise me, and it in no way controverts or weakens any statement of mine.

From what your reviewer says no one would dream that the whole section to which he refers is one which has absolutely nothing to do with "pure cultures," but is concerned with the development of innumerable patches of Zooglœa throughout the pellicle that forms on hay infusion, together with the study of the microscopical changes and transformations which they subsequently undergo. I have shown that these "areas" of Zooglœa, varying much in size and shape, exhibit progressive segmentations, with the result that the ultimate units derived therefrom appear either as Fungus germs from which Mycelia develop, or as Amœboid Corpuscles which unfold into actual Amœbæ or into flagellate Monads. Then, again, I have similarly traced, and represented by photomicrographs, the stages by which some Ciliated Infusoria (Kolpodæ) are developed from other Zooglœa masses occurring in the substance of the pellicle. The whole of this section is, in fact, based upon microscopical evidence. It has confessedly nothing to do with "pure cultures," and also rests upon evidence wholly independent of "the ubiquity of Monads and fungus germs."

Who of your readers would ever dream that this was the state of things, having regard to what your reviewer says? When he gets microscopical evidence he ignores it. On the other hand, when such details are less necessary he avers that the problems are "problems of cell morphology and must be studied as such."

One of the subjects to which this last dictum refers is the derivation of Ciliated Infusoria from the segmentation of large encysted Amœbæ of an orange-red colour; and another is the transformation of the entire contents of one of the largest of Rotifer eggs into a great Ciliated Infusorium (Otostoma) by keeping it under certain unnatural conditions for from three to four days. This Ciliate is so rare that it has only once been recorded as having been found in this country, and with one single exception I have only found specimens in, emerging from, or with, the eggs of this particular Rotifer (Hydatina) when they have been placed under certain experimental conditions. Yet I have taken hundreds of this very rare Ciliate from my experimental pots, and always as full-sized organisms about one three-hundredth of an inch in length. I have shown them as such within and emerging from the Rotifer eggs, and I have also represented some of the histological stages by which the eggs have become transformed into the Ciliates—changes wholly unlike any of those even occurring during the normal development of the Hydatina egg.

The proof that this transformation will occur under certain conditions is, as I maintain, absolute; and this is the all-important matter. The question of the precise and detailed histological stages by which the transformation is brought about is quite another and an altogether subordinate matter. Yet my critics demand a "full and definite histological proof of the transformation" before they will entertain the question and examine the abundant evidence already at hand.

Then, again, I have shown in Part I., the stages by which specimens of Amœbæ and Actinophrys have been developed from the endochrome of Confervoid cells; and I have shown the different stages by which other Rotifer eggs undergo simultaneous segmentation throughout their whole mass, the products sometimes developing into Amœbæ, sometimes into Peranemata, and at others into Monads. The criticism in regard to these observations was different. I was told they were unsatisfactory because I had not isolated the resultant forms and studied their future history. But why was this needful? It could only be so on the assumption that in the cases just referred to we had not to do with instances of Heterogenesis, and that the resultant forms might be phases in the life-history of the organisms from which they had been derived. I would ask, however, who supposes that any ordinary Amœba or Actinophrys, for such they were, would develop into a Conferva; or that the Amœbæ, Peranemata or Monads derived from the segmentation of the Rotifer eggs could be stages in the normal life-history of any Rotifer? And if neither of these things was in the least probable why was it necessary for me to have followed their subsequent life history?

Most of these objections are the result of mere superficial and piecemeal criticism; while there is an utter absence of any broad and comprehensive estimate of the value of the evidence adduced, either as testifying to the occurrence of Heterogenesis or of some rival interpretation.

I am, of course, well aware of the weight of preconception opposed to my views, and that I can only expect slowly and with difficulty to gain converts. My diligent search for some years shows me that the evidence of the occurrence of such processes is common and widespread enough, but on account of the preconceptions above referred to it is never looked for by others. Moreover, if the views of my critics as to the way in which the evidence should be sought were adopted, any evidence as to the existence of Heterogenesis would, I believe, stand little chance of being ever forthcoming.

I maintain that isolation, continuous observation, and aseptic conditions are in the majority of cases alike impossible. In seeking for evidence of Heterogenesis we have to study the changes in animal or vegetal organisms when dying, while still in, or not long removed from, their ordinary surroundings; or we have deliberately to place such organisms under certain unnatural conditions, and observe from time to time the changes which have occurred. And then, just as the geologist does in pursuing his studies, we have to put the most reasonable construction—the one which accords best with all the facts—upon the appearances discovered. We have, of course, always to bear in mind, as possible explanations of what we see, the chances of infection by known or hitherto unknown processes, as well as the possibility of the existence of previously unknown phases in the life-history of the parent forms under observation.

These methods are undoubtedly much less conclusive than those of the bacteriologist, or those by which the normal life-history of many animal and vegetal forms has been worked out, but they are the best that are available. The difficulty of isolating the objects which I study is often extreme, if not insuperable; while the placing them under conditions which would admit of anything approaching continuous observation only too often puts a stop to changes previously going on, even if it does not kill the organisms outright; and as to placing them under aseptic conditions this is practically an impossibility. How is it possible to place Confervoid cells, encysted Amœbæ or Ciliates, or Rotifer eggs under aseptic conditions without injuring or actually killing them?

I am hopeful that the facts which I am accumulating will gradually be seen, when looked at broadly and as a whole, and when alternative explanations are weighed fairly and without bias, to be only compatible with the admission of the present widespread occurrence of Heterogenesis—preconceptions to the contrary notwithstanding. And what would be the results consequent upon this change of view? Some of these results I have referred to in an Appendix to Part I, but I would only say here that we should have for one thing a logical explanation (now missing), consistent with the great doctrine of evolution, of the existence of the myriads of lower organisms that are found on the surface of the earth at the present day.

I am, Sir, yours truly,
H. Charlton Bastian.

Manchester Square, W., October 11, 1902.

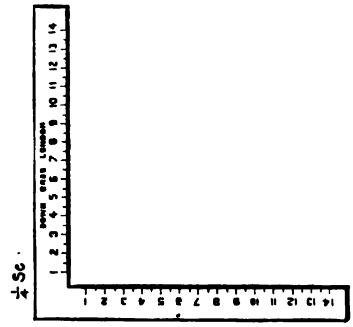
The office of the Principal Medical Officer of the Woolwich Military District, now held by Surgeon-Colonel G. D. N. Leake, is to be abolished, consequent upon the incorporation of the Woolwich and the Thames Districts in the new Army Corps.

New Inventions.

A NEW COXAMETER.

Designed by G. Jameson Johnston, M.A., M.B., F.R.C.S.I.,
Surgeon to the Royal City of Dublin Hospital.

In the course of my clinical teaching I have found difficulties in demonstrating and accurately measuring displacements of the great femoral trochanter. While fully appreciating the merits of Bryant's lines, I am of opinion that, except in gross displacements, they are of little service. This failure is in no way due to the lines themselves, but to the ordinary methods of using them, the numerous sources of error introduced rendering the result very approximate indeed. The difficulties are first drawing a straight line, next drawing two straight lines at right angles over curved surfaces which are somewhat mobile. Discussing the matter with Messrs. Down's representative, he said his firm would endeavour to carry out my ideas. Accordingly, after several experiments with various metals, such as pewter, copper, &c., that firm has succeeded in making for me a coxameter which I have repeatedly found useful in the examination of fractures, dislocations, coxa vara, &c., reaching a degree of accuracy I had not hitherto attained. The instrument, which is simple in the extreme, is in the form of a "square," and made of hammered German silver; it consists of two flexible limbs, permanently fixed at right angles, graduated on both sides of each limb, in centimetres starting from the angle.



The method of use is as follows:—Place the patient in the recumbent position, make a mark with a dermograph immediately over the anterior superior spine of the ilium, and another over the highest point of the great trochanter, placing one limb of the instrument on each so that one is vertical and the other horizontal. The measurements are read off, the horizontal limb indicating upward displacement, and the vertical one the degree of eversion. The instrument is equally applicable to both sides.

Obituary.

WILLIAM CHALMERS, L.F.P.S., GLASGOW.

We regret to announce the death of Mr. Chalmers which took place at his residence, George Street, Glasgow, a few days ago. He had been laid aside from active professional work for a few months. His work was chiefly among the working classes, with whom he was very popular, even the poorest receiving the utmost attention at his hands. Apart from professional work he found time for various public duties, being a member of the Parish Council, as well as chairman of the Ninth Municipal Ward Committee. His loss is much deplored by the people of the east end of the city where he practised.

Death under Chloroform.

A girl, aged nine, died under chloroform at the Cardiff Infirmary last week, and the parents complained that they had not been informed of the necessity for an operation. It appeared that the operation was one of an extremely urgent nature, and according to the medical evidence the chloroform had no share in the causation of death.

Society for the Relief of Widows and Orphans of Medical Men.

At the Quarterly Court of Directors of this Society, held on the 8th inst., the President, Mr. Christopher Heath, in the chair, applications for renewal of grants were read from fifty-four widows, ten orphans, and five recipients from the Copeland Fund, and a sum of £1,321 was voted to be given at the next Court. One widow had become ineligible through marriage for further grants. The deaths of three members were reported. The Directors passed a resolution of regret on the death of Mr. J. T. Ware, F.R.C.S., and V.P., elected in 1845, and at one time acting treasurer of the Society. The election of a member was declared void. It was resolved to distribute at Christmas £590 among the widows and orphans in receipt of grants—£10 to each widow, £3 to each orphan, £5 each to the four receiving special grants from the Copeland Fund.

The Royal College of Surgeons, Ireland. Address to the Lord Lieutenant.

A deputation representing the Royal College of Surgeons, Ireland, waited upon his Excellency the Lord Lieutenant, on Friday last, for the purpose of presenting an address of welcome. The address was as follows:—

"May it please your Excellency—We, the President, Vice-President, and members of the Council of the Royal College of Surgeons, Ireland, desire to offer you our most respectful greetings on the occasion of your arrival in Ireland as the representative of our beloved Sovereign, his Most Gracious Majesty the King. We beg leave, on behalf of our College, to give expression to those feelings of loyalty and devotion to his Majesty's Throne and Person which have ever animated the Fellows and Licentiates of the College since its incorporation by Royal Charter, in 1784. We respectfully desire to draw your Excellency's attention to the work done by our College, which we trust is of considerable service to the community. The functions of our College are primarily to educate young men in all branches of medical science, and secondarily, in conjunction with the Royal College of Physicians in Ireland, to admit them, after due and proper examination, to the various diplomas of the College. That our work is highly productive is shown by the large number of medical men holding our diplomas who are engaged in the practice of their profession, not only in the United Kingdom, but in all the colonies and dependencies of the Empire, and in his Majesty's Naval and Military Services. We claim that not only have we given these gentlemen a sound professional training, but that we have also taught them the higher moral lessons of obedience to the call of duty and unselfish devotion in the execution of it. The proofs of this assertion are to be found in the long roll of Irish surgeons who have in the recent war in South Africa obtained the highest recognition at the hands of our Sovereign and in that happily shorter list of those who have sealed their devotion with their lives. We venture to hope that during your Viceroyalty you may do us the honour of visiting our College, and by inspection of its various departments, satisfy yourself that we are mindful of our duty to his Majesty and his subjects. We pray permission to offer our respectful welcome to the Countess Dudley and family, and to express the hope that your stay in this country may be marked by happiness to yourself and prosperity to those you have come to rule over. We have the honour to be your Excellency's obedient servants,

Lambert Hepenstal Ormsby, President.
Arthur Chance, Vice-President.
Charles A. Cameron, Secretary.
G. F. Blake, Registrar.

The address having been presented, his Excellency thanked the representatives of the College for the address, and for the expressions of loyalty and devotion to his Majesty's throne contained therein, a loyalty which had animated the members of their distinguished college for upwards of a century. He could thoroughly realise the importance of the work carried out by the Royal College of Surgeons in Ireland. To the United Kingdom and the Empire at large, as well as to his Majesty's Naval and Military Services, it has rended signal aid. The name of the gallant young Irish surgeon, Captain Crean, who lately won the Victoria Cross in South Africa, and the noble Dr. Smyth, who died to save the lives of the fever-stricken islanders off Donegal, were fresh in the memory of the British nation, and had added fresh honour to the Irish College from which they came. During his service upon Lord Roberts's staff he had ample opportunities of observing the invaluable work done by the Irish Hospital in South Africa, under Sir William Thompson, a former distinguished President of the College, the history of which they might be justly proud. He was sure that it would always maintain its present high position, and he looked forward with pleasure to a visit one day to inspect the various departments of the College.

A Practitioner Censured.

Dr. Bolton, of Nottingham, attracted an expression of disapprobation from the local Bench last week for having sent a postcard to the police, warning them not to allow a certain patient of his to wander abroad, adding that he would hold the police responsible for anything that might occur, he being of unsound mind. Admitting that a communication of this nature should preferably have been sent in the form of a letter, we see nothing in the act itself deserving of censure. Only by a stretch of the ordinary meaning of the term could it be described as a threat.

Professor Lorenz and the Practice of Medicine in the United States.

Professor Lorenz, of Vienna, whose trip to America in exchange for a colossal fee for the purpose of performing an operation for hip-joint disease has been widely commented upon in the daily press, has, it seems, been called to order for practising medicine there without the required licence. The proceedings were characterised by a suavity which does not always characterise officials over there. He was summoned to appear before the Board of Health, and is reported to have passed an hour answering questions concerning the theory and practice of medicine, whereupon a licence was handed to him, and the sitting came to an end. This retrospective licence will enable the professor to place his services at the disposal of the "crowds" who are stated to be anxious to be operated upon by him ere he returns to Vienna.

Action for Malpraxis.

The trial was concluded at Dundee last week of an action brought against Dr. William Craig, of Cowdenbeath, for the recovery of £500 damages for alleged malpraxis in respect of a child who had sustained several fractures of limbs. It was alleged that the existence of the fractures in question had been negligently overlooked, but ultimately, after a protracted hearing, the jury returned a verdict in favour of the defendant.

Pseudo-Chlorodyne Lozenges.

An inquest was held a few days since at St. Pancras on a child who had died after eating an ounce of "chlorodyne lozenges" bought of a Camden Town chemist. The chemist stated that the lozenges contained no chlorodyne at all, the description being, he admitted, of the nature of "a pious fraud." The chemist, who bought the lozenges wholesale, was unable to substantiate his assertion that there was no chlorodyne in the lozenges, but, as the medical evidence showed death to have been due to quite another cause, the matter was allowed to drop.

More Gratuitous Work.

The police appear to have curious ideas as to the duty of medical men to furnish gratuitous information. Dr. John Stewart, of Soothill, Yorks, having refused information concerning a patient of his unless paid for the certificate, the police managed to obtain the information from the matron of the local hospital, and in court had the audacity to describe Dr. Stewart's conduct as "extraordinary." The extraordinary conduct is that of the police in seeking to obtain the services of the medical man without payment. There is far too much of this sort of thing, and practitioners would do well to impress upon the authorities on every possible occasion that medical assistance in any form is something worth paying for.

Royal College of Physicians of Ireland.

The annual meeting of the College was held on Saturday, October 18th, when the various officers for the ensuing year were elected :—President: D. A. V. Macan. Censors (4): Dr. Bewley, Dr. Wilson, Dr. Coleman, Dr. Peacocke. Vice-President: Dr. H. Bewley. Additional Examiners to take the place of an absent Censor :—Medicine: Dr. Lennon. Medical Jurisprudence and Hygiene: Dr. S. T. Gordon. Midwifery: Dr. Horne. Examiners in Midwifery :—Dr. Glenn, Dr. Jellett. Examiners, in addition to Censors, under the Conjoint Scheme.—Biology: Dr. Cosgrave. Chemistry: Dr. Lapper, Dr. Falkiner. Physics: Dr. Travers Smith, Dr. Winter. Pharmacy, Materia Medica, and Therapeutics: Dr. Drury, Dr. Dempsey. Physiology: Dr. Earl. Pathology: Dr. O'Sullivan. Medicine: Dr. Redmond, Dr. O'Carroll. Hygiene and Forensic Medicine: Dr. Montgomery. College Examiners for the Conjoint Preliminary Examination :—Languages: Mr. William Kennedy, F.T.C.D. Science: Mr. W. E. Thrift, F.T.C.D. Examiners for the Conjoint Diploma in Public Health :—Hygiene: Dr. Bewley. Chemistry: Dr. Lapper. Meteorology: Dr. Falkiner. Representatives on the Committee of Management under the Conjoint Scheme: Dr. Finny, Sir J. W. Moore, Dr. Craig. Representative of the College on the General Medical Council: Dr. Atthill. Treasurer: Dr. Atthill. Registrar: Dr. Craig. Librarian: Mr. R. G. J. Phelps. Agent to Manage the Trust Estate: Mr. Townshend. Law Agents to the College: Messrs. Stephen Gordon and Son. Architect: Mr. A. E. Murray. Walter G. Smith, M.D., F.R.C.P.I., Physician to Sir Patrick Dun's Hospital, was re-elected King's Professor of Materia Medica and Pharmacy, in the School of Physic, of Trinity College, Dublin. The following were elected Fellows of the College :—Stewart Woodhouse M.D., Member of the General Prison Board of Ireland; W. J. Thompson, M.D., Physician to Jervis Street Hospital. The annual banquet was held in the College Hall on the same evening. His Excellency the Lord-Lieutenant honoured the College by his presence.

Royal College of Surgeons, Edinburgh.

At the annual meeting of this College, on the 15th inst,, the following office-bearers were elected for the ensuing year :—President. - Sir John Halliday Croom, M.D. Vice-President.—James Dunsmure, M.D. Secretary and Treasurer.—Francis Cadell, M.B., LL.D. Librarian.—Charles Watson MacGillivray. M.D. President's Council. — Douglas Argyll, Robertson, M.D., LL.D., Joseph Bell, John Chiene, Alexander Gordon Miller, William Craig, M.D., Charles Watson MacGillivray, M.D., Ex-Off. Francis Cadell, Ex-Off James Dunsmure, Ex-Off. Patrick Heron Watson, M.D., LL.D. Representative on General Medical Council.—Patrick Heron Watson, M.D., LL.D. Examiners.—Sir Henry D. Littlejohn, Patrick Heron Watson, John Smith, Douglas Argyll Robertson, Joseph Bell, Robert James Blair Cunyghame, Alexander G. Miller, Peter Hume Maclaren, Francis Cadell, George Hunter, James Dunsmure, Charles E. Underhill, James Ritchie, William Craig, Charles W. MacGillivray, William A. Finlay, Joseph M. Cotterill, James, Hunter, Charles W. Cathcart, Francis M. Caird, Charles H. Thatcher, George A. Berry, James W. B. Hodsdon, Robert McKenzie Johnston, William George Sym, Robert H. Blaikie, Robert A. Lundie, Stewart Stirling, George Mackay, jun., David Wallace, Henry Alexis Thomson, Kenneth M. Douglas, Harold J. Stiles, Alexander Miles, John W. Dowden, Arthur Logan Turner, Henry Harvey Littlejohn, William Guy, Richard J. A. Berry, Theodore Shennan, James Veitch Paterson, Frank Grant Ogilvie, R. Stewart MacDougall, Andrew P. Aitken, James Kerr.

Public Health Examiners.—Sir Henry D. Littlejohn. Robert J. Blair Cunynghame, William Craig, George W. Balfour, M.D., J. Falconer King, F.C.S., George H. Gemmell, F.C.S., Alexander Buchan, LL.D., William Lees, M A.

Dental Examiners.—Patrick Heron Watson, John Smith, Joseph Bell, William Craig, William Guy, L.D.S., Henry Harvey Littlejohn, George W. Watson, L.D.S., Frederick J. Turnbull, L.D.S.

Assessors to Examiners.—Sir William Turner, Douglas Argyll Robertson, Thomas Annandale, Sir Henry D. Littlejohn.

Conservator of Museum (interim).—Theodore Shennan, M.D.

Clerk.—James Robertson, Solicitor.

Auditor of Accounts.—George H. Carphin, C.A.

Officer.—Clarendon Hyde Creswell.

Assistant to Conservator.—George Reid.

The New Hospital for Children.

The new Hospital for Children suffering from Hip Disease, erected at a cost of about £12,000, which is situated on an elevated site on Tubs Hill, at Sevenoaks, was opened on the 16th inst. by Lady Norah Hodgson. In proposing a vote of thanks to her, Sir Henry Burdett remarked that hip disease was an affliction which required a very prolonged period of treatment to effect any lasting result, and the consequence was that an institution of that kind, when properly conducted and the benefits rightly administered, proved a lasting benefit to those children whose parents were so circumstanced that they could not at home find a means to enable the child to have the necessary treatment.

Westminster Hospital Medical School.

Scholarships have been awarded as follows to gentlemen who entered at the Westminster Hospital Medical School on October 1st:—Epsom Scholarship (110 guineas) to Mr. J. A. Hicks. First Scholarship in Arts (£60) to Mr. J. N. Beadles. National Science Scholarship (£60) to Mr. G. G. James. Second Scholarship in Arts (£40) to Mr. A. W. Hayward. Second Science Scholarship (40) to Mr. G. H. Curtis.

Anti-vaccinationist Tactics.

A batch of young "conscientious objectors," who had not been able to satisfy the Chesham magistrates of their conscientious objections, put in an appearance at the Southwark Police Court last week in the hope of meeting with more sympathy. Their expectations were realised, for Mr. Paul Taylor granted the exemptions, remarking that he hoped there would not be an outbreak of smallpox at Chesham.

Pass Lists.

The Royal University of Ireland.

The Examiners have recommended that the following candidates be adjudged to have passed the undermentioned examinations respectively :—

M.B., B.Ch., B.A.O. Degrees Examination.—Upper Pass: * Sydney H. G. Blakely, * William H. N. Bright, * John P. I. Harty, B.A., * Samuel T. Irwin, B.A., * William Warn.

The candidates marked with an asterisk may present themselves for the further examination for honours.

Pass: Robert Best, John D. Buchanan, James H. Campbell, Patrick J. Carroll, B.A., Peter F. Dolan, M.A., Alfred J. Foote, Augustine T. Frost, James W. Killen, Michael M. Lee, B.A., George F. Luke, Francis E. McCune, B.A., James F. G. Martin, Robert Mathewson, Ernest D. Rutherford, William B. Sampson, William J. Sheehan, John Shipsey, Joseph H. Thompson, Edward T. Tuckey.

M.D. Degree Examination.—Pass: Charles E. McDade, B.A., M.B., B.Ch., B.A.O.; Thomas J. MacDonogh. B.A., M.B., B.Ch., B A.O.: Arthur B. McMaster, M.B., B.Ch., B.A.O.; Daniel J. O'Connor, M.A., M.B., B.Ch., B.A.O.; Lucy E. Smith, M.B., B.Ch., B.A.O.

Conjoint Examinations in Ireland.

Candidates have passed the First Professional and Second Professional Examinations as undernoted :—

First Professional.—(*a*) All Subjects: P. J. Cusack, C. Dolan, M. J. Glassey, Jas. O'Brien. (*b*) Completed the Examination: W. R. Burton, A. Hamilton, M. Kennedy, J. J. McGreal, T. O'Brien, F. A. O'Donnell, Jas. Reardon, Miss A. B. Reynolds, E. C. Wallace.

Second Professional.—Old Scheme: W. H. Bournes, Jas. Stuart.

The names of those who have passed Part I. are not published.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Original Articles or Letters intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

THE "CURE" OF CONSUMPTION.

Sir,—In your article under this heading in your issue of Oct. 15th you refer to "my interesting study of the objects and benefits of Sanatoria," published in my last annual report. May I call attention to page 58, line 5-7 of my report? where I expressly state that *the summary was prepared by the Medical Officer of Health for Brighton* (Dr. Newsholme); it was published in his annual report, from which I quoted it. Unfortunately, my signature to my report on page 70 follows closely at the end of this summary, looking as if I claim it, which I had no intention of doing.

Yours faithfully,
D. S. Davies, Medical Officer of Health.

Bristol, Oct. 19, 1902.

Mr. G. Stronach (Edinburgh).—We are unable to devote any further space to the discussion of the Shakespeare-Bacon controversy.

PROBABLE!

The probable reasons for the objections raised against the more general use of the automobile or motor-car, a correspondent suggests, are:—(1) Its detrimental effect on the vaso-motor nerves and (2) motor cortex, and (3) by its continued vibration eventually producing locomotor ataxy!!!

M. R. S.—Evidently in every well-ordered sick-room the management of the nurses must be left in the hands of the medical man in charge of the case. At the same time, as the nurses are paid by the patient it is he who must ultimately decide whether he prefers parting with his doctor to parting with his nurse, in the event of the former proving dissatisfied with the manner in which his directions are obeyed. Difficulty only arises when the medical man is unable to allege positive misconduct, although in reality it is easier to work with an undertrained than with an arrogant or insolent nurse.

D. Q. R.—We should not advise you to seek to enforce the claim. There is no unanimity of opinion among judges on the point you raise, and your reputation might suffer in the event of an adverse decision.

Mr. Ainet.—The blocks were thought to be unsuitable, and were therefore dispensed with. They might, of course, be incorporated in the reprints.

THE ORIGINATOR OF THE RADICAL CURE FOR HYDROCELE.

To the Editor of The Medical Press and Circular.

Sir,—I shall feel obliged by your allowing me to draw attention to the fact that the operation of excising the tunica vaginalis testis as a radical cure for hydrocele was described, performed, and advocated by an English surgeon, Mr. Kinder Wood.

I write this because most medical dictionaries and almost all text-books give the credit to either Bergman or M. Julliond, although Mr. Kinder Wood's description was in print before they were born.

Yours truly,
Oct. 18th, 1902. George Foy.

Meetings of the Societies, &c.

Wednesday, October 22nd.

Dermatological Society of Great Britain and Ireland (20, Hanover Square, W.)—5 p.m. Meeting.

Hunterian Society (London Institution, Finsbury Circus E.C.).—8.30 p.m. Dr. S. Sharkey: The Cardiac Muscle from a Clinical Point of View. (Postponed First Hunterian Lecture.)

Thursday, October 23rd.

Childhood Society (Library of the Sanitary Institute, Margaret Street, W.).—8 p.m. Members' Evening. Papers:—Mrs. S. A. Barnett: On the Principles and Aims of the State Children's Association.—S. de Brath: On Primary Mathematical Teaching.

Chesterfield Lecture, at 6.15 p.m. on "Erythema," by Dr. Morgan Dockrell, at the St. John's Hospital for Diseases of the Skin.

Friday, October 24th.

Clinical Society of London (20, Hanover Square, W.).—8 p.m. Exhibition of Clinical Cases followed by Discussion. Patients will be in attendance from 8 p.m. to 9 p.m.

Appointments.

Brydone, J. M., M.B., B.C.Camb, M.R.C.S., L.R.C.P Lond., Resident Medical Officer to the Bright Ward, Guy's Hospital.

Dawes, J. W., M.B., M.S.Edin., Medical Officer of Health for the Borough of Longton.

Eden, William Annesley, L.R.C.P.Lond., M.R.C.S., L.S.A., Medical Officer of Health by the Wadebridge (Cornwall) District Council.

Frengley, Joseph P., M.D., B.S., R.U.I., District Health Officer under the Department of Public Health of the New Zealand Government.

Hudson, Arthur, L.R.C.P.Lond., M.R.C.S., D.P.H. Cantab., Public Vaccinator for the Kenton District by the St. Thomas (Exeter) Board of Guardians.

Morris A. B., L.R.C.S., L.M.K.Q.C.P.I., Medical Officer of Health for the District of St. Helens, Tasmania.

Okell, George, Jun., L.R.C.P.I., Certifying Factory Surgeon for the Winsford District of the County of Cheshire.

Roll, G. Winfield, M.B., B.C Cantab., F.R.C.S.Eng., Honorary Ophthalmic Surgeon to St. Mary's Hospital for Sick Children.

Scorah, Ernest John, M.R.C.S., L.R.C.P.Lond., Senior House Surgeon to the North Riding Infirmary, Middlesbrough.

Wareham, Sidney J., F.R.C.S.Eng., L.R.C.P.Lond., L.S.A., Honorary Medical Officer to St. Mary's Hospital for Sick Children.

Vacancies.

City of Nottingham Workhouse Infirmary.—Assistant Medical Officer. Resident. Salary £160 per annum, with furnished apartments, board, washing, &c. Applications immediately to Clerk to the Guardians, Shakespeare Street, Nottingham.

County Asylum, Prestwich, Manchester.—Junior Assistant Medical Officer. Salary £150, with board, furnished apartments, and washing. Applications to the Medical Superintendent

County Lunatic Asylum, Lancaster.—Assistant Medical Officer. Salary £150 per annum, with board, &c. Applications to the Medical Superintendent.

Greenwich Union Infirmary.—Junior Medical Officer. Salary £100 per annum, with furnished apartments, rations, washing. Applications to Samuel Saw, Clerk to the Guardians, Guardians' Office, East Greenwich, S.E.

Jenner Institute of Preventive Medicine.—Assistant Bacteriologist for the Serum Department. Aldenham, Herts. Salary £200 per annum, with furnished rooms. Applications to the Secretary, Jenner Institute, Chelsea Gardens, S.W.

Manchester Children's Hospital.—Lady Superintendent. Salary £100 per annum, with board, rooms, washing, and attendance. Applications immediately to the Secretary, Children's Dispensary, Gartside Street, Manchester.

Parish of Fulham.—Assistant Medical Superintendent. Salary £120 per annum, with board, furnished apartments, attendance, and washing. Applications to Edward J. Mott, Clerk to the Guardians, Guardians' Offices, 75, Fulham Palace Road, Hammersmith, W.

Parish of Small Isles.—Resident Medical Officer. Salary £100 per annum, together with private practice. Applications to Jas. Campbell, Inspector of Poor, Small Isles, Island of Eigg, by Oban.

St. Mary's Hospital, Paddington, W.—Bacteriologist. Salary £150 per annum. Applications immediately to the Dean.

St. Mary's Hospital, Paddington, W.—Pathologist. Salary £250 per annum. Applications immediately to the Dean.

Wolverhampton and Staffordshire General Hospital.—House Physician. Salary £100 per annum, with board and lodging. Applications to Edmund Foster, House Governor and Secretary.

Births.

Grayling.—On Oct. 12th, the wife of Arthur Grayling, M.B.Lond. of Forest Hill, S.E., of a daughter.

Harris. On Oct. 15, at Bell Street, Shaftesbury, the wife of W. J. Harris, M.D., of a son.

Sutcliff.—On Oct. 14th, at Park Villa, Torrington, Devon, the wife of E. Harvey Sutcliff, M.B.Dur., of a son.

Marriages.

Crabtree—Purkis.—On Oct. 14th, at St. George's, Hanover Square, Angelo Matteo Crabtree, F.R.C.S.Eng., of Hungerford Lodge, Oatlands Park, to Agnes Constance, elder daughter of the late Charles Blomfield Purkis, of Sturmere, Essex.

Kilkelly—Maquire.—On Oct. 17th, at Bombay, Captain P. P. Kilkelly, Poona Horse, son of Surgeon-General Kilkelly, of Drimcong, co. Galway, and Dublin, to Violet, daughter of Thomas Maquire, Esq., of King's Court, Bray.

Parsons Lappin Reilly.—On Oct. 6th, at St. Columbkille's Church, Kells, by the Right Rev. Monsignor Gaughran, P.P., V.G., William Parsons Lappin, L.R.C.P. and S.Edin., L.F.P. and S.Glasgow, &c., to Margaret, only surviving daughter of Thomas Reilly, Cross Street, Kells. No cards.

Deaths.

O'Brien.—On Oct. 15th, at the Hospital of St. John and Elizabeth London, Ada Hilda, aged 50, wife of Brigade Surgeon Eugene R. O'Brien, M.D. late A.M.S.

Reed.—On Oct. 11, at 34, Culverden Park Road, Tunbridge Wells Dr. Martin Reed, formerly of Hurst Court, Hastings.

INCORPORATED DENTAL HOSPITAL,
IRELAND, Lincoln Place, Dublin.

The Board of Guardians require the services of two gentlemen willing to act as ANÆSTHETISTS. Applications on or before 25th inst. to—

WILLIAM A. SHEA, J.P., Registrar.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

VOL. CXXV. WEDNESDAY, OCTOBER 29, 1902. No. 18.

Clinical Readings and Practices.

I.—PNEUMOPARESIS. (a)

By the late

SIR B. W. RICHARDSON, M.D., F.R.C.P., F.R.S.

BY the term Pneumoparesis I mean a form of disease usually confounded with pneumonia in which the symptoms are due to sudden failure of nervous stimulus to the pulmonary vascular systems, nutritive and respiratory.

Pneumoparesis is unattended by any preceding rigor or by pyrexia, but is preceded by a distinctive train of nervous symptoms consisting of emotional excitement, erythema fugax, and extreme physical prostration, with short cough, accompanied by little expectoration. The mind is impressed with the idea of impending death, but neither alarmed nor anxious, is perfectly resigned. There is no acute pain at any stage. The physical signs are dulness, commencing, as a rule, in the bases of the lungs, posteriorly, but sometimes in patches or centres—with fine crepitation at first, soon becoming moist, and in the later stages with bronchial râles.

The symptoms run a rapid course, usually fatal, and are of a kind such as might be expected if the nervous supply entering by the root of the lung were cut off. Some years ago I produced, in synthetical research, an artificial pneumoparesis in the lower animals—rabbits—by placing them in an atmosphere of amyl nitrite. In these cases the pulmonary paresis was caused by the action of a chemical substance upon the pulmonary nervous structures, and recovery followed upon the withdrawal of the cause; but the effects whilst they lasted were identical, precisely, with those which characterise pneumoparesis in the human subject.

It is as yet a moot point whether the nervous failure commences in the nutritive circulation derived from the thoracic aorta, or in the respiratory circulation of the pulmonary artery. I have devoted a considerable amount of attention to this point. It is a subject rarely studied in relation to pulmonic affections, but it calls for the minutest attention. In regard to pneumoparesis I think, on the whole of the evidence I have seen, that the failure probably is due to paresis commencing in the nutritive pulmonary vessels, and that the obstruction from failure in the respiratory circulation is secondary. Leaving this question *sub judice*, I come next to the study of the nature of the nervous failure upon which the lesion which causes the disease depends.

The primary lesion in the nervous centre may be due to one of three causes:—

(*a*) It may be due to mechanical injury, pressure on, or shock to, the nervous supplying centre or its plexuses.

(*b*) It may be due to the generation within the body of some chemical product which like amyl nitrite reduces to paresis the organic nervous supply.

(*c*) It may be due to hereditary failure or premature exhaustion of the nervous supplying centre under exhausting or depressing influences.

For my own part I am inclined to think that, taking the whole of the evidence into consideration, the balance is in favour of the view that the third supposition is most correct, and we have only to let the mind become accustomed to the thought of the possible arrest of or diminution of nervous stimulus in the pulmonary circulations, as we do in respect to other organs of the body in order to see the fact of pneumoparesis as one of the most simple and clear forms of nervous failure and resultant structural lesion.

But presuming that I am right on this point how wide a field of observation it opens. Most of the aged and infirm die, as by natural anæsthesia, from pneumoparesis under the added influence of cold, privation, fatigue, worry, grief, fear, physical or nervous shock, or some other depressing cause. An aged person goes to bed at night after a day of fatigue or care; he sleeps in a cold room breathing the cold air—the very conditions for the production of pneumoparesis. There is now no necessity of physical shock to the nervous centres; the shock of the cold upon the peripheral nervous expanse of the pulmonary circulation is alone sufficient to produce the paresis, and that mode of death which is so common in the aged, from what is usually called congestion of the lungs.

I think, again, that in those whom we designate as consumptive persons there is the same nervous failure, and that such failure is the predisposing cause of the disease from which they, in the end, succumb. In plain words, pneumoparesis is the natural mode of death in those who have reached the full term of human existence; it is also the mode of death of those who have come to the close of a predestined premature term of human existence.

Returning to the cases of acute pneumoparesis to which my present communication refers. I have now seen five well marked instances of pneumoparesis, and I regret to be obliged to say that they have all ended fatally in spite of every care and every attention to details of treatment. In one instance there was a period in the course of the malady during which there was an apparent intermission of the symptoms, and this so far is hopeful, but even here the improvement was but temporary, whilst in all the remaining cases the course of the affection was, from stage to stage, to death in the steadiest conceivable gradation.

(a) We published some "Clinical Readings and Practices" in 1888, written specially for this Journal by the late Sir B. W. Richardson, the numbers containing which have been long since out of print. So much interest was taken in these papers that quotations from them by past and present writers has determined us to yield to the requests of several of our subscribers to reprint them. The next paper will be on "Hydrops Bronchialis."

In all the acute cases I have yet seen, with one exception, the patients have been women, and they have all borne with them some history of hereditary tendency to chest disease, usually of phthisis pulmonalis. They have also shown in their own persons signs of nervous feebleness with some excitability and emotional disposition. In the one and only example of the affection I have seen in the male subject the patient was advanced in life, but was considered healthy up to the time of his fatal illness. I did not see him whilst he was living, but was requested by his family to make a post-mortem of his body, his death having been very rapid and unexplainable in the ordinary experience. From the symptoms detailed to me, I was able to diagnose the condition of disease and the cause of the death. The symptoms were clearly those of pneumoparesis, induced by exposure to cold. The post-mortem confirmed the diagnosis. Both lungs were congested in the extremest degree, and there was a small exudation of serum into each pleural cavity. There was no other lesion in the body to account for death. The right side of the heart was distended with blood, but the organ was healthy. The abdominal viscera and the brain were healthy.

In another case of pneumoparesis, to which I was summoned, I was very much perplexed. The patient, again a lady, had been ill some days; she presented all the general symptoms of pneumoparesis as I have described them above, but the most careful exploration of the lungs did not enable me to detect crepitation at any part. In this dilemma it was quite impossible for me to declare the presence of pneumoparesis, or to give the precise prognosis which I dreaded. I left the house with the most serious misgivings, hoping in my own mind that I might be wrong after all in my fears. Unfortunately they were only too true. On the third day after my visit I received the information that the patient was dead. The latent disease which I had not been able to discover became pronounced soon after my visit; the lung, on both sides, began to fill up, and death from pure asphyxia took place.

In this last case I did not ascertain whether or not there had been any preceding accident or other exciting cause leading up to the fatal attack. But in all the preceding instances there had been some such cause. In one it was a chill from sitting on damp grass just before the menstrual period. In another a fall, during the seventh month of pregnancy, seemed to have been the source of mischief. In a third some mental trouble seemed to have led to the primary nervous disturbance and failure, and in a further example exposure to cold. In every case the cause was trivial compared with the seriousness of the result.

Treatment of Pneumoparesis.

In the treatment of pneumoparesis, the pathies, one and all, are nowhere, and in this, as in so many other instances, it looks as if the value of treatment receded just as more correct knowledge of cause and causation advanced. The problem is clear, but how is it to be solved? The problem is :—Given a condition in which the organic nervous supply of the pulmonary area, and of the circulation within that area, is suppressed from any cause; how shall the failure be rectified?

In the cases from which I have learned the clinical facts on which the name pneumoparesis is founded every rational mode of treatment was tried; but it was purely tentative. No specific line of treatment was possible. All that could be done was to meet the more urgent symptoms as they arose. Digitalis was administered in one case when the circulation was rapid, but I dare not say that it did any real service. Ergot was used in another case with a like negative result. The ammonia treatment was resorted to once in the hope that by keeping the blood in a fluid state the circulation might be sustained in action and time gained; and, to this nux vomica was also added in free doses, but again without avail. The record, in short, is discouraging from the beginning to the end of the chapter.

In another example of pneumoparesis I shall adopt a practice of a different kind. I shall administer oxygen gas at a temperature of 95° Fahr. so as to endeavour to hold back the asphyxia and to gain time by and for natural restoration of the nervous balance. But even this would not be a radical cure, although in the right direction.

In the debate which took place at the Medical Society of London, when the above paper was read before that learned body, many suggestions were made on the subject of treatment, the plan of employing oxygen by inhalation being, I think, that which met with most favour. My old friend Dr. Routh thought that electricity might be brought into use; but, for my own part, if I were called to another case of the kind I should not know how to apply an electric current in such a manner as to sustain the failure of nervous power. We must always remember that electric excitation, as we know of it up to this time, is a stimulating and exhausting, as distinct from a sustaining, mode of treatment, so that if we could bring it to bear upon the organic nervous function, and, could for a short time, excite or exalt functional activity, we should, in the end, do no more than wear out the remaining natural life and hasten dissolution, That which we really want to do is to recharge the exhausted animal battery, not stimulate it. If a current from a newly charged battery were passed through the wires of a discharged one it might seem to a looker on, who did not see to the bottom of the proceeding, as if the worn out battery were exhibiting new vigour, but it would be seeming at the best, and in unstable textures, like those of organic life, evil, instead of good is most likely to follow upon the experiment of stimulation by an electrical current, direct or intermittent.

MODERN ASPECTS
OF THE
MERCURIAL TREATMENT OF THE GRAVER COMPLICATIONS OF SYPHILIS.

By Dr. LEREDDE,
Of Paris.

The points to be discussed in the present communication are:—(1) The necessity of treating the graver complications of syphilis solely by means of mercurial injections; and (2) the necessity of considerably increasing the doses of mercury at present employed to combat them.

With respect to the preference to be given to mercurial injections, it will be shown later what an important part the dose of mercury introduced into the organism plays in the therapeutics of syphilitic lesions. Now, injections are the only means we possess of administering a definite quantity of mercury. Everyday experience has convinced dermatologists that the therapeutical effect of proto-iodide pills (0 gr. 10 centigr. daily) is inferior to that of a weekly injection of 0 gr. 10 centigr. of calomel, and that the therapeutical effect of inunction, in a daily dose of 6 grammes, is almost invariably inferior to that of the calomel injection. It is not to be supposed that a patient who takes daily 0 gr.

10 centigr. of proto-iodide absorbs the whole of the salt, or that the subject who rubs in say 6 grammes of blue ointment absorbs each day 3 grammes of metallic mercury. The former, indeed, would soon develop symptoms of poisoning, while the latter would become mercurialised after the very first inunction. Moreover, it is highly improbable that the intestine in all patients, absorbs the same quantity of proto-iodide even when administered in similar quantities, still less that the inunctions are followed by the absorption of a similar quantity of mercury in all subjects, through the skin or the lung (since a portion of the mercury is absorbed by the latter). We may take it therefore that there exists one, and only one, method at the present time, by means of which we can introduce a known quantity of mercury into the organism, viz., by injection, and whenever we wish to obtain the maximum curative effects of mercury without the toxic effects no other procedure is open to us than the method of injection.

My next point is that the therapeutical effect of mercurial injections depends on the dose of mercury introduced into the organism. I do not attach the slightest importance to the particular salt employed, soluble or insoluble, with regard to its therapeutic efficacy, which is the only point which we need consider. The therapeutical efficacy of a mercurial compound depends, I believe, solely on the quantity of mercury introduced into the organism in a given time. Statements bearing on the superiority of this or that salt (with regard to its efficacy) are contradictory, and may be explained on the ground of individual predilections.

It may be well to enumerate the various mercurial compounds in general use, giving the quantity of mercury contained in each, in order that we may institute a comparison between them :—

Mercurous chloride (calomel)	$Hg_2\ Cl_2$	— 84·92%
Mercuric chloride (sublimate)	$Hg\ Cl_2$	— 73 80%
Mercurous iodide	$Hg_2\ I_2$	— 61·16%
Mercuric iodide (biniodide)	$Hg\ I_2$	— 44·05%
Benzoate of mercury ...	$(C^6H^5CO^3)^2Hg$	— 45·25%
Cyanide of mercury... ...	$(C\ Az)^2Hg$	— 79 32%

This table shows that, of the soluble salts, the cyanide and sublimate (79 and 73 per cent. of Hg) contain nearly twice as much mercury as the benzoate and biniodide. Their therapeutic activity, in my experience, is obviously superior, in similar doses, and their toxic effects are more marked. Calomel is, of all the salts in general use, the richest in mercury, since we have almost given up the use of the yellow oxide; but we must ask ourselves how it comes to pass that calomel, according to most dermatologists, should be therapeutically superior to the soluble salts, and even to grey oil, in the treatment of the obstinate syphilides of the skin, which enables larger doses of mercury to be injected? To inject 0 gr. 10 centigr. of calomel every week is to introduce 0 gr. 08 centigr. of mercury into the organism. Now, by the injection, as is sometimes practised, of 0 gr. 015 milligr. of corrosive sublimate daily we obtain in a week a similar dose of mercury. To what are we to attribute the superiority of calomel, if the nature of the salt possesses no importance? It is easy to answer this question if we reflect upon the manner in which calomel acts on the organism. Every injection of this salt is followed not only by a loud reaction, but also by a general reaction. The rise of temperature and lumbago pain, which last for at least three days, can only be attributed to intoxication. We must admit that, during these three days, three-quarters, and perhaps more, of the calomel introduced into the muscle is absorbed. This, I think, is the only plausible explanation of the at times heroic action of an injection of calomel; it enables us to introduce into the circulation, in a very short space of time, a quantity of mercury infinitely greater than that which is introduced by any of the methods we usually employ, amounting possibly to 0 gr. 02 centigr. of mercury daily during the days following the injection. As to the injections of grey oil, they provoke neither marked local nor a general reaction; it is evident that this preparation is but slowly absorbed, as is proved by the tardy supervention of stomatitis one, two, or three weeks thereafter.

I really think that this question of dosage occupies a foremost place in any consideration of the mercurial treatment; if the cure of syphilitic patients depends on the mercury, it also depends on the action of a known quantity of mercury, a fact which I do not think has hitherto been pointed out. Moreover, all cases of syphilis are not cured by the same doses. In view of the slight difference between the quantity sufficient to effect the cure of a particular case and the insufficient dose, I think that the following law may be promulgated:—"Syphilitic lesions (I refer to active lesions) refractory to a quantity of mercury A, yield to a quantity A + a;" that is to say, when curative effects do not follow a known dose of mercury, it is only necessary to increase this dose to effect a cure. I may add that we must not rely on accumulation, or on the effect of the mercury, at the end of a certain period of absorption; the great point is the quantity of mercury taken into the organism in twenty-four hours.

These statements are the direct outcome of observations on cutaneous lesions treated with mercury, and the following very important conclusion may be deduced therefrom, viz., that we often meet with syphilitic lesions of the viscera, and particularly of the nervous system, which are believed to be refractory to anti-syphilitic treatment, but which, like certain cutaneous lesions, might be cured by the employment of larger doses than those usually resorted to. Before we pronounce them to be incurable therefore, it is our duty to push the treatment.

Now let us see in what way we may improve the mercurial treatment. In an interesting case reported by Dr. A. Robin, that of a young woman suffering from grave syphilitic iritis, threatening the organ of vision, the condition had withstood an injection of 0 gr. 10 centigr. of calomel, but was cured by the daily injections of 0 gr. 05 centigr. of benzoate of mercury for eight days, then of 0 gr. 03 centigr. for three weeks. What struck me particularly in this case was the fact that the benzoate of mercury proved therapeutically more active than calomel, but this was because Dr. Robin had employed it in much larger doses than usual. At that time I held the general view of the superiority of calomel over the other salts of mercury, a sort of specific superiority due to its being calomel; and I believed, like everyone else, that the injection of insoluble compounds gave better results than those of soluble preparations. At present this hypothesis appears improbable, for why should mercury be less active in the soluble than in the insoluble state? This statement is only correct when, as at the present time, we employ in injections of soluble salts only small doses, whereas in injections of insoluble salts we use stronger doses, so that the latter are necessarily the more active.

If we inject larger quantities of soluble salts of mercury we shall see that soluble preparations are more active than insoluble salts. At this point it may be asked whether the employment of larger doses of mercury does not expose the patient to grave dangers. A fact based on the study of the mercurial treatment, in all its phases, is that between the therapeutical dose and the toxic dose there is but a slight difference, and when we attempt to increase the former we incur the risk of mercurialism, with its disastrous buccal and cutaneous manifestations and constitutional disturbances.

Looking at the matter calmly, none of these dangers appear to be very great. It is a mistake to suppose that the toxic doses approximate so closely the therapeutical doses. This mistake arose at a time when the administration of mercury was not carefully regulated, when 0 gr. 10 centigr. of proto-iodide was given without any attention being paid to the amount absorbed, when six grammes of blue ointment was rubbed in in order to procure the absorption of a few centigrammes of metallic mercury. It is not surprising that from time to time grave troubles arose. I have referred to the fact that Dr. Robin was able to inject a daily dose of 0 gr. 05 centigr. of benzoate of mercury (0 gr. 022 milligr. of Hg) for eight days without any untoward symptoms. M. Lemoine stated, at the Toulouse Congress of Medicine, that he had cured patients suffering from ataxy and general paralysis by daily injections of from 0 gr. 06 centigr. to 0 gr. 08 centigr. (0 gr. 036 milligr. of Hg) of benzoate of mercury; M. Lepine also stated that he had injected 0 gr. 06 centigr. of biniodide daily in certain syphilitic subjects (0 gr. 026 milligr.), and in no case is any mention made of toxic sequelæ.

The doses of calomel generally injected (0 gr. 10 centigr. per week, *i.e.*, 0 gr. 084 milligr. of Hg) are much lower than those I have mentioned, and I may recall the fact that the earlier authors recommended the use of injections of calomel containing up to 0 gr. 15 centigr. and 0 gr. 20 centigr. of this salt each week (0 gr. 12 centigr. and 0 gr. 16 centigr. of Hg). These quantities of benzoate, biniodide, and calomel are much larger than the doses which we daily employ in injections. I do not refer either to inunctions or ingestion, since when prescribing inunctions or pills we never know what proportion of the mercury the patient really absorbs.

Syphilographs then use mercury in small doses. The great majority of cutaneous lesions, as a matter of fact, yield to 0 gr. 10 centigr., and even 0 gr. 05 centigr. of proto-iodide daily, teaspoonful doses of the solution of the perchloride, to inunctions of 4 gr. daily, a daily injection of 0 gr. 01 centigr. (0 gr. 008 milligr. of Hg) of cyanide or even of 0 gr. 01 centigr. (0 gr. 0045 decimilligr. of Hg) of benzoate, or even to 0 gr 004 milligr. of biniodide, following the formula of M. Panas (0 gr. 0017 decimilligr. of Hg). We have acquired the habit of prescribing mercury in these doses. If we have to treat grave or obstinate visceral lesions we prescribe without hesitation, "by tradition," frictions of 4 or 6 grammes of blue ointment daily, or injections of soluble salts in the doses mentioned above, which, although they cure ordinary cutaneous lesions, do not suffice to cure all cases. Neurologists, in the treatment of grave, obstinate lesions, are guided by the facts adopted by dermatologists for the treatment of cutaneous lesions which readily yield to treatment.

We ought, however, to bear in mind that, in treating visceral lesions, we should devise some other method than that used in the treatment of cutaneous lesions, since the latter are not of any immediate importance, while the former are often of the gravest nature. Therefore we ought always to aim at effecting a cure in the shortest possible space of time. If we have to do with spinal or cerebral lesions it may be a question of hours, because at any moment the obliteration of a vessel may be irremediable, and lead to softening. The question of dose is also of extreme importance, since there exists in the brain and spinal cord lesions which, like certain cutaneous manifestations, resist inadequate doses.

Mercurial stomatitis depends essentially on the state of the buccal mucous membrane. One patient may be able to tolerate without stomatitis a large dose of proto-iodide, while another cannot tolerate a much smaller dose. The same observation applies to inunctions and injections, either of soluble or insoluble salts. Persons who have the teeth and gums in good condition, cleaned by a dentist if there be the slightest doubt as to the state of the teeth at the commencement of the treatment, and who take the indispensable and minute care in regard to cleanliness, are able to tolerate a very large dose of mercury without stomatitis.

Mercurial stomatitis may be avoided even when large doses are employed, though, of course, the chances of its being produced are greater when the doses are stronger, but, directly it is apprehended, the necessary precautions must be taken, in order that it may not interrupt the treatment.

The only fact to be taken into consideration in the determination of the maximum doses of mercury is furnished by the symptoms of mercurial intoxication, fever, backache, prostration, &c.—phenomena which follow fairly often an injection of even 0 gr. 10 centigr. of calomel—giving rise to troubles possibly more serious than the specific manifestations which we are trying to cure.

From what precedes, we may draw certain practical conclusions in the direction of modifying the treatment of grave syphilitic troubles by increasing the doses, and by increasing the quantities of soluble salts or calomel introduced into the organism. We may, like MM. Robin and Lemoine, employ benzoate of mercury in daily doses of from 0 gr. 05 centigr. to 0 gr. 08 centigr., or, like M. Lépine, the biniodide in doses of 0 gr. 06 centigr. If we prefer to employ the sublimate or cyanide, we must bear in mind that these salts contain more mercury, and should be administered in doses rather less by one-half than those of the biniodide and benzoate. I have recently prescribed the cyanide in daily doses of 0 gr. 03 centigr.

Generally, when we desire to give mercury in doses as strong as those I have just mentioned, it will be preferable to inject the soluble salts, because it will be easier to stop the absorption of the mercury should stomatitis or general phenomena of a toxic origin supervene, or should the kidneys be affected to such a degree as to compel the treatment to be suspended. Nevertheless, I should not be surprised if it were found to be of great advantage to employ calomel in the dose in which it was formerly prescribed, of 0 gr. 15 centigr. or 0 gr. 20 centigr. per week. But instead of making a weekly injection, two injections, one of 0 gr. 07 centigr. or 0 gr. 10 centigr. each week might be made. In this manner the sudden and forcible action of calomel will be rendered available, and there are certain cases, of tabes for example, in which special advantage attends the injection of insoluble compounds, injections of soluble preparations being a very painful method of treatment for the patient.

Let us now examine the conditions under which large doses of mercury are indicated. It is evident that in all cases in which the syphilitic troubles yield to the usual doses we must continue to employ them. But we must prescribe larger doses (*a*) when mercury is administered as a means of diagnosis; (*b*) when experience shows that the ordinary doses are not curative; (*c*) in every case in which, not knowing the necessary dose, we have to treat a patient suffering from troubles which require to be cured rapidly and completely; in other words, when a normal dose might be insufficient to prevent irremediable mischief. Let us take, for instance, the case of a patient suffering from cutaneous complications, such as palmar or plantar lesions, tuberculo-gummatous lesions, spreading eccentrically, or even lingual troubles of syphilitic origin. These cases are incurable by the ordinary mercurial treatment; they are, therefore, cases in which the doses must be increased. Generally the injection of 0 gr. 10 centigr. is sufficient; while, if we prefer to inject soluble salts, we employ the sublimate or cyanide (0 gr. ·02 centigr. at least), or the benzoate (in doses of 0 gr. 0·4 centigr.), instead of keeping, as is usual, to injections of 0 gr. 01 centigr. of cyanide or benzoate daily. If the lesions resist we may still further increase the dose. We can act in the same manner with more deeply-seated lesions, such as osseous or articular lesions. When, however, the question of time is of secondary importance, we must only give the strong doses after trying the effect of the usual doses.

In lesions of the nervous system we ought always to employ maximum doses, especially in the manifestations which everyone recognises to be syphilitic, since it is necessary to give sufficient doses in order to prevent the appearance of grave troubles, and we must not wait till these troubles appear and then perceive that we have not acted with sufficient promptitude.

The maximum doses ought also to be employed in tabes, general paralysis, and other affections of the nervous system, which M. Fournier described as parasyphilitic. In my opinion tabes and general paralysis, along with other "parasyphilitic" affections, are distinctly syphilitic diseases, amenable to mercury, on condition that the treatment is started soon enough, and with sufficiently high doses.

Among the unsuccessful results of the mercurial treatment, some are due to (*a*) the fact that perhaps cases of general paralysis and tabes are not invariably of syphilitic nature and origin; (*b*) the fact that in tabes and general paralysis we often, I should say nearly always, begin the treatment too late; also, because owing to a frame of mind which I cannot quite understand, which induces neurologists and even syphilographs to do their best to bring forward evidence of unsuccessful results and drawbacks of the treatment, we are led to believe that a tabetic or paralytic subject cannot be cured by this treatment, although successful cases of this treatment have been freely adduced.

I believe the unsuccessful results of the mercurial treatment in cases of tabes and general paralysis are especially due to inadequate treatment. Dr. G. Ballet made a statement at the Congress of Toulouse, which merits special attention. "We have," he says, "no success in tabes and general paralysis treated by the mercurial methods. I mean those treated by syphilographs. I assert, that to practise daily frictions with 4 grammes of blue ointment, in patients suffering from nervous syphilitic troubles, is to employ an inadequate treatment, and this treatment is peculiarly inadequate when we have to do with diffuse syphilitic lesions, such as those of tabes and general paralysis. In these affections, the mercury ought only to be prescribed in injections, and, as a general rule, we ought to employ doses of 0 gr. 03 centigr. or 0 gr. 04 centigr. of strong salts (cyanide or sublimate), of from 0 gr. 06 centigr. to 0 gr., 08 centigr. of feeble salts (benzoate or biniodide). In the future we may possibly use still more energetic means. We might also try to make two injections per week of calomel, in doses of 0 gr. 07 centigr. or 0 gr. 10 centigr. each."

I have not exhausted the list of modifications which the mercurial treatment might advantageously undergo. It may be that the remarkable action of calomel in tolerably small doses may lead to our making a single injection of a soluble salt in a very large dose, waiting for the mercury to be eliminated before the dose is repeated. The question of intravenous injections must remain open, the doses employed by Dr. Abadie not permitting us to estimate the superiority of the method.

I may conclude by stating that mercury may be employed more energetically than has been usually done, without any actual danger to the patient, for the cure of grave syphilitic troubles, and that we shall in this manner doubtless obtain results which were formerly denied to us.

LYSOFORM: A NEW ANTISEPTIC.

By F. W. TUNNICLIFFE, M.D., and
R. T. HEWLETT, M.D.,

Of the Pharmacological and Bacteriological Laboratories,
King's College, London.

The chief desideratum of an antiseptic is that it shall possess adequate germicidal powers, and yet at the same time not be an active poison to the higher animals. The importance of this latter property comes into consideration with regard to the use of an antiseptic in two distinct ways. In the first instance, it may be often desirable to obtain the germicidal action of an antiseptic in the living body. As an example of this, the internal use of antiseptics in pulmonary diseases and certain intestinal conditions may be cited. It is obvious that, however great the germicidal power of a given antiseptic may be, if it is an active poison its employment for the above purposes is much limited. Further, an antiseptic is often required for local application in the living body, as, for instance, in the disinfection of suppurating cavities, &c. In the choice of such a substance not only its germicidal power but also its relatively non-poisonous nature must be taken into consideration. Again, supposing an antiseptic be simply required for household disinfection or for rendering innocuous some pathological product, entirely outside the body, such, for instance, as tuberculous sputum or typhoid stools, it is of great advantage to make use of some agent which is not an active poison. More especially is this the case if the antiseptic in question possesses not only germicidal but also deodorant properties. *Pari passu* with the education of the public concerning the *vera causa* of zymotic disease is the domestic use of antiseptics increasing; one result of this is that the use of antiseptics is falling more and more into the hands of a public untrained in scientific method, and often entirely unaware of the, in many cases, highly poisonous nature of the antiseptic they are employing. Consequently, domestic antiseptics are often left about in homes carelessly, and are not seldom the causes of accidental poisoning. The frequency of such cases led to an order of the Privy Council some two years ago to the effect that all preparations containing more than 3 per cent. of carbolic acid or its homologues should be regarded as poisons. It is obvious that the use of a non-poisonous antiseptic, if such could be found, would do much to prevent the occurrence of such cases. Speaking generally, however, although the protoplasm composing the bodies of different bacteria differs sufficiently not only from that of higher animals, but also from that of other morphologically similar germs, as to render the power of any given antiseptic different in the case of different bacteria, yet nevertheless the most active antiseptics known are active general protoplasmic poisons, and conversely those antiseptics which are not active poisons are, speaking generally, possessed of less pronounced antiseptic power. The difference essentially, however, between a very powerful antiseptic and a less powerful one is that to obtain a given germicidal result one has to use more of the latter than of the former. This resolves itself ultimately into a question of expense. What one has therefore practically to decide is whether it is not worth while to pay relatively more for a substance which is non-poisonous in the quantity required for use, and with which accidents of all kinds must be exceedingly rare.

In the choice of an antiseptic regard must also be had to its effect upon the special senses. One of the most powerful antiseptics known is formic aldehyde, or as it comes into commerce in the form of a 40 per cent. solution, formalin. This liquid is, however, so irritating to the nose and eyes and all mucous membranes with which it may come into contact, that its sphere of usefulness is greatly curtailed. The same may be said of many of the carbolic acid preparations which possess a very penetrating and disagreeable odour. The special uses to which we may wish to put an antiseptic may also lead us to give preference to certain antiseptics having definite physical properties. For instance, no one objecting to the smell of iodoform would use this substance as a deodorant. Again, a very common use of antiseptics is to disinfect the skin, and for this purpose those antiseptics which form a lather when rubbed on the skin have a great advantage over others, for by them, in that they can more easily gain access to the epidermis, the skin can be much more perfectly disinfected.

It will be seen from what follows to what extent the new antiseptic, lysoform, fulfils the above conditions, and hence for what purposes it will be especially useful.

Lysoform owes its antiseptic power to its formic aldehyde moiety. The enormous germicidal power of formalin may to some extent be appreciated if we call to mind the fact that one part in ten thousand of this substance exerts a powerful germicidal action, and that even one part in forty thousand will prevent for a considerable time the souring of milk. Lysoform may be regarded as a formic aldehyde soap, and is a colourless somewhat viscid liquid, superficially very similar to glycerine. It is miscible with water in all proportions, such solutions have, however, a tendency to become somewhat turbid on standing. The formic aldehyde contained in it is almost somewhat volatile, hence neither lysoform nor its solutions should be heated above 100° F. It is important, therefore, that solutions of lysoform intended for use should be freshly prepared. It has an agreeable odour, and the formalin it contains is almost completely masked, being just discernible on deep inspiration by a slight tickling, which it produces at the back of the nose or mouth. Undiluted, and rubbed well on the hands, a soap is formed with decided cleansing properties, but when used in this concentration formaldehyde vapour is evolved, and can readily be perceived. If diluted with an equal quantity of water, *i.e.*, if used in a 50 per cent. solution, the same soap is formed with cleansing properties, and the evolution of formic aldehyde is not sufficient to be in any way objectionable. If used in still greater dilution a soapy lather is also formed, and the aromatic smell of the compound is alone perceptible. Even when used undiluted lysoform produces no numbness, tingling or subsequent roughness or peeling of the skin. This property of soap formation, together with its unirritating qualities, should render lysoform valuable for skin disinfection.

Deodorising Properties.—Lysoform has a powerful and rapid action as a deodoriser. One c.c. of a 10 per cent. solution immediately and completely destroyed the odour of 20 c.c. of putrid broth, and 2 c.c. of the same solution acted similarly upon 20 c.c. of foul and putrid milk. In other words, it acted in both these cases as an efficient deodoriser in the proportion of 1 in 200 and 1 in 100 respectively.

Action upon Mucous Membranes.—One of the uses of an antiseptic is obviously as a gargle or irrigating fluid for mucous cavities. Lysoform can be used for this purpose without causing any irritation in strengths varying from 1 to 4 per cent. This corresponds approximately to a strength of from one to six teaspoonsful to the pint. Stronger solutions may be used with the less sensitive mucous membranes.

Germicidal Action.—In order to test the germicidal action of lysoform the following method was employed: A fresh surface-agar culture of the micro-organism to be tested was prepared. A little of the growth was emulsified in some sterile distilled water so as to produce a slightly opalescent emulsion. Measured quantities of this emulsion were then mixed with measured quantities of a solution of lysoform in sterilised distilled water (5, 10, or 20 per cent.), so as to form a definite percentage of lysoform in the mixture. Thus, for a 5 per cent. mixture equal volumes of emulsion and of 10 per cent. lysoform solution were mixed together. The mixture was well shaken and then allowed to stand and at timed intervals three platinum loopfuls of it were sown into tubes of sterile nutrient broth, and these inoculated tubes subsequently incubated. If the organism had been killed by the antiseptic no growth ensued in the inoculated tube, and the broth remained clear; but if the organism had not been killed, growth took place and the broth became distinctly turbid. Sterile test tubes, pipettes, distilled water, &c., were used throughout and the results controlled.

The organisms that were used for these experiments were the typhoid bacillus, the bacillus coli, and the staphylococcus pyogenes aureus. It would be superfluous to give the full experimental protocols of this research; the conclusions arrived at, however, are as follows. The typhoid bacillus is killed by a 5 per cent. solution of lysoform in between five and ten minutes. The bacillus coli is killed by the same strength solution in between ten and twenty minutes. The staphylococcus pyogenes aureus is killed by a 5 per cent. solution of lysoform in a little over an hour. From these results, the general conclusion can be drawn that lysoform acts as an efficient germicide when used in the strength of a 5 per cent. solution, or approximately six teaspoonsful to the pint. In this strength it has no irritating properties either upon the skin or mucous membranes, and makes, when rubbed on the skin, a good lather.

Pharmacology of Lysoform.—As has been said above, the active constituent of lysoform is formic aldehyde. It is a well-known fact that, although this substance is one of the most active antiseptics known, and combines energetically with many organic substances, especially proteids, yet, nevertheless, to the higher animals it is relatively non-poisonous. A spoonful of formalin, taken apparently raw, was not fatal. The only case of poisoning from formic aldehyde reported up to 1901 (the original account of which we have never been able to find) was after 2·5 grammes of this substance taken at one dose. Recently formic aldehyde has been introduced directly into the blood of patients continuously for some time without any poisonous symptoms accruing. The compounds and modifications of formic aldehyde seem to be practically innocuous; for instance, Trillat gave the polymerised solid modification of formic aldehyde in drachm doses to patients without any poisonous symptoms. Aronson records similar experiences with paraformaldehyde. An ammonium compound of formic aldehyde, viz., urotropin, is given largely in medicine as an urinary antiseptic in considerable (ten grains) doses. As far as we have been able to ascertain, the formic aldehyde compound contained in lysoform has a very low toxicity either when given by the mouth, or injected either under the skin or into the peritoneal cavity. In the case of kittens the lethal dose was from 1·5 to 2 c.c. pro kilo body weight when injected into the peritoneum. We never succeeded in poisoning a kitten by this substance per os; when large doses were given the animal vomited and appeared in this way to avoid poisoning. Under these circumstances it would be very difficult for poisoning to occur with this substance, and it may correctly be described as belonging to the class of non-poisonous antiseptics, though, of course, the term non-poisonous is always a relative one. Further, should by any possibility a large quantity of lysoform be swallowed and vomiting not occur, the treatment indicated would be to give the patient ammonium acetate and subsequently an emetic.

Clinical Uses of Lysoform.—From the above facts it is obvious that lysoform will be likely to recommend itself as an antiseptic for clinical purposes, and to those who intend to make a trial of this substance the following directions for use will perhaps be of help. As an antiseptic mouth or nose wash it should be used in the proportion of from one to three teaspoonsful to a pint; as a vaginal or uterine douche in the strength of from four to six teaspoonsful to a pint; for abscess cavities, suppurating sinuses, &c., up to six teaspoonsful to the pint or stronger; for disinfecting the hands or instruments, the strength should be from six to twelve teaspoonsful to the pint. For skin disinfection, the parts should be well rubbed with the solution, which will form a lather. As a deodorant, lysoform will be found efficacious in the proportion of from half to one fluid ounce to the gallon. To disinfect fæces, or other pathogenic discharges, a solution of lysoform containing half an ounce to the pint should be used. These directions are in strict accord with the ascertained bacteriological facts, but clinical experience with lysoform has shown that it exerts a marked inhibitory action upon bacterial growth in solutions of weaker strength than those recommended above; it would be well, therefore, in using this substance clinically, to begin in each case with the weakest solution mentioned above.

Conclusions.—The property which lysoform possesses of forming a lather, together with the fact that it is non-irritating and non-anæsthetic, should render it especially adapted for skin disinfection. In comparing lysoform with other antiseptics at present in use, we regard its low toxic equivalent as a distinct advantage, and likely to render its sphere of usefulness a wide one.

[For references see Tunnicliffe and Rosenheim, *Journal of Hygiene*, Vol. I., No. 3, page 332.]

ABSTRACT OF INTRODUCTORY ADDRESS
DELIVERED AT THE
OPENING OF THE WINTER SESSION AT THE ROYAL VICTORIA HOSPITAL, BELFAST.

By W. B. McQUITTY, M.A., M.D.,
Assistant Physician.

After cordially welcoming the students in the name of the staff the lecturer proceeded to discuss the inferior position accorded to medicine in comparison with the professions of Divinity and Law, and gave as reasons the association in former times of superstitious credulity with the practice of medicine, and the idea that any profession which necessitates the performance of manual work must *ipso facto* be regarded as inferior to the purely literary occupations. The attitude of the medical profession towards the study of preventive medicine was next taken up, and the fact dwelt upon that sufficient credit had not been given to its members for their disinterested action in successfully endeavouring to stem the current of disease with the necessary consequence of reducing the amount of work available for them.

The necessity for precision of observation was urged upon the student, and illustrations of defective and acute observation adduced. The inestimable importance of case-taking was especially emphasised and attention drawn to the fact that progress in medicine dated from the time of Sydenham, when clinical histories were first regularly taken.

Since the close of the summer session, remarked the lecturer, a noteworthy and an epoch-marking event had taken place in the medical history of Belfast. His Majesty the King had conferred the dignity of knighthood upon the senior physician whom they were all gratified to be able to address as Sir William Whitla, and to whom they now tendered their hearty congratulations. So far as the medical profession is concerned, this honour was without precedent in Belfast, where hitherto such distinctions have been almost exclusively reserved as rewards for political or municipal services. Whether they regarded Sir William Whitla's reputation as a writer, his eminence and skill as a physician, or his munificence to his profession in the gift of the Medical Institute now rapidly approaching completion, it was a matter of universal agreement that the honour had been well earned and worthily bestowed. Granted as it had been on personal grounds, and not because the recipient happened by the accident of chance to fill some public office, it is all the greater honour to the profession in Belfast, and, indeed, in the province of Ulster. Up to the present in Ireland, professional knighthoods, if he might use the expression, had been awarded only to practitioners in Dublin, but he hoped it was not too much to expect, now that a precedent had been established, the northern province might receive its due proportion. He ventured to entertain the hope that at the beginning of next session Sir William Whitla might have a colleague to share his position of "splendid isolation," and that he (the lecturer) on that occasion might have the pleasure and privilege of extending his congratulations and theirs to another member of the staff of that hospital.

The present session would probably be the last opened in that building; shortly the new Hospital would be in occupation, and with the increased accommodation the facilities for teaching would be greater and the students' opportunities for practical work more numerous. The new hospital would be one factor in lightening the burden on the student, and would afford advantages which ought to enable the Belfast Medical School to keep pace with its older rivals. With regard to Queen's College, we believe he but echoed the wish of everyone present that whatever be the result of the Royal Commission now sitting, or whatever their views on the University question, they were united in hoping that one outcome of the attention focussed on higher education might be the proper equipment and adequate endowment of their college.

Clinical Records.

A CASE OF NEURASTHENIA TREATED BY SURGICAL MEANS.

By J. Stuart Nairne, F.R.C.S.,
Senior Surgeon, Glasgow Samaritan Hospital for Women.

A. B., æt. 18, was admitted to St. Margaret's Home on February 7th with distension of abdomen, hæmorrhage, &c. This is probably the earliest case in which a diagnosis of neurasthenia was deliberately concluded and a trial made of surgical means in a minor degree to meet the condition by me.

She was a very young girl, of an amiable disposition, and I look back on her case with the most vivid recollection. Her old father and mother came with her, decent country people who had never had any personal experience of neurasthenias or hysterias or anything of that sort. They said she was always ailing, pains here and there and everywhere: could do nothing: was always willing to do anything, but failed; pains in her back, pains in her side, great distension of her abdomen, rollings and rumblings of flatulence, a restless sleeper, a bad eater, with constipation sometimes of nearly a week's duration. She had been under treatment for a considerable time with tonics and purgatives, till finally it was considered a case of nerves, and both she and her parent were disheartened. Nothing seemed to do her any good. If she felt well for a little while she was bright, cheerful, and always working about. But these intervals were inconstant and short. They were all willing and anxious to have anything done at all that might make her better.

I cannot say that I was very hopeful of any treatment myself, as I was undoubtedly considerably in the dark. As can be seen there was nothing very organically to go upon. There was certainly the distension of the abdomen, but that was clearly only a symptom of some other disease. There was also the dysmenorrhœal pain of which she complained, but that was not particularly excessive, and the diagnosis of ovarian and tubal disease was made more as a tentative or possible condition from the symptom. She was a virgin, and an examination under chloroform in that condition is deceptive unless there is gross organic disease of the appendages.

In any case, she was an exemplary patient while in the Home—had very few attacks of pain—and made few complaints. Of course she was resting all the time, which was very much in her favour.

When she was dismissed on March 12th, she was much better altogether, and I, as well as her parents, had good hope that the improvement would continue. It did so for a few months, and then she became worse than ever. And I am sorry to say more than ever all those about her, with the steadfast exception of her father and mother, reckoned that she was putting it on, that she was not so bad as she pretended to be, that she could help it if she liked, and so on.

Perhaps I, too, had a kind of half idea that there was an element of voluntary deception in the matter, but I did not say so. I am saying so now, because I am so sure now that I was absolutely wrong, that the apparently voluntary part of it was the involuntary automatic connection between her physiological and psychological condition, and that there was no more a separate voluntary action on her part than there is on the part of the governors on an engine, when the safety valve is pressed open by excess of steam.

She was therefore readmitted on May 12th, 1891, and dismissed on the 23rd of the same month.

She was only under observation during that period and although her record of residence was again favourable I made up my mind to advise a major operation if she again relapsed. I did so on grounds which I fully explained. I said that I believed that there was a deep-seated organic disease at the bottom of all her symptoms. That, as she was now suffering from distinct ovarian pains and abdominal tenderness, the most effectual method of dealing with them would be by means of an abdominal section, and then acting according to whatever internal conditions might be found.

She was then dismissed. It was not long till she was worse than ever, and she was re-admitted on November 15th, 1891, for the purpose of major operation.

I am detailing this case at large not because I consider that I had any special credit by it, but because its lessons sank deep into my heart, and because, as I said, it was the first where I had deliberately, after diagnosing a so-called neurasthenic affection, called in the aid of surgery.

The operation was done. I was very anxious not to sterilise the patient if it could be avoided; and examined both ovaries and tubes carefully. Both sides were affected. The ovaries were cystic, and the tubes were inflamed and thickened, the fimbriæ were œdematous. It was difficult to choose between them if one set only was to be removed.

I then discovered that the appendix vermiformis was enlarged, apparently under an acute attack of appendicitis. It was quite loose. That decided me. I removed the appendix and the ovary and tube on that side, and punctured all the cysts I could find in the left ovary. She made a very easy recovery and was better. She went home, and at first I had delightful news. Everything seemed to be going on well. Menstruation had continued at first without pain, and if she had then passed totally from my sight I would have been hugging the delusion that she had been cured.

As it was, however, I learned subsequently that she had relapsed, at first slowly, then more rapidly, till she became as bad as, or worse than, ever, and ultimately died, at no long interval, under the care of Dr. McFarlane, of Busby, I understand.

Now I am sure, having pondered much over this case, that I did too little, and that it is quite possible, had I done more, the ultimate issue would have been different. And what I argue from is this: the uterus itself partook of the general congestion; but it had also the special rigidity to which I have referred so frequently, and while an ordinary metritis may naturally be considered to subside under a simple blood-letting process, this kind of condition, dependent, as I think it is, on immediate or remote nerve irritation, can only be dealt with in a manner that radically deals with the nerves. Hence I think I ought certainly to have removed both uterine appendages completely—not sparing the cornua of the uterus.

At any rate, if I had the same indications now I would carry out the plan as I have stated.

Anthrax in Bradford.

ANOTHER inquest was held last week in Bradford on the body of a man who had died of anthrax contracted in the manipulation of inferior mohair. It transpired that during the preceding fortnight six other men had been away ill, and one of them had since died of the disease. The constant recurrence of this extremely fatal disease affords indisputable evidence of the inadequacy of the precautions at present enjoined, and further measures to protect workpeople are urgently called for.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

CLINICAL EVENING.

MEETING HELD FRIDAY, OCTOBER 24TH, 1902.

MR. HOWARD MARSH, F.R.C.S., President, in the Chair.

PRESSURE PARAPLEGIA SUCCESSFULLY TREATED BY COSTOTRANSVERSECTOMY.

MR. J. JACKSON CLARKE showed a girl, æt. 4, weakly and thin, who was admitted with an angular projection in the upper dorsal region of the spine, and loss of power in the lower extremities. Treated by complete rest in bed and fixation of the spine, abundant food, air, and cod-liver oil for eight months; the paraplegia had, with slight fluctuations, steadily got worse, and was accompanied by marked wasting of the limbs. A skiagram showed a round area of darkness with its centre opposite the fifth dorsal vertebra believed to be tuberculous and inflammatory infiltrations, and the operation described by Ménard in 1894 was carried out on January 15th, 1902. The right transverse process of the fifth dorsal vertebra and the neck and head of the corresponding rib were removed, and some iodoform-glycerine-carbolic emulsion injected. The immediate result of the operation was that the previous limp and powerless condition of the limbs was replaced by a slight degree of spasticity. This passed off in a few days, and the condition was again the same as had been observed before the operation. Seven days after the first operation the track leading to the pre-vertebral tuberculous area was again opened up under an anæsthetic and scraped; this time a tube was inserted so that a little of the emulsion could be injected daily. Again the slight spastic condition showed itself, but this time the voluntary movements improved also, the child at first being afraid to move her limbs owing to the excessive and painful spastic response. The spastic condition soon began to pass away, and the voluntary power steadily increased. The patient has now been running about in a totally normal way for some months. The deformity of the spine has been lessened by the mode of fixation employed.

CONGENITAL SHORTENING OF ONE RECTUS ABDOMINIS MUSCLE.

MR. J. JACKSON CLARKE also showed a girl, æt. 10, who originally presented a congenital shrinkage of the right rectus abdominis muscle. The muscle was divided by open operation, and the previously kyphotic spine was over-extended, and during this proceeding the divided ends of the altered (fibrosed) muscle separated for three inches within the sheath. The gain in mobility of the spine and in respiratory power had been marked.

TWO CASES OF FAMILY PROGRESSIVE SPINAL MUSCULAR ATROPHY (WERDIG-HOFFMANN TYPE).

DR. F. E. BATTEN showed (1) a boy, æt. 7, who was strong and healthy until twelve months of age. From that time onward progressive wasting of the thighs and weakness of the legs was noticed. He talked at eighteen months, and is very intelligent. He was the sixth of eight children. He was unable to rise from chair or ground. Wasted thighs. Weak dorsal muscles. Small trapezius. Wasted upper part. Marked weakness of flexors and extensors of the thigh; weakness of flexors and extensors of the knee. Wasting and weakness below the knee, not nearly so much as above the knee, but still considerable weakness of extensors of foot. Knee-jerks absent. Plantar flexion. No anæsthesia. No reaction to strong faradism in affected muscles. Muscles of arm react well. His sister, æt. 1½, showed wasting of legs first noticed when twelve months old. When six months old was strong, healthy child; she could stand, and walk up to her mother. Since twelve months old the legs have steadily wasted, and now the child is unable to stand, and is so weak that she moves her legs with her hands. *Present Condition.*—Intelligent, well-developed arms, wasted and weak thighs and gluteal muscles. Muscles below the knee fairly good. Knee-jerks absent. No anæsthesia.

CASE OF LEPROSY UNDER TREATMENT.

Dr. T. D. Savill showed a boy, æt. 16, who was born in Demerara, and came to England when eleven years old, suffering from leprosy, which had started at ten years of age with slightly raised erythematous and pigmented patches, most of which were anæsthetic. When last exhibited the patches were no longer raised, but over arms and legs and face were many pigmented, ovoid patches. Both ulnar nerves, and especially the left, were thickened. Under treatment by Chaulmoogra oil all anæsthesia and nerve thickening has gone, and all pigmentation and erythema has disappeared. There only remain slight indications on the face, which are hardly visible to the naked eye.

CASE OF EXTENSIVE WASTING OF THE TYPE OF FACIAL HEMIATROPHY.

Dr. Harry Campbell showed a woman, æt. 26, in whom, since twelve years of age, the right leg began to waste, and the wasting has steadily progressed since. On the inner part of the right thigh just above the knee, and on the dorsum of the right foot in the neighbourhood of the first interosseous space, there is discolouration and pronounced atrophy of skin and subjacent tissues. A similar discolouration, or mottling, is observed in the corresponding regions of the opposite limb. Similar mottled patches, sometimes with decided atrophy of the skin and underlying soft parts, are present in other parts of the body, *e.g.*, on the right upper lip, over the right scapula, and on the left side of the waist. The right eyeball is retracted, and the right pupil smaller than the left: it reacts to light and accommodation, and only slightly dilates under cocaine. Over the right parieto-occipital region the hair comes out readily, and pain is sometimes felt here. The tendon-jerks are active in the lower extremities; a doubtful Babinsky's sign has been obtained in the right foot. Besides the right-sided headache, patient has for the last few years had considerable pain in the right leg above the knee and over the anterior tibial region. There is no anæsthesia, but pronounced hyperæsthesia over atrophied patch on the right foot. The electrical reactions are normal.

A CASE OF LOCOMOTOR ATAXY WITH ATROPHY OF THE BONES OF THE FEET.

Dr. Thos. H. Kellock showed a man, æt. 40, who three years ago began to suffer pain in his feet, and had some ulcers on them, from one of which on the left foot a small piece of bone came away. Up to that time he had noticed nothing wrong with the shape of the feet, but from that time onwards this began to change, and they became shorter and deformed. In March, 1902, when much "run down," he had ulcers in the soles of the feet, and was taken seriously ill with great pain in the abdomen and constant vomiting. This lasted ten days, and after a few weeks he went back to his work (manager at a restaurant), but has had to give this up again recently, as he feels so weak. A truss which he has been wearing for inguinal hernia has caused an unhealthy ulcer over the sacrum. The patient has fairly well-marked symptoms of locomotor ataxy. The feet show old and recent trophic ulcerations, and most of the metatarsal and phalangeal bones appear atrophied and shortened.

DISPLACEMENT OF THE HEART DUE TO LONG-STANDING PLEURISY.

Dr. Raymond Crawfurd showed a girl, æt. 15, who, when eight months old had a severe illness, said to be "dry pleurisy," which left her very thin and weak till three years old. At times the face is distinctly cyanosed, and the finger-tips are a trifle blunt. The left side of the chest is hyper-resonant, and the area of cardiac dulness is absent. Stridor is felt and heard all over this side, gradually diminishing in intensity towards the base. At the level of the fourth rib in front absolute dulness begins, and passes outwards to the level of the sixth dorsal vertebra behind; over this area, particularly behind, are heard cavernous breathing and loud gurgling *rales*. The heart's impulse was best felt in the fifth right interspace in the mid-axillary line.

RECOVERY AFTER REMOVAL OF ADENOMA OF KIDNEY.

Mr. J. D. Malcolm showed a child, æt. 11 years 10½ months, from whom an oval tumour of the right kidney was removed ten years ago, on November 15th, 1892. The growth with kidney measured six inches in length, and was described as a malignant adenoma. The patient shown had had no serious illness, and has enjoyed good health since the operation, but has remained rather paler than her brothers and sisters.

HYPERTROPHIC CIRRHOSIS OF THE LIVER (SYPHILITIC? WITH CHRONIC JAUNDICE AND XANTHOMA.

Dr. F. Parkes Weber showed a woman, æt. 54, who presented great uniform enlargement of the liver which formed a rounded tumour-like projection in the abdomen, rather hard to the touch, and extending into the right iliac fossa. The spleen can be felt moderately enlarged. There is jaundice with a certain amount of chronic pigmentation of the skin, as in all cases of very chronic jaundice, also xanthoma (tolerably symmetrical) of the eyelids, front of face, sides of the neck, flexures of the elbow and finger joints and umbilicus. The enlargement of the abdomen has probably existed for eight or nine years, but has become much more striking during the last two years. The jaundice has apparently only been noticed for about twenty months, and the xanthoma for four months. There is no evidence of alcoholism, but there are scars on the legs almost certainly due to syphilitic gummata. A dragging pain is sometimes felt in the right side, but there is nothing pointing to cholelithiasis. There is no family history of chronic jaundice. The degree of jaundice varies much from time to time. A great improvement has recently taken place in the patient's general condition, independently of any specific treatment, and the jaundice has become very slight. The itching, which is sometimes intolerable, has likewise much diminished. The fæces are well coloured, and the urine contains no bile, though on addition of nitric acid it becomes darker, and then spectroscopic examination shows two absorption bands, apparently corresponding to urobilin and uroroseïn. The patient is now under antisyphilitic treatment. It is probable that the liver disease was started by syphilis, but it is doubtful whether the change in the liver should be regarded itself as chiefly syphilitic, or rather as a form of Hanot's disease started by syphilis, but perhaps in a person predisposed to biliary forms of cirrhosis (cholæmic diathesis of French authors).

A CASE OF HERPES ZOSTER, QUICKLY FOLLOWED BY FACIAL PARALYSIS.

Dr. Stanley Barnes showed a man, æt. 40, an in-patient at the National Hospital, Queen Square. He had never suffered from ear disease, and his previous health was good. On September 30th of this year he was exposed to cold, and next day noticed a few "pimples" on the right side of his neck. By October 3rd the rash was fully out, but he had no pain. He did not feel at all ill, and continued at work, but on October 8th found the right side of his face was paralysed. On admission to hospital next day there was a profuse herpetic rash over the third and fourth cervical distribution on the right side, and this area of skin was slightly analgesic. There was no pain. There was complete right facial palsy, the platysma also being involved. The electrical reactions were normal. Taste was lost on the right side of the tongue, front, and back, but was preserved on the left side. There was some dulling of the sense of hearing, especially of hearing musical notes, on the right side; bone conduction was good, and conversation was easily heard. The membrana tympani was normal, and there was no ear discharge. The general health was quite good. By October 22nd the rash had dried up and the facial paralysis was improving, the frontalis and platysma particularly showing signs of return of voluntary movement. The electrical reactions were still normal. Hearing and taste were quite normal again.

ULCER OF TONGUE.

Dr. McGavin showed a small boy who, when first seen, presented an ulcer on the dorsal surface of the anterior third of the tongue, not indurated, but very hyperæmic, covered with a wash-leather slough, with moderately-enlarged soft glands at the angles of the jaw. He presented no signs of syphilis and there was nothing pointing thereto, no constitutional disturbance and no history of struma. Under iodide of potassium the ulcer had dried up and was rapidly healing.

HARVEIAN SOCIETY OF LONDON.

A clinical meeting of this Society was held on October 16th, Mr. Watson Cheyne, F.R.C.S., President, in the Chair.

Obscure Cutaneous Lesion in an Arthritic Subject.—Dr. A. Morison showed a girl, æt. 8, who was admitted to the Paddington Green Children's Hospital in March with rheumatic arthritis and endocarditis. Shortly after admission she developed a persistent erythematous state of the skin, spreading in ring form and affecting only the trunk. The condition was probably vaso-motor, not parasitic. In May the child was sent to a convalescent home at Slough; whilst there an attack of rheumatic arthritis occurred with a recrudescence both of the endocarditis and surface erythema. The child returned to the hospital with organic mitral reflux. Dr. Morison believed that the endocarditis and vaso-motor skin changes were due to the same blood state or micro-organism, and suggested that rheumatic chorea was probably due to such vaso-motor changes in the cerebral circulation as were visible on the skin. Dr. Morison showed a second case of a boy to illustrate the insidious onset and progress of endocarditis.

Acute Suppuration in Both Knees.—Mr. Raymond Johnson brought forward the case of a boy, æt. 12, who had recovered from acute suppuration in both knee-joints. The source of infection was uncertain, but there had been otorrhœa for two years. The pus from the joints yielded a pure culture of streptococcus pyogenes. The right knee, the first affected, was opened and drained, subsequent incisions being made into abscesses which extended beyond the joint. On account of the unsatisfactory progress of the case he had just decided to amputate when suppuration occurred in the left knee-joint; amputation was deferred, and the left joint was freely opened and drained. After a long period of irregular fever, the patient recovered with free movement in the left knee-joint, and also a fair amount of movement in the right joint. Antistreptococcic serum was used in this case without apparent effect. Short drainage tubes of large calibre were used, the joint was firmly fixed, and passive movement was commenced as the suppuration ceased, and even before the incisions were healed.

Case of Thrombosis (?) of Basilar Vessels.—Dr. L. Guthrie showed a woman, æt. 28, who presented the following symptoms: Dilatation and inaction to light of the left pupil, paresis of left superior rectus, partial anæsthesia of left side of face and neck; tremors of both hands, especially of right, marked Romberg's symptom, and a somewhat staggering gait; exaggeration of knee-jerks, but no ankle clonus, plantar reflexes absent. In August, 1900, she had for the first time an epileptic fit lasting twelve hours, no fits since. For nine months afterwards she had severe headaches and vomiting, usually on getting out of bed. These attacks had now ceased. The symptoms pointed to a lesion in the floor of the aqueduct of Sylvius, affecting the centres for the sphincter pupillæ and of the superior rectus. The other symptoms suggested a lesion of the corpora quadrigemina, probably vascular, and due to thrombosis of the basilar vessels. About three years before the first symptom she suffered from a severe sore throat. The soft palate now showed considerable scarring. Her present condition is probably due to the effects of syphilis.

Dr. Guthrie also showed a woman, æt. 44, with Argyll-Robertson pupils, intense atrophy of the optic discs, loss of knee-jerks, but no other signs of tabes.

Tuberculous Fæcal Fistula of Cæcum.—Mr. Roughton showed a man suffering from a fæcal fistula in connection with tuberculous disease of the cæcum. The fistula was of a year's duration, and resulted from an exploratory operation. Although his general health improved greatly he suffered so much inconvenience from the fæcal discharge that he was compelled to seek further treatment. Mr. Roughton had effected an anastomosis between the ileum of the transverse colon by simple suture. Recovery from the operation was uninterrupted. The fistula was not yet healed, but there was now no fæcal discharge.

Extensive Alopecia.—Dr. Eddowes showed two brothers, who occupied the same bed; the younger having almost total alopecia of nine years' duration. The elder, æt. 30, having three round patches on the scalp. The most recent patch, when pressed upon, showed active seborrhœa. Microscopic examination of hairs from both patients presented exactly the same kind of organisms, and pointed not only to the contagious nature of the disease, but showed how the hair died, and how the organisms rendered the hair brittle, and produced the well-known club-shaped stumps. The organism was described as occupying a position between cocci and the fungus of ringworm. It might be termed a bottle bacillus (Unna). He had no doubt about the infective nature of this particular form of alopecia.

Dr. Cautley, Dr. Sutherland, Dr. W. J. Harris, Mr. Watson Cheyne, Mr. T. C. English, and Mr. Jaffrey took part in the discussion of the cases.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Meeting held October 17th.

Dr. G. A. Sutherland in the Chair.

Mr. W. M. Burgess (Harlesden) showed a boy, æt. 4½, who had been treated for a capillary nævus on the left side of the neck by nitric acid and by the actual cautery.

Mr. Francis Jaffrey preferred excision as a treatment for nævi, unless they were situated round the orifices.

Mr. Walter Edmunds relied upon the electric point for their treatment on the face, and considered that Mr. Burgess's result was good.

Mr. Albert Carless also thought the result satisfactory, but he preferred excision. He called attention to nævi which had been left alone and which had remained quiescent for years, but which suddenly burst into activity and became almost angio-sarcomatous.

Dr. C. W. Chapman spoke, and Mr. Burgess replied.

Dr. E. Cautley showed a moderately rickety boy, æt. 13 months, with great enlargement of the spleen and some enlargement of the liver. Leucocytosis was a feature of the case. Five weeks of hospital treatment failed to benefit him. He was discharged and quickly readmitted with numerous petechial hæmorrhages, and numerous myelocytes were found in the blood. He improved and was discharged in six weeks' time. When shown, the spleen was still very large, but he was not anæmic.

Dr. R. Hutchison thought the case must be placed in that group of anæmias associated with splenic enlargement, which was quite peculiar to children, and which might be termed the splenic anæmias of infancy. He had never seen more than 10 per cent. to 13 per cent. of myelocytes in the blood, and when there were a large number of these corpuscles the cases fared badly. Microscopically, as far as his experience carried him, all that could be seen was a general increase of the fibrous tissue, a condition common to many splenic disorders.

Dr. A. E. Sansom said there must be a cause for the condition, but it was a very subtle one. Evidently the child had taken some poison into his system which had produced what almost might be called "a malarial intoxication."

Dr. C. W. Chapman asked whether these cases were more prevalent among the poor than the rich.

The Chairman (Dr. G.A. Sutherland) inquired as to the prognosis, which he believed to be good in the absence of some intercurrent complaint to which such cases were liable. He was of Dr. Sansom's opinion that some poison was absorbed into the system which produced the ill effects.

Dr. Cautley, in reply, said in his experience the prognosis was good. Cases which succumbed nearly always had some other associated ailment, often tuberculosis. His case showed, he thought, that numerous myelocytes did not necessarily indicate a fatal prognosis.

Dr. Leonard Guthrie showed an infant, four months old, who suffered from dilatation of the stomach, which, he thought, was due to pyloric obstruction. The symptoms began at six weeks old with obstinate constipation and incessant vomiting, which latter had now ceased. The stomach was greatly enlarged, its lower margin extending two inches below the umbilicus, and it held fourteen ounces of fluid without causing sickness. Peristaltic waves passed across the epigastrium from left to right. The symptoms had been temporarily relieved by lavage, but now it was thought necessary to resort to an operation to obtain permanent benefit.

Dr. Cautley thought it would be interesting if Dr. Guthrie could rear the child without an operation. He suggested that he should make a further trial of washing out the stomach and prescribe a well-regulated dietary, and failing to benefit the child by these measures an incision might be made. Recently two cases under his care had been successfully treated by pyloro-plasty.

Dr. H. J. Simson narrated a case with symptoms typical of pyloric obstruction, which disappeared when a suitable diet was ordered, and the peristaltic movements of the stomach previously in evidence ceased to be noticed.

Dr. A. H. Sanson thought it an excellent case for surgical interference.

Mr. A. H. Tubby deprecated gastro-jejunostomy, and advocated pyloro-plasty.

Dr. C. W. Chapman thought that an exploratory operation could do no harm, and Dr. D. J. Armour said he did not see how any treatment short of an operation could benefit the child if it were a case of pyloric obstruction.

The Chairman (Dr. G. A. Sutherland) did not think the peristaltic waves pointed entirely to pyloric obstruction, and suggested that there was possibly some obstruction lower down.

Dr. Guthrie, in reply, said his original impression was that of Dr. Sutherland, but frequent subsequent examinations had convinced him that the peristaltic waves originated in the stomach and not in the bowels. He considered he had given careful dieting a fair trial, and he was now inclined to ask a surgical friend to assist him, and he proposed to leave the methods of procedure in the hands of the surgeon.

Dr. E. Cautley showed a girl, æt. 15 months, who had been under his care for hydrocephalus since the age of eight months, which had been arrested by repeated lumbar puncture. The hydrocephalus was secondary to basal meningitis. In all, thirty-five ounces of cerebro-spinal fluid were drawn off by repeated tappings, each being followed by a gain in weight and marked improvement of the general health. Although the hydrocephalus had been arrested the child was blind and lacking of intelligence.

Dr. R. Hutchison said lumbar puncture was recommended in America for diagnostic purposes, as well as being a therapeutic measure. He had tried it, and his results had been much more disappointing. In two children fatal collapse occurred. In resorting to permanent drainage in the lumbar region there was danger of direct damage to the brain. If tapping could be commenced earlier the blindness and imbecility might be prevented.

Dr. White narrated the methods he had adopted to draw off the fluid from Dr. Cautley's case.

The Chairman (Dr. G. A. Sutherland) mentioned that the treatment had been abandoned in America and Germany. He called attention to the closure of communication between the ventricles of the brain and the spinal meninges in sequence to posterior basic meningitis. He did not intend to try puncture. He had suffered a similar experience to that narrated by Dr. Hutchison in the way of sudden death following the operation.

Dr. Cautley, in reply, thought the treatment he had adopted was likely to be successful in only a few cases.

France.

[From our own Correspondent.]

Paris, October 26th, 1902.

Surgery of the Heart.

At the meeting of the French Surgical Congress, M. Terrier read a paper on wounds of the heart and the pericardium which he said were met with under three distinct forms. (1) The wound involves both the heart and the pericardium; (2), it involves only the heart, leaving the pericardium intact; (3), the lesion is in the pericardium alone.

The method adopted for opening the thoracic wall varied with the operator, but that to which he gave the preference was thoracotomy by means of an osteo-muculo-cutaneous flap.

Foreign bodies of the heart should be studied with the wounds of that organ; needles, on account of their frequency, constitute the most interesting group. The relative innocuity of punctures made into the cardiac cavities might make one believe that the introduction of a needle into the heart could have no grave consequences; such is not the case, as, according to the statistics of M. Loison, of twenty-three cases, fourteen terminated fatally, or a mortality of 60·8 per cent. The gravity of these accidents arises from the fact that the eye of the needle remains in the thoracic wall while the point is directed towards the heart, which, from its mobility, produces lesions in every direction. Consequently an accident of this kind should be always attended to and the needle extracted as soon as possible. When the needle has gone out of sight it is better to open the wall than to endeavour to reach it through an incision over the point of penetration. The radiograph is of great utility in such cases.

M. Faure said he had practised drainage of the pericardium on a patient in June last. It was the case of a man who presented all the signs of an enormous effusion in the pericardium with compression of the heart, oppression, fever, and a bad condition generally.

The incision of the pericardium gave issue to a quart of liquid, and a drain was placed. Up to the fifth day not much change was evident except that the oppression had ceased and the heart regained its rhythm; but from that day a great improvement took place, and after removing the drain the wound was allowed to cicatrise. Unfortunately, after a few days, the condition of the patient became again alarming, and over a pint of serum was drawn off, and finally, the wound refusing to heal, gave issue to purulent and fetid liquid, and the man succumbed from cachexia. The autopsy showed that it was a case of tuberculous pericarditis. But the case was interesting in the fact of the extraordinary tolerance of the heart which continued during a month to beat in an open and infected pericardium.

A Predisposing Sign of Pulmonary Consumption.

Dr. Molle, of Aubenas, has published an article in one of the provincial medical journals on the frequency of a souffle in the femoral vein in anæmia of young boys at the age of puberty. The souffle is to be found exclusively in these veins and reveals a chlorotic condition, which demands an appropriate treatment. Continuing his researches in this direction he arrived at the conclusion that the same phenomenon constituted a certain predisposition to pulmonary consumption, and cited several cases of young men about to be drafted into the Army, and in whom he had discovered this sign and who, after spending some months in the Service, were sent home with developed consumption.

An Easy Method of Passing the Stomach Tube.

Everyone knows how difficult it is sometimes for a patient or for a medical attendant to pass a stomach tube. Some patients, it is true, "swallow" it after a little practice quite easily, while others find it absolutely impossible, and most likely belong to the same class who cannot swallow pills. To obviate the difficulty and to conquer the nervous contraction of the pharynx, an American *confrère* advised refrigeration of the end of the tube by chloride of ethyl, but Dr. Montagnon, of St. Etienne, adopts a much simpler method, and which succeeds in every case. He gets the patient to fill his mouth with water, and then slips in the tube, rapidly passing through the water to the pharynx; at this moment the patient makes a motion of deglutition to swallow the water, and the tube is carried down with it; the remainder of the operation is easy.

Germany.

[from our own correspondent.]

Berlin, October 25th, 1902.

Although so much has been written on

Surgical Shock,

an account of some recent observations recorded by Dr. D'Anna in the *D. Med. Zeit.* may not be without interest. He gave an account of five cases in which the symptomatology was specially noted. Paleness of the face, slowing of pulse, lowering of temperature, cardiac weakness, and diminished sensibility were never absent, but the condition of stupor mentioned by most authors was sometimes absent; on the contrary, he sometimes observed violent agitation. Another symptom which was not constant was the involuntary evacuation from the bladder and bowels. Sometimes there was complete anuria or albuminuria. A symptom that, in the opinion of the author, is of the gravest import as regards prognosis, was singultus. He is of opinion that so long as this symptom is absent there may be some hope of saving the patient, but that this hope is cut off so soon as singultus sets in. If there is a question of performing an operation in a patient already suffering from shock he is of opinion that such an operation is permissible so long as no hiccough is present.

The same journal contains an account of a case of

Pyelitis Occurring at the End of Pregnancy

reported by Dr. M. Loeb. The patient, previously healthy, and who had had three children previously, and who expected her confinement in a few days, was attacked suddenly with a rigor, and subsequent fever, with vomiting. She had had a slight pain in the left flank before this. The rigor returned the following day, but not the day after, although the temperature rose to 39·2° C. The evening of the next day she gave birth to a strong vigorous child. The following morning she felt well, but in the afternoon she had a violent rigor lasting half an hour. The temperature was now 41° C. The patient complained of shortness of breath. She became delirious, and could scarcely be kept in bed. After cold affusion and a morphia injection she became quieter, but became restless again in an hour and required a second dose of morphia. Urine was now withdrawn with a catheter, and it contained albumen, so that eclampsia was suspected. This thought was abandoned, however, on the urine being examined with the microscope. It was now found to contain quantities of pus cells, epithelial *débris* and casts which rendered a diagnosis of pyelitis certain. Against the assumption of eclampsia were the high fever and delirium preceding the spasms. No clonic spasms attended the first attack, and the patient recovered completely.

The *Baktirsch Wratsch*, 5/1902, contains notes of a case of

Dermoid of the Bladder

by Dr. A. T. Bagaswski. The patient, a woman, æt. 33, was admitted into hospital complaining of pain during micturition. She stated that she had been eight years ill, and that she has been constantly treated for catarrh of the bladder without success. Examination revealed nothing abnormal externally except that the urinary meatus was slightly swollen. The introduction of the catheter was very painful. No calculi could be felt. On bimanual examination a hard body was felt on the floor of the bladder. The urine was turbid with an ammoniacal odour and contained pus; it was alkaline, sp. gr. 1025, and it contained some albumen. The deposits contained urate of ammonia, uric and hippuric acids and blood corpuscles, bladder epithelium, but no cylinders. On washing out the bladder three small-pointed calculi escaped. The treatment that followed was without result. Chloroform was now given and the bladder explored with the finger. A pear-shaped tumour was found on the floor of the bladder, growing from a slender stalk. The tumour was covered with hairs, and small calculi were seated on the ends of these. The tumour was removed and the bladder carefully washed out with hot boracic solution. For the first two days the catheter had to be used, as the urine was bloody and contained clots, and the bladder was washed out after each catheterisation. Internally salol 0·6 grms. and Vichy water were given. Externally, absolute rest and ice over the abdomen. The patient was quite well by the tenth day. The tumour proved to be a true dermoid with skin, hair, and teeth. It weighed twelve grammes.

The Bactericide Action of Soaps.

The *Archiv. f. Hug.* contains an account of this subject by Dr. Konradi. The author speaks of the very different opinions prevalent on the matter which render an attempt to reconcile them desirable. The author examined resorcin soap (5 per cent. resorcin and 2 per cent. glycerin), and found a marked power of resisting the development of bacteria; agar or gelatin containing 1 in 100,000 of the soap constantly remained sterile after inoculation. Anthrax spores were killed in a solution of 1 in 1,000 in four hours at a temperature of 37° C., and in twenty-four hours at the temperature of the room. The soap was not, however, a disinfectant. Further experiments showed that only soaps that contain odoriferous substances (terpineol, tanilline, cumanine, heliotropine) had any bactericide action. Inquiry showed that terpineol was especially poisonous.

Austria.

[From our own Correspondent.]

Vienna, October 25th, 1902.

Treatment of Tuberculosis.

At the Bohemian Congress Teuoer described his method of treating cases of tuberculosis in hospital instead of in sanatoria, which can be done at a comparatively small cost. He has caused to be erected a special ward, sheltered by the main building on every side except the south, which is exposed and open. In this ward the patient resides day and night in the summer time, but in the winter by day only, from six in the morning to six at night. Before exposure the body is well sponged and rubbed with cold water to harden the patient for the open air. Meals are given frequently, milk being preferred, but no alcohol, three litres being the usual quantity required—6·6 lbs. equals 105·6 ozs· or 5¼ pints, which is equal to about 15 ozs. of dry solids in twenty-four hours.

The patients usually put on 15 kilos, or 30 lbs. weight in a short time with this diet and suitable personal hygiene.

Drugs are of less consequence, although creosote and pyramidon may be given to reduce fever, while codeine and heroine may be used to quiet the cough.

Of fifty-five treated in this way he had fifteen who seemed at the present time to be perfectly well; twenty-one were greatly improved, sixteen put on flesh, and three died.

Hetol injections given after Landerer's methods are also of use, but Teuner declared that he had never seen such results as Landerer claimed to have obtained therewith.

Intra-ligamentous Fibroma.

Wenzel Pit'ha related a case of intra-ligamentous tumour complicating pregnancy. The patient was æt. 41, and had not been pregnant for the previous twenty years. Recently a tumour commenced to form in the right groin, and gradually extended into the abdomen. From the history and examination the swelling was diagnosed to be an intra-ligamentous tumour. Total extirpation of the uterus proved that in addition to the tumour that filled the broad ligament the uterus contained a fœtus in the fifth month of gestation. The uterus weighed 6½ kilos, or 14·3 lbs., and the cardiac sounds could be heard for more than an hour after removal.

Hansman related a similar instance in a school teacher, æt. 39, with all the symptoms of a fibroma of the ligament. Pregnancy had never entered into their calculations till the uterus was removed, when it was found to contain a four months' child.

Audition Olorée.

Chalupecky brought the whole subject of audition olorée before the meeting as one of those peculiar sensations belonging to the secondary class of motor movements, or a combination of hearing and seeing sensations on the same nerve, acoustic perceptions producing at the same time a particular and distinct colour.

He presented a young man who saw a different colour according to the sound that was produced in the scale. The vocal sounds, when expressing figures, days of the week, or the same tone by a bell, produced the same colour. He thought this was a congenital affection presiding in the cortical part of the brain as a hyperæsthetic condition just as temperament or genius was a neurotic implantation. We have similar conditions produced artificially with drugs such as santonin, Indian hemp—audition olorée; alcohol—acoustic hallucination by tapping the skin. In his opinion audition olorée is simply a congenital hyperæsthesia of the grey cortex of the brain.

Pemphigus Vegetans.

Samberger showed a man, æt. 59, who had previously to the present illness been always healthy and strong. The affection commenced as a simple condylomatous efflorescence rising from denuded parts of the Malphigian layer; later on vesicles appeared giving the present appearance of pemphigus foliaceus. This case supports Kaposi's theory that pemphigus vegetans is not a distinct disease, but only secondary to others.

Toxic Dermatitis.

Samberger next showed cases of dermatitis produced by the toxine from plants or from the insects found on them, such as chrysanthemum, &c. That caused by the plant *Primulio obconia* is very common. He was in favour of the theory that the dermatitis was due to the direct irritation of the skin by small particles of the secretion of the plant that was present on every part of it appearing above ground.

Rhino-Scleromo.

Kutvirt brought forward a young woman, æt. 38, who had always been healthy and came of a healthy family. Three years ago she began to sneeze, with running at the nose, which finally became blocked. There was no evidence of syphilis or injury to cause the trouble. The upper lip and external part of nose are quite normal. Within the orifice of the nasal cavity the hard tumour commenced and extended back to the choana posteriorly, while the mucosa of the pharynx was greatly atrophied. Microscopical examination revealed a scleromatous growth. The patient lived in an upland district 730 mètres above sea level, where only a small streamlet ran.

The Operating Theatres.

NORTH-WEST LONDON HOSPITAL.

Old Tuberculous Disease of Ankle-Joint.—Mr. **Mayo Collier** operated on a child, the subject of old tuberculous disease of the ankle-joint. The treatment of rest in splints and the opening of abscess formations had been adopted without much benefit. A sinus now led down to the ankle-joint in front and two old scars existed over the site of each malleolus indicating a previous operation. The disease was apparently limited to the ankle joint, and the other joints of the tarsus moved freely and were apparently quite unaffected. Under these circumstances Mr. Collier thought that in resecting the ankle-joint the whole of the diseased tissues should be removed once and for all, and no particle of diseased synovial membrane or bone left to reinfect the other parts and continue the disease. The ordinary operation for excision of the ankle-joint by longitudinal incision over each malleolus affording an incomplete inspection of the parts, Mr. Collier adopted a more extensive and troublesome procedure of dividing the whole of the tissues, tendons, nerves, and vessels down to the capsule in front of the joint. By dividing the anterior middle portions of the lateral ligaments, a complete view could be obtained of the entire lining of the ankle-joint. The skin incision was carried by a curved sweep from the apex of one malleolus to the other, so as to extend a good inch below the line of the ankle-joint. At the point of division of the tendons and nerves a fine silk thread was passed through each to more easily identify the same and prevent retraction and afford a greater facility for reuniting the several parts at the completion of the operation. Extensive disease of the tibial aspect of the ankle-joint was discovered, as well as much thickening of the synovial membrane of the posterior lateral aspect of the joint. The whole of the diseased tissues in the lower epiphysis of the tibia were removed down to the epiphyseal cartilage, and the diseased synovial membrane obliterated, and the joint closed by deep and superficial sutures. Each cut tendon was readjusted as well as the anterior tibial nerve, and the foot carefully adjusted on a splint, with the foot piece at right angles. Mr. Collier contrasted the present method of conservative surgery with those of the past. Not many years ago this foot would have been condemned to amputation or excision with all its drawbacks, but now the practice of opening a joint and removing only the diseased tissues with a good expectation of preserving fair motion and use, applies to most joints of the body. The little manipulation of securing the tendons and nerve before division so as to prevent their retraction subsequent to identification and adjustment would considerably lessen the task of completing the operation. In this case one would expect union by first intention, good motion at the ankle-joint, and no loss of power or sensation.

Tuberculous Ganglion of Wrigt.—The same surgeon also had brought into the theatre a young man, æt. 20, the subject of a previous operation on the ankle-joint, now complaining of a large compound ganglion of right forearm of some eighteen months' standing, which had slowly been getting worse. The affection of the sheath was seriously impairing the use of the forearm, and some radical measure of relief was evidently called for. The disease was probably tuberculous, from the amount of thickening of the parts and its association with previous tuberculous disease of the ankle-joint. In this case, as in the last, a partial operation would be worse than useless, so Mr. Collier determined to expose the whole length of the sac by dividing the anterior annular ligament. This was done by a long incision from the root of the fingers to some four inches above the wrist-joint. The sac was found much thickened and contained the usual melon seed bodies. Each tendon was stripped of its covering and the whole sac removed by a careful but tedious dissection. The anterior annular ligament was readjusted and the wound closed. Mr. Collier said previous experience of this operation had not always been satisfactory; the result in some cases being a return of the trouble and in others a stiff and more or less useless hand. The method of opening the sheath, emptying its contents and applying irritants with a view to its obliteration, was seldom in Mr. Collier's experience attended with success. The more radical operation of complete excision was in the highest degree satisfactory. In a recent case the wound healed by first intention, there was no stiffness of the fingers and there remained considerable power of flexing the wrist and closing the hand.

In this case a similar result was to be expected.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 29, 1902.

COSMOPOLITANISM IN MEDICINE.

In the address recently delivered by Dr. Osler before the Canadian Medical Association on "Chauvinism in Medicine," we are reminded of the fact that although science knows no frontiers, medical science still preserves traces of these archaic lines of demarcation. There is a chauvinism of schools as well as a chauvinism of nationality, and both are equally detrimental to the breadth of thought which is necessary to its highest development. The dissemination of knowledge by means of the medical journals has unquestionably done something to "disperse" this intellectual neoplasm, but unfortunately it is to be feared that much of the good work done by them falls on sterile soil. There is a limit to the energies of the individual practitioner, and in but too many instances by the time he has got through his day's work he has neither time nor inclination to maintain himself *au courant* of the progress of medicine in other countries than his own, even if he contrive to devote some spare moments to see how his own medical world wags. The best, if indeed not the only, means of cultivating breadth of views is to visit the various shrines of learning, a privilege which is at present confined to the comparatively few, partly for financial reasons and partly no doubt on account of the difficulties interposed by differences of language. American physicians, probably more than any other category of medical men, appreciate the advantages to be derived from this form of "Weltcultur." They are to be met with at every important European centre of medical teaching, and they evince the greatest desire to become conversant with the methods and ideas there current. It is possible that many, or at any rate some, of them return with an exaggerated notion of their acquisitions, but it cannot be denied that the influence of the teaching must be to facilitate a better grasp of their subjects. French and German physicians are so convinced of the respective and superlative excellence of their respective schools that but exceptionally do they think it worth while to stray outside the institutions of their native lands. Nor can it be truthfully said that English physicians avail themselves of the facilities offered by the geographical situation of their island to anything like the extent that they ought. Year by year, however, the proportion of Englishmen who complete their studies abroad is increasing, especially among those who aim at departments of practice superior to that of the drudgery of their calling. Medical students may be divided, roughly speaking, into two categories, viz., those whose intellectual horizon is limited by the acquisition of sufficient knowledge to enable them to obtain the right to practise and those who view a medical degree merely as a step in the direction of that higher standard of culture and skill which makes for success in the scientific practice of medicine. It is to the latter class that we look for the solution of the many obscure questions which are the opprobrium of the science of medicine, and it is by the concerted labours of observers all over the world that the veil of ignorance will little by little be drawn aside and that we shall let in the light upon morbid processes which have hitherto baffled investigation. Direct contact with workers in other countries than our own begets a sympathy and community of views which can never result from the mere glimpses of their work, which is all that medical journalism can give. The International Congresses, although in some respects they have disappointed the expectations of their organisers, have at any rate the merit of having brought together earnest labourers in the field of clinical and experimental research who would otherwise not have met. Such meetings tend to break down international jealousies, substituting a friendly rivalry in the investigation of natural phenomena, which is of the happiest augury for the future of science and of mankind.

RATE-PAID MIDDLE-CLASS ASYLUMS.

The treatment of lunacy constitutes a matter of prime importance to the community of every civilised state, not less from the curative than from the preventive points of view. There can be no question that great as the progress has been in the past as regards this special study, there still remains a wide field of conquest. The more exact education of the public and of the medical profession, for instance, in the recognition of the earliest signs and symptoms of mental change is a necessary precedent to a higher standard of successful treatment of insanity. Improved diagnosis, however, is only half the battle, and its lessons will be wasted unless ample provision be made for the accommodation of patients at all stages of their complaint. The attempt to meet this logical outcome of the scientific and humane tendencies of the age has led to the establishment of public asylums for all grades of pauper lunatics in every part of the United Kingdom. In these institutions the most modern medical and nursing skill has been combined with housing and general environment of an exceedingly high standard. In England and Wales there are no less than 110,700 notified lunatics, who have been classified by the Commissioners of Lunacy into eight groups, namely, (1) inmates of county and borough asylums; (2) of registered hospitals; (3) of licensed houses; (4) of naval and military hospitals; (5) of criminal lunatic asylums; (6) of workhouses and Metropolitan District asylums; and (7) private single patients; (8) outdoor paupers. The asylum accommodation, however, hitherto forthcoming to meet the demands of that classification has failed to provide for middle-class patients of small means. As a result, the friends of insane persons of that class have been compelled to turn to the shelter of the Poor-law lunatic asylums, where a small payment has, where possible, been made to cover the cost of maintenance. Such a system, clearly enough, is not calculated to bring about the cure of persons who have been reared amid the comfortable surroundings of middle-class position and suddenly plunged into the atmosphere of a pauper institution. So long ago as 1890 powers were conferred on local authorities to furnish accommodation out of the rates for the middle-class insane able to pay the cost of maintenance. It has been left for the West Riding of Yorkshire, so long the centre of enlightened lunacy reforms, to erect the first rate-built private asylum in the United Kingdom. The advantages of this institution it would be difficult to over-estimate. The ever-increasing pressure on pauper asylums will be relieved by the removal of a class of patients who will be placed under far better conditions as regards their chances of cure. The minimum charge for treatment at the new asylum will be 25s. a week, a sum which should leave a small margin of profit. The experiment is one that will be followed with interest by all who are concerned in the many important scientific and social aspects of lunacy. The example thereby furnished is certain to be followed shortly in other parts of the country; indeed, a movement of the kind is already on foot in a southern county of England. Meanwhile, we offer Yorkshire our sincere congratulations on its advanced position with regard to the most recent departure in the enlightened treatment of our insane population.

Mr. Frank B. Thornton, M.B., B.S., London, has been elected honorary physician to the Derbyshire Royal Infirmary.

Notes on Current Topics.

Social Honours in Medicine.

DOUBTLESS the status of the medical profession is steadily advancing throughout the world. In the United Kingdom it is still true that titular honours, especially in the higher grades, are reserved for the Army, the Navy, the Church, the Civil and Parliamentary Services, and for the wealthy upper ten generally. Literature has been honoured in a few instances during the past few generations in the persons of a few distinguished literary men who have been raised to the peerage. Medicine has thus far been recognised in that way by the admission of its single peer, Lord Lister, as a member of the Privy Council. If the conferring of titles be of any real value to the community at large it could hardly be exercised in a more distinguished manner than by ennobling the greatest figure that has hitherto stood out prominently in the history of medicine. It may be doubted, however, if the name of Lister will be rendered more revered or illustrious by the addition of a title. The world has always called Bacon by that early surname, and has refused to apply to him his title of Lord St. Albans. The late W. E. Gladstone chose to go down to posterity without any title of nobility. On the whole, medicine would probably preserve its traditions with infinitely greater grace and dignity by declining titular honours.

Popular Support of an Unqualified Practitioner.

A PUBLIC meeting, held under the auspices of the Peoples' Medical Defence Union, was held at Birkenhead a few days since to protest against the action of the coroner in deciding to hold inquests upon all cases in which an unregistered medical practitioner had been in attendance. Technically, of course, such deaths are uncertified, and, although it is not exactly law, we were certainly under the impression that coroners exercised a wise discretion when they made a practice of inquiring closely into the circumstances. If the report before us, from the *Liverpool Daily Courier*, is to be believed, the Home Secretary considers that by so doing the coroner would be exceeding his duty, a strange position for a Minister of the Crown to take, since it constitutes a direct recognition and encouragement of irregular medical practice. Moreover, the Registrar-General seems to have "climbed down," since he has decided to withdraw the special instructions which he had given in this connection. All this fuss has been caused by a certain Mr. Pleavin, who claims to hold an American diploma and has practised extensively on the strength thereof. The curious pass to which matters have come only emphasises the urgent necessity for a remodelling of the laws bearing on death registration. To employ a colloquial phrase, "We don't know where we are." This Mr. Pleavin infringes the Apothecaries Act every time he supplies a patient of his with medicine; he has, so far as we are aware, never been called upon to prove that he holds a reputable medical diploma, even of American origin, and as he is necessarily unregistered he possesses no status as a medical man. But what of this if he be privileged to act as though he were an ordinary registered practitioner? Truly our laws are chaos!

The Traffic in Putrid Meat.

THE occasional detection and punishment of a dealer in putrid meat really affords no adequate safeguard against this disgusting and dangerous traffic. Moreover, it is so profitable that the comparatively trifling fines which are imposed can in no sense act as deterrents. Last week an exceptionally revolting case was tried at the Clerkenwell Police Court, the prisoner having already been sentenced to a term of imprisonment for a similar offence, yet all the magistrate could, or did, do was to send him to prison for four months! Under the circumstances the penalty is miserably inadequate. A person may get that for picking pockets or some other comparatively venial offence—venial, that is, compared with the scattering of disease and death which is deliberately compassed by the vendor in rotten meat. The penal laws dealing with this class of offence urgently require revision. A man who sells chicory for coffee is as much a thief as one who deftly abstracts one's watch, and when his fraud also entails certain and grave injury to health a double penalty should be inflicted, one for the offence against property and the other for the offence against the person. Moreover, there is no valid reason why even first offenders should be let off with a fine. Their fraud is one of the most deliberate kind and is inspired by the most sordid motives. The law is inadequate, and magistrates for some reason are lamentably indulgent, with the result that such frauds, being difficult to detect, are rampant, and are likely to remain so.

The Service of St. Luke.

SEVERAL hundred practitioners, many of them arrayed in University gowns, were present at the annual medical service of St. Paul's Cathedral, arranged by the Guild of St. Luke. They occupied reserved seats under the dome, the transepts and the nave being filled by a vast congregation. The service was an impressive one, and there were seven hymns, in addition to the anthem, which were rendered with much taste and feeling. The choir of 250 voices consisted of members of the London Gregorian Choral Association, with Dr. Warwick Jordan at the organ. The anthem, "Hail, Gladdening Light," was conducted by the composer, Sir George Martin. The selection of the Bishop of Kensington as the preacher was fully justified. Taking as his text the words, "When I thought to know this, it was too painful for me, until I went into the sanctuary of God," he dwelt on the problems which confronted society in all ages, and which perplex men still. Incidentally he mentioned that in the portion of the diocese of London in which he labours, reaching from Oxford

Street to Hounslow in one direction, and from Uxbridge to Fulham in the other, there are no fewer than twenty hospitals and infirmaries. The Bishop made an appeal for a liberal offertory in support of the erection of a new college for the training of medical missionaries.

A New Sign of Paralysis of the Intestines.

At the recent meeting of the Canadian Medical Association, a new sign produced by paralysis of the bowel was described by Dr. G. Peters, of Toronto. Put shortly, it consists in increased transmission of respiratory and cardiac sounds along the intestines, as determined by auscultation of the abdomen. Dr. Peters terms his sign increased telephonic properties of the inflamed abdomen. His explanation of it, that whereas in the healthy bowel intestinal gas is retained in certain well-defined and circumscribed departments, each constituting a complete retainer in itself, in the paralysed bowel, by reason of its flaccid and atonic condition, the entire intestine is, acoustically considered, a continuous column of gas, which thus acts "on the precise principle of a stethoscope," the rigid abdominal walls acting as a sounding board. He further considers that the more well marked the sign the worse the prognosis, as the degree of paralysis is presumably greater. The increase in transmission of sound is a very natural condition to find in intestinal paralysis, but it is, perhaps, doubtful whether it is the result of the presence of a continuous column of air or gas so much as of the cessation of peristalsis. When the intestines are in their normal condition they do not constitute a favourable medium for the transmission of sound, in consequence of the presence of peristaltic movement, but once the latter has ceased the intestines become a more or less uniform and homogeneous mass through which sounds are readily transmitted.

Fallacies in Ordinary Tests for Glycosuria.

Most physicians who examine candidates for life assurance have from time to time met patients whose urine gave a positive result for sugar with Trommer's or Fehling's tests, but who nevertheless appeared to be, and, in fact, were, in excellent health. This being the case, it is always well to bear in mind that there are other substances besides sugar which may occur in urine, causing the copper reduction, or some colour-changes which are liable to be confused with it, and never to remain satisfied without the application of further tests. The most important of these "complicating" bodies are glyceronic acid and pyrocatechin (causing "alkaptonuria"), both of which give true copper reduction, while neither responds to the fermentation test. Pyrocatechin, it seems, is present even in healthy urine in small quantities, but is considerably increased by a proteid diet. Glycuronic compounds occur sometimes in healthy urine, but in particular after the use of various aromatic drugs, such as camphor and turpentine, and in some infectious fevers. Other substances which may under certain conditions cause colour-changes in the application of the copper test for sugar are uric acid and creatinin, though the probability of their doing so is small.

Clergyman's Sore Throat.

Sir Squire Bancroft has been preaching to the clergy from the text: "Happy are they that bear their detractions, and can put them to mending"—an excellent text which, however, does not come from the Scriptures, but from "Much Ado About Nothing." The eminent actor has been wise in giving clergymen some advice on the hygiene of the voice. Many preachers, he contended, spoke so entirely from the head or throat, instead of from the chest, that they fell victims to a complaint known as "clergyman's sore throat." Sir Squire has never heard of "actor's sore throat." The peroration to this remarkable, but in many ways admirable, sermon took the form of a paraphrase of Shakespeare: "Oh, there be preachers that I have heard preach—and heard others praise, and that highly—not to speak it profanely, who neither had the accent of Christian, pagan, nor man, they imitated humanity so admirably. O, reform it altogether." There is no doubt if preachers could be induced to use their voices aright they would save both themselves and their hearers much suffering—and would relieve medical men of prescribing "rest" to many a troublesome and irritable patient.

The Depopulation of Ireland.

The "Irish Question," which, like the poor, is ever with us, is peculiarly many-sided. The recently issued report on the census returns is full of material deserving of close consideration. The population of the whole country is given as 4,458,775. The Dublin district numbers 382,471. During the last decennium, as in each of the five preceding intercensal periods, there has been a decline. The number of lunatics returned in 1901 was nearly quadruple the number in 1851. In all the provinces the number of the Irish-speaking population has diminished. The number of Irish who left the country during the ten years ending March 31, 1901, with the intention of settling elsewhere, was 200,125 males and 230,868 females. We venture to think that even Mr. Wells, in his studies on "Mankind in the Making," must find in such returns "anticipations" which are anything but rosy.

The "Evils" of Fresh Air.

A lengthy and, in many ways, foolish discussion is finding opportunity for expression in the public Press on the supposed absurdities of the present agitation for pure air. Nurses are expressing opinions with respect to the suffering of patients in hospitals from too much air; chaplains are joining in with remarks on the production of pneumonia from too widely opened windows; irresponsible members of the public are plunging into the dispute with an ignorance of hygienic principles and practice that only too clearly indicates the inertia to be overcome if effective progress is to be maintained in regard to sanitary reform. We do not deny that discomfort may arise from "draughts," or that climatic conditions in this country often render convenient access to pure air difficult, but the remarkable evidence afforded by life at a modern sanatorium supplies the best reply to these grumblers regarding the danger of fresh air to the sick and the risk of night air to the delicate. The fact is our habits of life, especially in towns, have for so long been lacking in hygienic requirements that the sudden return to "natural" principles is causing difficulty and serious perplexity to many good folk unable to distinguish between "morbid" and "normal."

The Preservation of Infant Life.

Attention has recently been focussed on the appalling infant mortality occurring in many urban districts. Dr. T. Orme Dudfield, the Medical Officer of Health for Kensington, has just completed an important investigation into this matter as represented in the important centre with the health of which he is concerned. The average infant mortality in Kensington is 161 per 1,000, but in special areas it was as high as 447. As might be expected, a large proportion were deprived the advantages of natural nursing. The evidence of maternal ignorance abounded, but there do not appear to have been many clear signs of intentional neglect or actual unkindness. Dr. Dudfield pleads for the teaching of hygiene in our public schools, and advocates combined effort on the part of the sanitary authority and philanthropic agencies to secure the establishment of municipal *crèches*. He would also provide a municipal milk depôt for the supply of suitable food to the infants of the poor.

The Waste of Human Life.

The weekly return of deaths in London and in seventy-five other great towns, issued by the Registrar-General, furnishes food for much philosophical reflection. London, as a whole, shows the moderate mortality of 17·0 per 1,000 of population, which is estimated at 14,862,163 persons in the middle of the year. This ratio is slightly below that of England and Wales, namely, 17·4 per 1,000. An analysis of London districts reveals the usual striking difference in the mortality incidence, for instance, the ratio for Hornsey is 2·8; of Leyton, 8·6; of Tottenham, 9·2; and of West Ham, 15·5. The heavy death-rates, as usual, are met with in the poor and crowded districts, as St. George's-in-the-East, Whitechapel, and Southwark. Turning to the large towns, we find four with single figures, namely, Grimsby, which occupies the place of honour with a rate of 4·6, followed by Hastings with 6·3, Aston Manor with 8·6, and Reading with 9·2. The towns with the heaviest mortalities are those which have long earned an unenviable reputation as regards that test of wholesomeness in the past. The list is topped by Middlesbrough, with a death-rate of 25·1, and followed by Liverpool with 23·7, Tydvil 23·6, Preston 23·4, Salford 23·0, and Norwich and Smethwick each 22·0. These high averages point to an immense waste of human life, and the excessive returns from the foregoing towns form a standing reproach to the sanitary administration of the United Kingdom. The rate for Edinburgh is 15·8, of Glasgow 19·4, while that of Belfast is 22·4, and of Dublin 26·8, a comparison that may well set Irishmen thinking.

Week-end Recreations.

The busy times in which modern man is called upon to pass his existence leave their mark in the shape of a vast mass of nervous troubles and premature old age. The mischief of the thing lies chiefly in the continuity of the strain, on the principle of the bow which is ruined by being never unstrung. Indeed, with fairly regular intervals of rest and relaxation, it is almost incredible what an amount of exacting work can be got through by a man of affairs. The recognition of the necessity of change is shown by the popularity which has been accorded to the week-end holiday. Nowadays the coming of Saturday gives the signal for an exodus of politicians, journalists, business men, and jaded citizens of all degrees from town to country for a spell of fresh air if not always of sunshine. The braced-up energies of the man returning to the scene of his labours is a thing wonderful to see, and as a phenomenon has never been satisfactorily explained by medical science. Perhaps the class least able to benefit by the modern rage for week-end change is that of medical men, whose duties, as a rule, render absence from home difficult or impossible. There is more to be said in favour of this latter-day fashion than of most of the follies and crazes that fall under the mysterious laws whereby the actions of the multitude are guided, governed and controlled.

Venereal Disease and Sickness and Life Insurance.

It is generally held that an attack of syphilis radically depreciates the "life value" of the victim, and from a sickness point of view it may fairly be assumed that for some years after an attack the liability to disabling sickness is tangibly enhanced. The view is equally accepted that an attack of gonorrhœa entails no serious consequences once it has been recovered from, and it is not even customary to ask candidates for sickness or life insurance whether or not they have ever suffered therefrom. If, however, any practitioner asks himself which disease in his experience has most manifestly contributed to cause invalidity and premature death he will not improbably be disposed to state that the ultimate results of gonorrhœa are at least as disastrous as those of syphilis. For one case of locomotor ataxy or other nervous disease recognised to be dependent on syphilis there are probably many of enlarged prostate, vesical and renal disease directly due to the presence of an urethral stricture or to past irritation of the prostate. Then, too, there is such a thing as gonorrhœal rheumatism, which is far more frequent than is suspected in spite of the maxim that inflammation of a single large joint, apart from trauma, is generally of gonorrhœal origin. There is, of course, the fundamental difference that while in gonorrhœa any subsequent mischief is the direct consequence of a lesion ascertainable on examination, that associated with syphilis is more occult, and may give no indication of its existence until the symptoms of the impending disease present themselves. The question is one of considerable interest from the insurance examiners' point of view, and it can only be cleared up by the careful study of statistics which are of their nature very difficult to collect.

The Eyesight of London School Board Children.

The result of the systematic investigation of the eyesight of children attending the London Board Schools, carried on since February, 1902, by eight ophthalmic surgeons, goes to show that among the boys 8 per cent. and among the girls 11 per cent. suffer from more or less serious defects of the visual organs. It is noteworthy that the proportion of scholars with visual defects was much more marked in the poorer districts than in districts of a better class, and it is greatly influenced for the worse by the presence of children of foreign parentage. It is estimated that five years will be required to complete the examination of all the children, who number about 70,000. This result amply justifies the necessity for systematic examination of new scholars, since much of the labour bestowed on the defective children is thrown away in consequence of their physical inability to derive the benefit thereof.

How to Procure Sleep Without Narcotics.

In many instances of difficulty in getting to sleep and of positive sleeplessness, much may be done to afford relief without having recourse to insidious hypnotics. Going to bed too soon or too long after the last meal is a fertile source of sleeplessness and disturbed sleep. Those who partake of a substantial meal in the evening ought to allow an interval of from three to four hours before retiring to rest. An empty stomach is equally inimical to readily-induced, sound sleep, consequently those who retire late are more likely to enjoy a well-earned repose if they take a glass of milk, a biscuit, or other light food on going to bed. The latter class of sufferers may often be got to sleep merely by the administration of a carminative, of which the old-fashioned peppermint is the prototype. The practitioner ought, in justice to his patient, always to seek to restore the function by simple, non-injurious means, before prescribing hypnotics, which can at best afford but ephemeral relief, and the use of which is always attended by a tangible risk of the formation of a habit. The suggestion to give peppermint water with spirits of chloroform, or some similar combination, is one well worthy of a trial.

A New Preventive of Sea-sickness.

It is stated that fixing the eyes upon a mirror when the first symptoms of sea-nausea make themselves felt affords marked relief, the explanation being that the eyes and mirror form one body, so that the changing of horizons being reflected on a surface equal in every plane the eye loses consciousness of the different changes. We only hope it is true, but we are constrained to ask why simply closing the eyes should not have a similar effect? We know by sad experience that such is not the case, but that will not prevent our gazing into a mirror the next time we are attacked across the Channel as soon as symptoms of marine colic become obtrusive. A close analogy exists between sea-sickness and ordinary vertigo in that the immediate determining cause of the disturbance is, we are told, the "consciousness of the oscillation of the centre of orientation." On the other hand, there does not appear to be any necessary relationship between a proneness to vertigo when placed on a height and a special proclivity to sea-sickness. Moreover, the treatment would only be practicable on short trips and one cannot contemplate with equanimity a passage across the Atlantic spent either in the horizontal position with closed eyes or in the erect position with the eyes obstinately fixed on a mirror.

The Failing Eyesight Bogey.

When will ophthalmological experts cease to create needless alarm by asserting that our eyesight is failing merely because, as years go by, the proportion of persons wearing glasses steadily increases? It is surely obvious that this affords not the slightest indication of the quality of the national sight! We are familiar with the fact that unlettered people and children may present notable errors of refraction without being in any way inconvenienced thereby until the time arrives when they begin to use their eyes for close work, such as reading. Inability to focus objects within a given distance directs attention to a pre-existing defect, a condition of the eye, in fact, which only makes itself felt as a defect when an attempt is made to employ that organ for purposes for which it is unsuited. The prevalence of spectacles merely indicates the prevalence of occupations requiring for their proper fulfilment a degree of accommodation fully up to the average. Moreover, in the vast majority of instances vision is rendered perfectly normal by the use of glasses, so that the defect, such as it is, merely bears on one of the collateral and non-essential factors of actual vision.

Infanticide.

An interesting discussion has been going on for some time in Paris regarding the subject of infanticide in the animal world. Much evidence has been forthcoming to show that many animals undertake the destruction of those feeble or maimed or incapacitated from taking an active part in the struggle for existence. The two great governing instincts are those of self-preservation and procreation of healthy offspring. It would seem that when the offspring proves morbid or incapable of playing an effective part in life's struggle, the parental instincts were overborne and infanticide was practised. At this apparent cruelty in the animal world some would claim that we have evidence neither of caprice nor grudge but of an instinctive altruism. To students of mankind and those interested in the working of evolution, the subject is of much interest, and awakens many problems concerning the loss or lack of maternal instincts noticeable in not a few sensual women, and oftentimes leading to the neglect of infants or even actual infanticide.

The Mania of Depilation.

THERE is at present in the Salpêtrière Hospital at Paris a hysterical woman afflicted with a mania which prompts her to pick out her hair. For years she was subjected to vigorous treatment for supposed alopecia areata, and only close observation revealed the fact that the bald spots owed their presence to the patient's own perverseness. A curious point in the history of this patient is that from the age of seven she displayed an uncontrollable tendency to pick things to pieces. When this destructive inclination was checked by physical means she had attacks of dyspnœa and precordial distress, which she sought to relieve by pulling her fingers or ears, inflicting upon herself various painful lesions.

The Conference on Tuberculosis.

THE Conference on Tuberculosis which took place last week at Berlin attained the object in view, which is to bring together for purposes of discussion and mutual enlightenment physicians from various parts of the world who are specially engaged in the study of tuberculosis. The interest of the meeting, however, centred on the elaborate discussion of the views regarding the non-interchangeability of bovine and human tuberculosis, first promulgated by Professor Koch, in London, at the Congress of Hygiene. No fresh light seems to have been thrown on these vexed questions in the course of the discussion, although Dr. Heron is reported to have stated that in spite of the partial abandonment of the precautions hitherto taken against the consumption of meat, &c., of tuberculous cattle there had been no increase in the British death-rate from the disease. Dr. Koch's main argument appears to be based on the fact of the extreme rarity of primary tuberculous lesions of the alimentary tract and the absence of widespread epidemics due to the consumption of tuberculous milk and meat. He holds that the expenditure which would be entailed by the attempt to stamp out the disease among cattle, would be more profitably employed in improving the dwellings of the poor and in providing sanatoria. We shall, however, be in a better position to discuss the matter when the full reports are before us.

Clerical Longevity.

IT appears from a report recently issued by Mr. Archibald Hewat, F.I.A., in which is embodied fifty-five years' experience of the widows' and orphans' fund of Scottish Presbyterian ministers, that they and their wives greatly outlive the ordinary "healthy males" of the insurance tables. The prolongation of life on the part of the ministers reduces the claims on the widows' and orphans' funds by over 5 per cent.; but, on the other hand, when the widows do get a claim, they fare nearly 3 per cent. better than even female Government annuitants, which is saying a good deal. These figures go to prove what no one has ever disputed, that regular and temperate habits promote longevity.

The Medical Defence Union.

IT is announced that on and after January 1st, 1903, all new members will be required to pay an entrance fee of ten shillings, but the annual subscription will not be increased, remaining as heretofore, ten shillings.

THE annual general meeting of the Royal Academy of Medicine in Ireland will be held at the College of Physicians, Kildare Street, on Friday next, the 31st inst., at 4.30 p.m.

PERSONAL.

LIEUTENANT-COLONEL A. M. DAVIES, R.A.M.C., has been temporarily appointed a member of the Medical Advisory Board.

DR. J. WARD COUSINS has been appointed to represent the Royal College of Surgeons of England on the Central Midwives Board.

FIELD-MARSHAL EARL ROBERTS, K.G., will distribute the prizes at St. George's Hospital Medical School to-morrow (Thursday), the 30th inst.

MR. W. H. POWER has been admitted a Fellow of the Royal College of Surgeons of England under the regulation relating to members of twenty years' standing.

DR. J. KINGSTON FOWLER will deliver the opening lecture of the winter session at the Hospital for Consumption and Diseases of the Chest, Brompton, to-day (Wednesday) at 3 p.m.

DR. W. G. SMITH, physician to Sir P. Dun's Hospital, has been re-elected to the post of King's Professor of Materia Medica and Pharmacy in the School of Physic, Trinity College, Dublin.

MR. JOHN WEBSTER BRIDE, formerly of Epsom College, and now of the Owens College, Manchester, has been elected by the Royal College of Surgeons of England tenth Jenks Scholar.

AT the annual dinner of the York Medical Society, Dr. Edmund M. Smith, Medical Officer of Health for York, was presented with a handsome silver rose-bowl in recognition of his services to the Society as hon. secretary for six years.

WE regret to learn that Sir Lauder Brunton has been suffering from blood-poisoning, and it is with corresponding satisfaction that we are informed that he is slowly recovering therefrom, and will, it is hoped, be enabled to resume practice after a period of rest and change.

We regret to learn that Mr. Lennox Browne, F.R.C.S.E., is lying dangerously ill, and that recovery is almost hopeless.

Mr. David Caldwell McVail, M.B., has been nominated for a further period of five years from October 28th, 1902, a member of the General Medical Council, for Scotland.

Dr. James Little has been nominated for a further period of five years from November 26th, 1902, a member of the General Council of Medical Education and Registration of the United Kingdom, for Ireland.

At the Investiture held by his Majesty on Friday last the following members of the profession were presented and "invested":—

K.C.B.—

Surgeon-General J. A. Woolfryes, M.D., Hon. Physician to the King.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

SCOTLAND.

[FROM OUR OWN CORRESPONDENT.]

Notification of Pulmonary Tuberculosis.—A circular has been issued to the medical profession in Edinburgh by Sir Henry Littlejohn, acting under the instruction of the Health Committee, requesting their co-operation in obtaining, by a voluntary system of notification, precise information as to the amount of phthisis in the city. For each notification a fee of half-a-crown will be paid, and the information obtained will be regarded as strictly confidential. In no case will there be any official interference with patients either at home or in connection with their occupations, the steps taken being confined to sanitary inspection and disinfection where desired.

St. Andrew's University.—Mr. Andrew Carnegie, who was a year ago unanimously elected Lord Rector of St. Andrews, was formally installed in office on October 22nd. Advantage was taken of the occasion to confer the honorary degree of Doctor of Laws on the members of the Carnegie Trust, and on the United States Ambassadors to England, Germany, and Italy, and on Mr. Graham Bell, the inventor of the telephone. The Vice-Chancellor having opened the proceedings with prayer, Mr. A. G. Abbie, chairman of the Students' Representative Council, announced that Mr. Carnegie was unanimously elected Lord Rector last October, and asked the Vice-Chancellor to instal him in office. After being robed, the Lord Rector delivered his address, taking as his subject, "The Industrial Supremacy of the World."

Glasgow.—The result of the polling in the Rectorial Election was announced on Saturday afternoon, when it was found that Mr. George Wyndham had a majority of twenty-nine votes over Mr. John Morley. Mr. Wyndham had a majority in two nations—Glottiana (Glasgow and Lanarkshire) and Londoniana (Ayr and Renfrew), Mr. Morley in one—Transforthiana, while in Rothseiana (Bute and Western Highlands), the candidates tied with 112 votes each.

Glasgow District Asylum.—The annual report of this institution states that the population of the asylum is increasing rapidly, and that the increased accommodation in course of construction is urgently needed. The existing buildings provide for 850 beds; but on May 15th, 1902, there were 856 adults chargeable, an increase of thirty over the previous year. There were also twenty-five juvenile imbeciles in the detached villa erected for such cases, an increase of four. The discharges numbered 193, and the deaths seventy-six, or 8·8 per cent., as against 9·4 last year; while the recovery rate was 38·28 per cent., as against 29 per cent. in 1900-1. Keeping in view the present-day treatment of phthisical patients, the Board was about to erect at Woodilee and Gartloch asylums sanatoria for such cases. That at Woodilee will provide sixty-two beds. These erections are to be built of iron and wood, which, both as regards economy and speed in construction, are held to present advantages over brick and stone. They will be the first of their kind in Scotland connected with asylum administration. Plans have been approved of a home to accommodate 110 nurses, as well as of a pathological laboratory, which it is hoped will meet the growing necessities for scientific investigation.

Edinburgh University Rectorial Election.—The candidates were formally nominated on October 22nd, when it was intimated that the poll would take place on November 1st.

BELFAST.

[FROM OUR OWN CORRESPONDENT.]

Royal Victoria Hospital.—The winter session at the Royal Victoria Hospital was opened on Tuesday, October 20th, with an address by Dr. W. B. McQuitty, Assistant Physician, a full abstract of which will be found in another column. There was a large attendance of the medical staff and students. If no hitch occurs the next opening address will be delivered in the new hospital, which is now nearly ready for occupation. The number of students entered for the session cannot be told for a week or two yet, as there are always some late arrivals.

Mater Infirmorum Hospital.—I deeply regret to have to record the death of one of the most brilliant members of the staff of the Mater Infirmorum Hospital — Dr. Daniel McDonnell. Dr. McDonnell had been suffering from pulmonary disease for the last few years, and succumbed to it on

October 10th. He received his medical training at the Catholic University School of Medicine in Dublin, and, after a distinguished career in the Royal University of Ireland, he graduated in 1885. In addition to being physician to the Mater Infirmorum Hospital, he held the post of medical officer to the Royal Irish Constabulary of the north district of Belfast. Dr. MacDonnell's literary powers were considerable, and his criticisms and papers on philosophical and metaphysical subjects attracted attention. Great sympathy is felt by his professional brethren for his sisters, who have lost several of their nearest relatives in a short space of time.

THE TRAFFIC IN OLD HORSES.

WITH reference to our remarks on this subject in a recent issue, we have been making further inquiries, and find that there is a legalised and recognised business in horseflesh as a regular article of diet among the Continental poor, as much as 5½d. per lb. being paid for prime cuts, and that all the horseflesh so exported is consumed in this way in the country to which it is sent, and never returns to England in any form.

THE PREVENTION OF QUACKERY.

To the Editor of "THE MEDICAL PRESS AND CIRCULAR."

SIR,—With reference to the excellent leader on the above subject in your last issue, I would point out that it seems out of the question to expect Parliament to legislate for protecting any interest of a profession not also necessary for the protection of the public. The medical profession must not, therefore, expect that any law will ever be proposed having as an object to prevent practice by unqualified quacks unless it can be shown that such practice is widely injurious to the public welfare. Surely to prove this must be quite easy. Evidence can be found in overwhelming quantity in every hospital throughout the country. Scores of patients can be produced weekly or daily illustrating both the cynical cruelty of the sham medical practitioner, and the harm – not less cruel and deliberate—inflicted by the concocter and vendor of fraudulent nostrums. That laws can be devised and enforced for the protection of the public against similar fraud is proved not only by the case of the legal profession which you instance but by the case of the veterinary surgeon. It is very much more difficult for unqualified quacks to practice upon animals than upon man, and falsely to assume any title implying qualification under the Veterinary Act leads at once to prosecution and conviction; whereas it is impossible to prevent medical quacks from adopting titles sufficient to lead the public to take them for legally qualified practitioners. No other profession in a similar position would rest as apathetic as ours. We are great in numbers, and in the honourable position of the bulk of our members. Why, then, do we not let our voices be heard? We have, in the British Medical Association an organisation through which our voice might be made audible; and whenever the present question is broached I ask myself why the Association does not take it up and see it through. It appears to me that the Association remains what it was described to be a few years ago, namely, a mere co-operative society for the publication of a cheap medical newspaper. For that reason I write now no longer as a member of the B.M.A., but rather as a reader and supporter of THE MEDICAL PRESS.

I am, Sir, yours truly,
AN OBSCURE PRACTITIONER.
October 23rd, 1902.

ARSENICATED TOBACCO.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I note in your issue of the 15th inst. that in the article on p. 414 entitled "Arsenicated Tobacco," the writer says, "We fear our worthy analysts have not been in the habit of testing tobacco for this deleterious agent," but I beg to state that some years ago my colleague, Dr. William Murrell, and myself, took much trouble in this matter, and published a communication on the subject in a medical contemporary, in which we drew special attention to the presence of arsenic in tobacco wrappers. We examined seventeen samples of tobacco and cigarettes, and in six of these arsenic was present in quantity in the wrappers, and notably in some well-known brands, the wrappers of which were green in colour, although it is only fair to say that not all green wrappers were thus contaminated. In the various tobaccos no arsenic was present, but that the use of such wrappers must not only be seriously harmful to the work people employed but conducive to poisonous contamination of the tobacco itself is an obvious deduction.

I feel, however, that the public is very apathetic where its palate is concerned, and will continue to smoke its favourite brands as heretofore, undeterred by the "scares" of analytical chemists or medical men; but your recent able article on the subject will doubtless have a beneficial effect in once more calling the attention of the medical profession to the possibility of arsenic in tobacco "forming an important factor in the production of various morbid conditions."

I am, Sir, yours truly,
H. WILSON HAKE, Ph.D.,
Lecturer on Chemistry and Toxicology at the Westminster Hospital Medical School.
Chem. Lab., Westminster Hosp. Med. Sch.,
Oct. 21st, 1902.

Literature.

MANUAL OF SURGICAL TREATMENT. (a)

PART V. of Messrs. Cheyne and Burghard's work on surgical treatment has now been some time in print. It deals with the surgical affections of the head, face, jaws, lips, larynx and trachea. The latter chapters deal with the intrinsic diseases of the nose, ear and larynx, and are under the authorship of Mr. H. Lambert Lack.

From a careful perusal of this volume we do not hesitate to say that it in no way falls below the standard of its predecessors. We consider those sections especially worthy of commendation which deal with intracranial suppuration, focal epilepsy, tumours of the brain, malignant disease of the upper jaw, cleft palate, operations upon the larynx and trachea. The advice given as to the course of treatment to be followed in this extensive field of surgery should go a long way to enhance the reputation of the work and its authors, as it bears the stamp of wide experience coupled with sound judgment. The surgical procedures recommended are thoroughly up to date, and the rules for the guidance of the practitioner are concise and explicit. In the latter sections of this volume, viz., those concerned with the intrinsic diseases of the nose, ear, and larynx, Mr. Lambert Lack has succeeded in performing his task in a highly creditable manner. We cannot but allude in the highest terms to his contribution on the treatment of the inflammatory affections of the accessory cavities of the nose; this part is exceedingly well done. The chapters dealing with suppurative inflammation of the middle ear, antrum, and mastoid cells are also excellent, and add much to the usefulness of this volume.

Part VI., Section I.—In the preface the authors state that it had been their intention originally to complete the series in six volumes, but in order not to condense the subject-matter too much, and to avoid a volume of bulky proportions, they decided to divide the last part into two volumes, and in this they have undoubtedly exercised a wise discretion. This volume deals with the treatment of the surgical affections of the tongue and floor of the mouth, the pharynx, neck, œsophagus, stomach, and intestines. One of the most important chapters is that which is devoted to the treatment of malignant disease of the tongue. It is headed "Cancer of the Tongue: Sarcoma and Epithelioma." We think this title is open to misapprehension, as it would lead one to the conclusion that the authors include both sarcoma and epithelioma under the heading "Cancer of the Tongue." We consider it preferable to reserve the term cancer for the *epithelial* form of growth, and that it should be clearly differentiated from the sarcomatous or *connective tissue* variety of malignant disease. The treatment of cancer of the tongue, however, is well handled, and will amply repay perusal. The section dealing with tuberculosis of the cervical glands is another which stands out prominently, and has received very careful attention on the part of the authors: the advice given as to treatment is thoroughly sound, and it is to be regretted that it is not more widely followed. The chapter on the surgical affections of the thyroid gland is good, especially that part devoted to thyroidectomy, Those devoted to ulceration and cancer of the stomach leave nothing to be desired; they are, indeed, to our mind perhaps the best in the volume. A praiseworthy feature to be noted here is the improved style of the illustrations. We are convinced that the poorness of the illustrations in the earlier volumes detract very considerably from the attractiveness of the work. At the same time we cannot refrain from expressing our contempt for a class of medical literature which has been foisted upon the profession of recent years, its principal characteristic being attractive-looking illustrations, flash binding, but—to put it mildly—a most disappointing letterpress. In the present instance, however, we have no such fault to find, but we think the authors would be well advised in maintaining the standard of the illustrations at the same pitch of excellence as the text. Of the remaining chapters of this volume those concerned with appendicitis and hernia are most deserving of note. We agree in the main with the methods of operation recommended, and consider that both subjects have been dealt with in a truly comprehensive manner. This volume is, perhaps, the most valuable of the series to the general surgeon, as it deals with a class of ailments which is constantly coming under his notice. We unhesitatingly recommend this work no less to the specialist than to the general practitioner, as being thoroughly trustworthy, well up to date, and the best of its kind in the English language. We congratulate the authors upon the result of their labours, and we look forward with pleasure to the concluding section of the work.

(a) "A Manual of Surgical Treatment." By W. Watson Cheyne, C.B., M.B., F.R.C.S., F.R.S., Professor of Surgery in King's College, London, and F. F. Burghard, M.D. and M.S.Lond., F.R.C.S., Teacher of Practical Surgery in King's College. Parts V. and VI. (Section I.). London: Longmans, Green and Co. 1902.

WILLIAMS ON THE RONTGEN RAYS. (*a*)

This book is written by a well-known American authority on the medical application of the Röntgen rays. It forms a valuable treatise on the subject, and embodies the results of a great amount of practical work. Dr. Williams is perhaps best known to English readers by his researches in the application of the Röntgen methods to physical diagnosis. The section of his book dealing with that particular part of his subject is carried out exhaustively, and forms the best description of the kind with which we are acquainted. The methods of examination are fully illustrated and described, together with diagrams, radiograms, and charts of pneumonia, hydrothorax, pneumothorax, tuberculosis, aneurysm, and various other morbid conditions of the heart and lungs. A feature of the book is the large number of illustrations, which are, for the most part, excellent. Some of the radiograms, indeed, are among the best we have seen, and represent the most advanced stage of Röntgen photography. Fig. 318 shows acute periostitis of the radius in a striking manner, and has many soft-tissue shadows. The section on apparatus is very full, and indicates a variety of appliances that will hardly find favour among operators on this side of the Atlantic, whose apparatus is usually of the simplest kind. Dr. Williams hardly gives the prominence to stereoscopic methods which we imagine it deserves, nor does he give quite enough credit to English observers. Thus, in the localisation of foreign bodies in the eye we see no mention of Mackenzie Davidson's special work, which is certainly of a brilliant kind. Davidson's localiser is alluded to elsewhere in the book. Nor do we find any reference to Dr. Walsh's book on the Röntgen rays in medical work, although it was the first systematic treatise written on the subject, and contains a wealth of reference matter which can hardly have escaped the author's attention. With these brief criticisms we leave this excellent book, and shall look forward with interest to future editions.

DORLAND'S MEDICAL DICTIONARY. (*a*)

The present age of encyclopædias and dictionaries has not been unfruitful in the fields of medicine. Dr. Dorland, of Pennsylvania, has made the latest addition to the list of dictionaries in the shape of an illustrated medical work dealing with the terms used in medicine, surgery, dentistry, pharmacy, chemistry and the kindred branches. The field is therefore a wide one, especially as the author has included tables of muscles, nerves and other anatomical systems, together with eponymic signs, tests and a great variety of miscellaneous information. So far as we have been able to test the matter, the information is accurate and useful. Turning to "Plasmodium," we find the malarial form described in some fourteen or fifteen lines, while on the opposite page is an excellent coloured plate of the various forms and stages of the malarial parasites. We find no mention, however, of the "high-frequency" current, which is being used so largely in cancerous and other affections, although it appears under the less well-known title of the D'Arsonval current. Nor, under "Treatment" do we find any mention of the Tallerman superheated air treatment, which in many arthritic affections is one of the most valuable methods introduced into modern medicine. The only mention of anything of the kind is under "Hot-air Bath," of which the temperature is stated to be 100° or 130°F. It is well known that the good effects of the Tallerman method are obtained at higher temperatures. Among other useful features of this book may be mentioned a table of elements and a long list of bacteria. Some of the coloured illustrations are exceedingly good, as, for instance, that of tubercle bacilli in sections of tissue and in sputum. The author, on the whole, has succeeded in producing a complete and handy dictionary, in moderate compass, which, although it cannot compete with Gould's incomparable medical dictionary, yet any medical man who purchases it will find it a valuable book of reference and will be able to refresh his memory on many points arising from practice.

TRAITE DE MEDECINE ET THERAPEUTIQUE. (*b*)

This, the penultimate volume of the series, deals exclusively with diseases of the nervous system—of the cerebrum, the pons, the meninges, and of the spinal cord and its membranes. The fact that the chapters are contributed by authorities of such world-wide fame as Bourneville, Raymond, Claude. Hutinel, Klippel, Dejerine, Thomas, Gilbert, and Lion is a sufficient guarantee that the text is worthy of the subject. The subject is a wide one, but is adequately handled in close upon a thousand closely-printed pages.

Disease of the nervous system is a branch of medicine in which very marked progress has been accomplished during the last two or three decades—progress which has been rendered possible by combined pathological investigation and clinical observation. It is

---

(*a*) "The Röntgen Rays in Medicine and Surgery." By Francis H. Williams, M.D., Visiting Physician, Boston City Hospital, &c. London and New York: Macmillan Company. 1901. Price 24s.

(*a*) "Illustrated Medical Dictionary." By W. A. N. Dorland, A.M., M.D., Assistant Obstetrician, University of Pennsylvania, &c. W. B. Saunders and Co., Philadelphia and London.

(*b*) "Traité de Médecine et Thérapeutique." Publié sous la direction de MM. P. Brouardel et A. Gilbert. Vol. IX. Paris: J. B. Bailliere et Fils. 1902.

worthy of note that such progress is due in no small measure to the labours of British observers whose names figure large in the impartial and comprehensive *historiques* of the various morbid conditions.

Beginning with the study of general inflammatory states of the cerebrum, respecting which there is nothing much that is new to be said, we pass on to diseases of special parts of the central nervous system. It is in this department that the most substantial advances have been achieved, and the reasoning whereby symptoms are referred to strictly localised lesions is calculated to excite admiration. It is unfortunate that the deductions so ingeniously suggested are only possible to the comparatively few whose knowledge of the anatomy of the nervous system has been sedulously cultivated. In no department of medicine is accuracy of anatomical knowledge so essential to an approximately correct conclusion as in the recognition of specific lesions of this or that segment of the cerebro-spinal axis. In a general way the practitioner can fortify himself by looking up the subject and thus arrive at a reasoned diagnosis, but in diseases of the nervous system he is still at a loss, because the explanations are useless in the absence of a well-grounded familiarity with the anatomical arrangement of the parts under consideration, a long and arduous study in itself.

We cannot but praise the precision and the lucidity of the text. The style is really inimitable, and constitutes one of the attributes of the *génie francais*. Such a work as this defies analysis, and is beyond detailed criticism. There is an absence of that literary offhandedness which consists in offering to the reader a *pot pourri* of other people's hypotheses. Each contributor handles his subject from his own point of view, and one feels that he has mastered his subject and has thought out the problems for himself instead of leaving his reader to winnow the wheat from the chaff. If the therapeutical information lays behind the clinical and pathological the fault is inherent to the subject, and cannot be debited against the authors. It is a regrettable fact that diseases of the nervous system for the most part are refractory to therapeusis, with the exception of those in which there is reason to suspect a specific origin. Nevertheless the all-important subject of treatment is as fully dealt with as circumstances permit, and we are at any rate placed in possession of such remedial measures as are suggested by the indications.

The next and final volume is announced to appear very shortly, and its publication will complete a System of Medicine which it will be difficult to surpass for comprehensiveness and wealth of information.

WEST ON THE RESPIRATORY ORGANS. (*a*)

In the preface to this important work Dr. West says:—"If I had known beforehand the time and labour this book would have cost me, . . . I much doubt whether I should have had courage to undertake it." We rejoice that he did not know, and that his ignorance in this respect has permitted him to give us such a splendid addition to medical literature.

The plan of the book is excellent, "the relative importance of its parts being indicated by types of different kinds" with well-marked headings in heavy type, which make it clear and easy to find out sections which may be specially sought for. This clearness is carried into the text, which is written with crispness, simplicity, and an absence of padding, that make its study easy and pleasurable. Here is an example taken at random from the section on "Pulmonary Infarct":—"When the lungs are removed from the body the parts around retract, so that the infarct stands out somewhat prominently above the surface. The parts affected are dark purple or nearly black in colour, but they become red on section and exposure to the air. They are sharply defined from the surrounding lung, are firm, airless, and sink in water."

The above also serves as an example of the manner in which the morbid appearances are dealt with, the pathology of each subject being similarly clearly and fully discussed. "Clinical cases are all printed in small type," and are models of what such forms of illustration should be, the whole being in a nutshell, without any of the wearying details and useless minutiæ which usually accompany such, and cause us, as a rule, to pass them carefully over. Here they are inserted throughout the text to illustrate interesting or unusual features which are there referred to, and seldom occupy more than six lines of print.

The rest of the small type is well selected and of great interest, for it does not follow that because it is in small type it is of little importance, and a glance will show the practitioner that here he will find most that will specially interest him and tempt him to further reading.

Dr. West discusses the treatment of the various disorders and their symptoms exhaustively and with dignity; the book is not soiled with strings of new-fangled remedies of which we know little or nothing, exploited, for the most part, by enterprising chemists and druggists, and the employment of which is little short of quackery.

The book is well illustrated with charts and a large number of diagrams and pictures—the number is not stated, as they are not used for the purpose of padding, but are all highly useful and instructive. A large proportion of these are original, others are from well-recognised and trustworthy sources. There is nothing elaborate about them; they are plain, well done, and illustrate what they are intended to represent. The two volumes are of a handy size, well bound, with light good paper, clear printing, well proofed, and with an excellent index.

We congratulate the author on the production of these volumes.

EPILEPTIC COLONIES. (*a*)

This valuable report is the outcome of the far-seeing policy of the Committee of the proposed colony for epileptics which is shortly to be inaugurated at Warford, near Alderley Edge, in Cheshire, in sending Dr. Rhodes and Mr. Marshall to gather ideas in America. We are now accustomed to gather suggestions from our trans-Atlantic cousins, and certainly this volume clearly shows that in the formation of colonies and hospitals for the epileptic we have much to learn from the United States. In the short space of four weeks Dr. Rhodes and his companion visited nearly twenty hospitals and colonies, and this report is a remarkable record of concentrated energy worthy of Brother Jonathan himself. The plans and numerous illustrations, as well as the very clear accounts, give an admirable idea of American methods, and all interested in the establishment of institutions for the epileptic or mentally afflicted classes or concerned in their control and conduct would do well to study this excellent report.

THE HEALTH OF FINSBURY. (*b*)

The reports of medical officers of health should arouse more than a mere local interest. Not only are they valuable records of work done in certain districts, but they afford material for comparative study, and furnish suggestions which might be of more or less general applicability. Dr. Newman's report, the first annual record of the public health and sanitary condition of the Borough of Finsbury as constituted under the London Local Government Act, 1899, is in every way excellent. It is conveniently divided into sections dealing with vital statistics, records of disease, protection of food supply, house property and overcrowding, and general sanitary administration.

The pages devoted to a consideration of the recent outbreak of small-pox are a peculiarly interesting part of

(*a*) "Report on a Visit of Inspection to Colonies and Hospitals for Epileptics, the Feeble-Minded, and the Insane, in the United States of America." By J. Milson Rhodes, M.D., and Edwin W. Marshall, C.A. Pp. 51, with Illustrations and Plans. London: P. S. King and Son. 1902

(*b*) "Report on the Public Health of Finsbury. 1901." By George Newman, M.D., F.R.S.E., D.P.H., Medical Officer of Health of the Metropolitan Borough of Finsbury. Pp. 180. With Tables and Charts. London: Thomas Bean and Son. 1902.

the volume. The control of phthisis receives much consideration. We are glad to see that voluntary notification is affording valuable results.

We hope Dr. Newman, in his next report, may be able to furnish a map of his district. Every report of this kind must be reckoned incomplete without a satisfactory delineation of the district under consideration.

Obituary.

ADOLPH RASCH, M.D.

The death occurred, on the 17th inst., at Halle an der Saale, of Dr. Adolph Rasch, who was well known in London, having practised here a number of years as a physician. For many years he was chief physician of the German Hospital in Dalston. He was also for four years president of the German Athenæum. A stroke of paralysis, from which he afterwards recovered, rendered it necessary for him to relinquish his practice as a physician. He then retired with his family to Germany, and spent the rest of his days at Halle an der Saale. As a physician he was a man of great eminence, and at the same time a great friend of the poor. Dr. Rasch leaves a widow and three daughters.

Medical News.

Boracic Acid in Shrimps.

A Southport fisherman was proceeded against at Wigan last week, for selling shrimps which contained forty grains to the pound of boracic acid. The evidence of the medical officer of health was to the effect that the presence of the acid *might* prove injurious to the health of the consumer, but the magistrates held that the prosecution had not made out their case, which they therefore dismissed.

A Medical Impostor.

A curious story of imposture by a man who pretended to be a qualified practitioner was unveiled at Carmarthenshire Quarter Sessions last week. The accused was a young man, described as a mason, who was charged with having obtained various sums of money by pretending that he was Dr. Davies, of Ammanford. Owing to a technical defect in the evidence the prisoner was discharged, but he was forthwith arrested by a Swansea police officer presumably in order that he may be charged with other offences.

Deaths Under Chloroform.

A girl, æt. 14, died under chloroform at St. Thomas's Hospital last week when about to undergo an operation on an injured eye. The usual verdict was returned. A similar fatality is reported from Leeds, where a woman, æt. 49, died after thirty-five minutes' chloroform anæesthesia. In neither case are any details forthcoming as to the method of inducing anæsthesia or the amount administered. A third death under chloroform took place at Guy's Hospital, the victim being a school teacher, æt. 44, who was suffering from cancer of the tongue. Death did not take place until twenty-five minutes after the cessation of the administration and five minutes after the completion of the operation, so that the chloroform may not have been the immediate cause of death. The anæsthetic was administered by the assistant house surgeon, who stated that only about 90 minims (!) of the drug had been given. A verdict of death from syncope was returned at the inquest. A fourth death occurred, in private practice, in Holloway, where a woman, æt. 34, succumbed to chloroform administered for the purpose of an abdominal operation.

An American Medical Mendicant.

A man called Clarence Perry, æt. 46, described as an American doctor, was charged at the Marylebone Police Court last week with obtaining money under false pretences from Dr. De Watteville. He had already been charged with similar offences, but as the evidence of false pretences was rather flimsy the magistrate discharged him with the advice that he had better not come before the Court again.

Hospital Officers' Association.

At the inaugural dinner of the newly-formed Hospital Officers' Association Mr. Lewis Glenton Kerr, of the Great Northern Central Hospital, presided, in the unavoidable absence of Mr. Adrian Hope, and a most enjoyable evening was spent. The chairman briefly explained the objects of the association, which are, among others, to promote social intercourse between the various branches of the hospital services; to disseminate practical information and progressive ideas concerning hospital work, and to arouse a keener interest in the advancement and prosperity of the medical charities of this country.

Dublin Death Rate.

The deaths registered in the Dublin registration area during the week ending Saturday, October 18th, 1902, represent an annual rate of 27·5 in every 1,000 of the population. Tuberculous disease caused 26 deaths; diseases of the circulatory system, 20 deaths; diseases of the respiratory system, 42 deaths; diseases of the nervous system, 17 deaths. One hundred infants died during the week, of whom 56 were under one year old. Within the city proper the death rates of the following districts were: South Earl Street 24 in every 1,000: Lisburn Street, 40·8 in every 1,000; and in Castle Street, 57·9 in every 1,000.

A Huxley Memorial.

The name of Professor Huxley will always occupy a prominent position among the pioneers who have struggled to secure a proper place for scientific study in our British methods of education. He stands out as one of the comparatively few medical men who have broken through professional limitations and taken a part in the formation of public opinion on many scientific points of vital importance. It is well, therefore, that we should be reminded of the debt we owe to Huxley. Professor Welch, at Charing Cross Medical School, in giving the recent Huxley lecture, has shown us how the influence of Huxley still lives on as an active force. It is pleasing now to note that Ealing has placed a memorial tablet in the public library as a birthplace memorial to the great scientist. The tablet bears the following inscription:—"The Right Hon. Thomas Henry Huxley. Born at Ealing, May 4th, 1825. Died at Eastbourne, June 25th, 1895. Try to learn something about everything, and everything about something."

The Cancer Research Fund.

A donation of £100 has been made by a lady, through Mr. A. W. Mayo Robson, F.R.C.S., to the Cancer Research Fund of the Royal College of Physicians of London and the Royal College of Surgeons of England, and of which the Prince of Wales is president.

Pass Lists.

Society of Apothecaries of London.

The following candidates passed in October:—

Surgery: R. Appleton (Sections I. and II.), F. M. Boclet (Section II.), J. B. Bradley (Sections I. and II.), K. A. Dawson (Sections I. and II.), I. Griffith (Section II.), P. S. Hopkins (Sections I. and II.), H. Johnson (Section II.), J. A. Jones (Sections I. and II.), C. E. H. Leggatt (Sections I. and II.), C. H. Osmond (Sections I. and II.).

Medicine: J. J. Anning, R. Appleton (Sections I. and II.), K. A. Dawson (Section II.), H. Johnson (Sections I. and II.), J. A. Jones (Sections I. and II.), J. P. Nettell (Sections I. and II.), F. W. B. Young (Sections I. and II.).

Forensic Medicine: J. J. Anning, H. Johnson, J. A. Jones, J. P. Nettell, F. W. B. Young.

Midwifery: R. Appleton, R. J O. Harley, J. A. Jones, W. Lovell, C. C. Rushton, J. H. K. Sykes, F. J. Turner, S. H. R. Welch.

The diploma of the Society was granted to the following candidates, entitling them to practice Medicine, Surgery, and Midwifery:—J. J. Anning, K. A. Dawson, P. S. Hopkins, J. A. Jones, H. Johnson, C. E. H. Leggatt, C. H. Osmond, and F. W. B. Young.

Notices to Correspondents, Short Letters, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Original Articles or Letters intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

DANGER IN INKSTANDS.

A German bacteriologist is reported to have discovered a micro-organism which inhabits mouldy ink and is fatal to rats and guinea-pigs. The harm done by ink, however, is much greater when it is used in the ordinary way, microbe or no microbe, for a few words traced therewith have been known (*vide* Shakespeare) to "undo a man." In many instances, indeed, less discomfort would have followed its infection than resulted from its use as a writing material.

Paterfamilias.—Our correspondent is referred to the introductory article in our "Educational Number" of September 17th, wherein he will see the pros and cons fully discussed.

Status.—We are not in possession of recent English statistics but in the United States it appears that 1 of every 400 railway employés is killed each year, and 1 in 26 injured. Among passengers the average mortality from injury is only 1 in 2,150,000 1 in 121,748 being injured. Calculated in another way, viz., by mileage it is stated that one may travel 3,500,000 miles without being injured, and 61,500,000 miles without being killed, so that railway travelling is, in reality, safer than being in bed.

Credo.—An "expert" is one who possesses exceptional skill or knowledge derived from personal experience. Mere erudition or book knowledge does not confer the status. In practice an expert is often one who knows something of the subject as compared with others who know nothing.

M. R. S.—Your figures do not correspond to those in our possession. The official returns of small-pox in the United States from June 23rd to Oct. 3rd, 1902, show 7 375 cases, with 388 deaths, as contrasted with 10,112 cases, with 291 deaths, during the corresponding period of 1901.

TREATMENT MADE EASY.

"Medsin chests!" said the old retired skipper, with a snort of contempt. "No such tomfoolery aboard my ship when I went to sea! Ketch me a coddling of my crew. No, sir, if any of the 'ands was feeling queer I jest asks him 'W'ere's the pain? Is it above or below the belt?' If 'e sez it's above the belt I gives 'im a hemmetic: if 'e sez it's below the belt I gives him a dose of Hepsom sorlts. That's what I calls 'curing 'im! Turn my ship into a chemist's shop! Not me, sir!"

Mr. H. H.—It is not customary to give the names of writers of editorial articles.

Meetings of the Societies, &c.

Wednesday, October 29th.

British Balneological and Climatological Society (20, Hanover Square, W.).—8.30 p.m. General Meeting. 9 p.m. Ordinary Meeting. Dr. E. Symes Thompson: Far Away Climates. (Presidential Address.)

Thursday, October 30th.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—5.30 p.m. Sir W. Broadbent on "The Pulse."

Tuesday, November 4th.

Medical Graduates' College and Polyclinic (22, Chenies Street W.C). —5.30 p.m. Mr. Hutchinson on "Inherited Syphilis."

Westminster Hospital (Broad Sanctuary, S.W.).—4.30 p.m Mr. Hartridge: Ophthalmological Cases. (Post-Graduate Clinical Demonstration.)

Thursday, November 6th.

Rontgen Society (20, Hanover Square, W.).—8.30 p.m. Opening Meeting.

Appointments.

Caie, William J., M.A., M.B., Ch.B.Aberd., Public Vaccinator for the Burgh of Bury St Edmunds.

Lindsey, Colin Dunrod, M.B.Lond., L.R.C.P.Lond., M.R.C.S., Medical Officer to the Plymouth Public Dispensary.

Littlewood, J. O., L.R.C.P.Lond., M.R.C.S., Certifying Surgeon under the Factory Act for the Mansfield District of the County of Nottingham.

Panting, Laurence C., M.A., M.D. B.Ch.Oxon., Honorary Medical Officer to the Royal Cornwall Infirmary, Truro.

Ratcliff-Gaylard, James, M.D.Brux., L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasg., Certifying Factory Surgeon for the Truro District of the County of Cornwall; Medical Officer of the Truro Workhouse and St. Clement's District; and Public Vaccinator of the St. Clement's and East Kenwyn Districts of the Truro Union.

Rigby, W.C., M.B., Ch.B.Vict., Certifying Surgeon under the Factory Act for the Adlington District of the County of Lancaster.

Soltau, Alfred Bertram, M.B.Lond., L.R.C.P.Lond., M.R.C.S., Medical Officer to the Plymouth Public Dispensary.

Traylen, C. L., M.R.C.S., L.R.C.P.Lond., House Surgeon to St. Mark's Hospital for Fistula.

Ward, James Philip Stephens, L.R.C.P.Lond., M.R.C.S., Medical Officer to the Plymouth Public Dispensary.

Vacancies.

Birkenhead and Wirral Children's Hospital, Birkenhead.—House Surgeon. Salary £100 per annum, with board, residence, and laundry. Applications to E. H. Tilby, Hon. Sec., 52, Grosvenor Road, Birkenhead.

Birmingham and Midland Eye Hospital.—Resident Surgical Officer. Salary £100 per annum. Applications to the Chairman of the Medical Board.

City of Liverpool Infectious Diseases Hospitals.—Assistant Resident Medical Officer. Salary £120 per annum, together with board, washing, and lodging at the Hospital. Applications to Edward R. Pickmere, Town Clerk's Office, Liverpool.

County Asylum, Rainhill, near Liverpool.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.

Down District Lunatic Asylum.—Junior Medical Officer (Male). Under thirty-two years of age, with double qualifications. Salary £100 per annum, with apartments, board, washing, attendance, &c. (valued at another £100). Applications to the Medical Superintendent. (See advt.)

Huddersfield Infirmary.—Matron. Salary £80 per annum, with board, lodging, and washing. Applications to Joseph Bate, Secretary, Infirmary, Huddersfield.

Jenner Institute of Preventive Medicine.—Assistant Bacteriologist for the Serum Department, Aldenham, Herts. Salary £200 per annum, with furnished rooms. Applications immediately to the Secretary, Jenner Institute, Chelsea Gardens, S.W.

Macclesfield General Infirmary.—Junior House Surgeon. Salary £70 per annum, with board and residence at the Institution. Applications to the Chairman of the House Committee.

North-Eastern Hospital for Children, Hackney Road, N.E.—House Surgeon. Salary at the rate of £80 per annum, with board, residence, and laundry allowance. Applications to the Secretary, City Office, 27, Clement's Lane, Lombard Street, E.C.

Wolverhampton and Staffordshire General Hospital.—House Physician immediately. Salary £100 per annum, with board and lodging. Applications to Edmund Foster, House Governor and Secrêtary.

Births.

Broughton.—On Oct. 18th, at Batley, the wife of Alfred G. S. Broughton, M.B., Ch.B., of a son.

Foulds.—On Oct. 20th, at Ashlea, Droitwich, Worcester, the wife of Francis H. Foulds, M.R.C.S.Eng., L.R.C.P.Lond., of a son.

Rowland.—On Oct. 22nd, at 16, Bore Street, Lichfield, the wife of Frank Mortimer Rowland, M.D.Cantab., of a son.

Marriages.

Bowle-Evans—Stevenson.—On Oct. 22nd, at St. Patrick's Church, Woolston, Hants, Captain Charles Harford Bowle-Evans, I.M.S., eldest surviving son of J. Bowle-Evans, Esq., J.P., D.L., to Nellie, younger daughter of Colonel W. F. Stevenson, C.B., R.A.M.C.

Blomfield—Olney.—On Oct. 22nd, at St. Mary's, Salehurst, Sussex, Samuel Bartlett Blomfield, B.A., L.S.A., of Hurst Green, third son of Josiah Blomfield, M.D., F.R.C.S., of Peckham, to Catherine (Kitty), only daughter of D. N. Olney, Esq., of Blenheim House, Robertsbridge.

Hassard—Chitty On Oct. 23rd, at St. Peter's Church, Eastbourne, Major Edward Moresby Hassard, R.A.M.C., youngest son of the late Major-Gen. F.C. Hassard, C.B., R.E., to Amy Robinson Chitty, third daughter of the late Alfred Murray Robinson, Esq., Shanghai.

Knox Simond.—On Oct. 22nd, at Holy Trinity Church, Paddington, W. John Edmund Knox, M.B.C.M., East Molesey, son of John Knox, M.D., Bakewell, to Suzanne Lilian, younger daughter of F. F. Simond, Esq., 64, Gloucester Gardens, Hyde Park W.

Lambert—Chattock.—On Oct. 14th, at St. George's Church, Hanover Square, Percy Lambert, M.R.C.S., L.R.C.P.Lond., to Beatrice Fanny, youngest daughter of Mr. Richard S. Chattock.

Pigg-Strangeways—Beck.—On Oct. 23rd, by special license, in the Chapel of Trinity Hall, Cambridge, T. S. Pigg-Strangeways, M.A., M.R.C.S., St. John's College, Cambridge, eldest son of John Thomas Pigg, of Surbiton, to Emily Dorothy, eldest daughter of the Master of Trinity Hall and Mrs. Beck.

Turner—Pritchard.—On Oct. 14th, at St. Peter's Church, Belsize Park, N.W., Bernard Roworth Turner, M.B., B.C.Cantab., of Oundle, Northamptonshire, to Emily Beatrice, second daughter of Urban Pritchard, M.D.Edin., F.R.C.S.Eng.

Deaths.

Alexander.—On Oct. 18th, at Dundonald, Ayrshire, William Alexander, M.D., J.P., aged 87 (retired).

Gale.—On Oct. 21st, in London, from double pneumonia, Frederick William Gale, M.R.C.S., L.R.C.P., of North Cheriton, Somerset, and lately of Kaikoura, New Zealand, aged 34.

The Medical Press and Circular.

Original Communications.

ABSTRACT OF PAPER ON THE CLINICAL HISTORY AND SYMPTOMS OF ONE HUNDRED AND TWENTY CASES OF EXOPHTHALMIC GOITRE. (a)

By GEORGE R. MURRAY, M.A., M.D.CAMB., F.R.C.P.,

Heath Professor of Comparative Pathology in Durham University; Physician to the Royal Infirmary, Newcastle.

OF the 120 cases, 110 were women and 10 were men, showing an exact proportion of 11 to 1. This emphasises the well-known fact that women are much more liable than men to suffer from Graves's disease. Of the 110 women, 57 were married, 1 was a widow, and 42 were single. Of the 10 men, 2 were married, 1 was a widower, and 3 were single.

The age at which the symptoms were first noticed was ascertained in ninety-seven cases. The onset in some cases was insidious, and so the age at which the disease actually commenced could only be fixed approximately. The youngest case was fifteen and the eldest sixty-five at the time the disease developed. These figures show that the greatest liability to the disease exists from fifteen to thirty-five years of age.

There was no history of exophthalmic goitre in either of the parents in any case, although in several cases the disease had occurred in collaterals. Foremost among the exciting causes were sudden or prolonged grief and anxiety or overwork. Of acute illnesses, influenza in three cases, and scarlet fever in one case, had shortly preceded the onset of the symptoms. In one case sudden arrest of menstruation for seven months after a wetting during a menstrual period, and in another hard work in front of a hot furnace causing profuse perspiration, were supposed to be the exciting causes. In only two of the cases did an accident contribute to the development of the disease. In one of them a bundle of wet clothes fell from a height of some twenty feet on to the patient's head, and the symptoms appeared a month afterwards. In the other case the patient fell off a plank into deep water, and was nearly drowned; six months afterwards the goitre appeared, eighteen months later palpitation, and seven years after the accident she had well-marked exophthalmic goitre; her sister, who was with her, went into the water after her; eight years later she also developed a goitre, followed by palpitation and tremors; as, however, her pulse was only 86 when I saw her she is not included in this series.

The onset was usually gradual, though in some cases it was more rapid. The first symptom most commonly noticed was the goitre. Thus, taking eighty-seven cases in which either one symptom or two symptoms simultaneously appeared before the others, an enlargement of the thyroid gland was the first sign of the disease in forty-three. This number, however, includes those cases in which a simple goitre preceded the other symptoms by a distinct interval, and which will be referred to again.

In nineteen palpitation was complained of before the other symptoms were noticed. In four only was the exophthalmos the first symptom, and in the same number either nervousness or tremors were first noticed. In one case rapid respiration was the first symptom which developed. Palpitation and nervousness or other nervous symptom developed at the same time in seven cases, exophthalmos and palpitation in four, goitre and palpitation in three, exophthalmos and goitre in one, diarrhœa and excessive perspiration in one.

SYMPTOMS.—The thyroid gland was enlarged in 112 cases at the time the patient was examined, so that the enlargement of the thyroid gland is a very frequent symptom, which was only absent in 2½ per cent. of my cases. In at least fourteen cases there had evidently been a simple goitre for some years before other symptoms were observed. It follows that in all cases of simple goitre in which surgical treatment is contemplated it is important to make sure that no symptoms of Graves's disease are present, such as tachycardia, tremors, &c., especially as all cases of Graves's disease bear operations badly, and they are therefore, if possible, to be avoided, except in cases where some local condition, such as compression of the trachea, is so marked as to render an operation for the relief of the dyspnœa imperative.

In twenty-seven cases the enlargement was slight, in thirty-six moderate, and in twenty considerable. In one, in which the goitre had been present for thirty-four years it was enormous, the circumference of the neck being twenty-three inches. In twenty-eight cases the size was not defined in the notes, and in eight there was no enlargement at the time of the examination, though in five of these there had been a previous enlargement which had subsequently disappeared.

The enlargement of the gland was generally uniform, the right lobe often being larger than the left, as it is in the normal gland. In only two cases was the left lobe larger than the right. In two cases the right lobe alone was enlarged and in one the right lobe and the isthmus. In four cases an adenoma or cystic adenoma of the isthmus was associated with general enlargement of both lobes. A thrill over the enlarged gland was felt in only fourteen cases, in thirty it was noted as being absent. In thirty-three cases a bruit was heard over the goitre. In twenty-three of these it was systolic in time. In seven there was a continuous venous murmur, which in three became much louder with each systole of the heart. In one other case a venous murmur was heard outside the lateral lobes at the base of the neck. In seventeen cases it was noted that no murmur was present, and in the remaining sixty-eight cases, this point was not noted.

(a) Read in full before the Royal Medical and Chirurgical Society, October 28th, 1902.

The frequency of the pulse was distinctly increased in all the cases varying from ninety up to 200. In no less than sixty-six, or more than half the cases, the pulse was between 120 and 150. In thirty-one of these, or more than one quarter of the cases, it was between 140 and 150 The high frequency of 200 was counted generally during a temporary attack of palpitation, and was not persistent. Great variation was sometimes observed in the same case within a short time. The pulse was usually regular, small, and compressible. Irregularity of rhythm was observed in only eight of the cases, and in one other the pulse was irregular in force, but not in time.

A systolic murmur, heard most distinctly in the second left intercostal space close to the edge of the sternum over the pulmonary area, was present in seventeen cases. In some of these cases this murmur was loud and very rough, almost purring in character. In sixteen cases a systolic murmur was heard at the apex, and in eight a systolic murmur was heard both at the apex and over the pulmonary area as well. As is usual in Graves's disease, pulsation was felt over a larger area than normal in the region of the apex-beat.

Although exophthalmic goitre is the usual name of the disease, exophthalmos is often absent, and this not infrequently has led to the disease being overlooked. In seventy-nine of my cases there was exophthalmos, in three there had been prominence of the eyeballs at an earlier stage, which had subsided before I saw them. In no less than thirty-two cases, or more than one quarter, there was no exophthalmos at all. Von Graefe's symptom, a delay in the natural fall of the upper eyelids when the eyes are directed downwards, was present in thirty-six out of ninety-one cases in which the presence or absence of this symptom was specially noted. Retraction of the upper eyelids, commonly known as Stellwag's sign, was observed in forty-seven cases; in twenty-nine it was absent, and in the remaining forty-four no mention of it was made in the notes. I find that in thirty-three cases the exophthalmos was present alone, in nine retraction of the upper lids with widening of the palpebral fissure as a consequence occurred alone, while Von Graefe's symptom was present alone in only one case. All three symptoms were present together in twenty-seven cases, in eight exophthalmos and Von Graefe's system occurred together without Stellwag's sign, and in eleven exophthalmos and Stellwag's sign without Von Graefe's symptom.

A fine regular tremor of the hands, which is best seen when the arms and hands are extended in front of the patient, is one of the most constant symptoms in exophthalmic goitre. This was present in 111 cases. In some of these it was very well marked, in others slight, and in some it was not observed on every occasion.

A peculiar mental condition of nervousness is a common symptom in exophthalmic goitre. Such patients are generally in a state of suppressed excitement. In seventy of my cases this condition was noticed as present, and in three cases it was absent, in the remaining forty-seven no special note was made as to the mental state. In some cases the patient's temper was irritable. Some were very emotional and easily perturbed by trifling events, such as would not upset their equanimity in health. In some cases restlessness was a marked feature, and many patients are remarkably insensitive to cold. Various abnormal mental states were also observed.

Weakness of the legs was complained of by fifteen patients. Five of them stated that the legs felt weak, as if they would give way while walking. Seven complained that the legs actually gave way, and five of these actually fell or were unable to walk at the time in consequence of this sudden loss of power. One patient who fell when she was out walking was unable to rise again without assistance.

The skin is frequently moist from an increase of insensible perspiration or from actual sweating. In seventy-six of my cases there was unusual dampness of the skin, and in fifty-five of them there was no sweating. More or less pigmentation of the skin was observed in twenty-two, or rather more than one sixth of the cases. The brown pigmentation was most marked on the exposed portions of the skin of the face, neck, and hands. In several cases it was especially marked on the eyelids and around or beneath the eyes. In one the outer edges of the areolæ and the front of the leg showed the pigmentation most markedly. In one case there was general diffuse pigmentation of face, neck, forearms, and hands, with darker freckle-like patches on the backs of the hands and forearms. In one case the patient used formerly to suffer greatly from chilblains, which disappeared when she developed exophthalmic goitre. As she improved, however, the chilblains began to return. Loss of hair was noted in ten cases. This generally occurred in the earlier or more acute stages of the disease. The hair generally grew again as the other symptoms subsided. In two of these cases the scalp became almost entirely bald, and in one this was accompanied by loss of eyebrows and eyelids as well.

Increased frequency of respiration was observed in some cases, but did not as a rule give rise to any discomfort.

Variations in the appetite were noticed in eleven cases; in four of these it was diminished, and in seven it was increased, or there was actual craving for food; in three others the appetite was good. Thirst was complained of in four cases. Vomiting occurred in seven cases; in two of these it was severe and continued, and largely contributed to the fatal issue. The most frequent symptom was diarrhœa. This usually occurred in the form of short attacks of painless diarrhœa of one or several days' duration. These attacks often started suddenly and terminated in the same manner. This liability to diarrhœa was noted in thirty-five cases, or rather more than one-fourth of the total number. Constipation was present in eight cases. In four cases there was increased frequency of defæcation. This symptom must be distinguished from diarrhœa, as it may be mistaken for it by the patient. The bowels act twice or thrice each day, but the motions are quite normal in character.

The condition of the urine was, unfortunately, only noted in nineteen cases. In four of these a trace of albumen was found, and sugar was found in three; in one of these there were 15 grains to the ounce of urine, and in another 40 grains.

In the 110 cases in women some irregularity in menstruation was noted in twenty-three cases. Amenorrhœa for periods of varying lengths, from five months to eight years, was present in ten cases. In two cases menstruation occurred too frequently, and the loss was also excessive.

Wasting is a common symptom, and some loss of flesh was noted in forty-five of my cases.

The course of exophthalmic goitre is generally slow and protracted, and runs so differently in different cases that it is difficult to follow, and prognosis is often uncertain. Even in the most favourable cases a patient after an attack of exophthalmic goitre seldom returns quite to the normal condition. In a considerable number there is a practical recovery, so that the patient feels well and complains of nothing, but a careful examination often shows that the pulse is still unduly frequent and excitable, or the thyroid gland remains slightly enlarged, or there is rather a staring expression or some general nervousness. Out of forty of my cases in which the patient was seen from time to time, or information obtained as to the course of the disease, seven died, two remained stationary, and thirty-one progressed favourably. Of these thirty-one in which improvement took place, nine practically recovered, though two of them afterwards had partial relapses, eight were greatly improved, and fourteen improved to a certain extent. In none of my cases was exophthalmic goitre followed by myxœdema.

Treatment.—If the symptoms are severe, absolute rest in bed for three or four weeks is essential with, in cases in which the nervous symptoms are predominant, a course of what is often known as "Weir-Mitchell treatment."

In less severe cases it is well to regulate the patient's mode of life as far as circumstances permit of it, providing for ample repose, alternating with gentle walking exercise, which may be gradually increased from half a mile up to three or four miles a day, according to the progress made. As cases of exophthalmic goitre do not feel the cold easily, and are not liable to catch cold, they can spend much time out of doors nearly all the year round.

Electricity is most useful in many cases. The faradic current may be employed easily and efficiently by a method which was first described to me by Sir Victor Horsley. Two flexible metal electrodes, about four inches long and two inches wide, covered with wash-leather, and connected by a small strap and buckle on each side, are moistened and accurately applied to the neck. One electrode is placed in front over the thyroid gland, and the other over the back of the neck; the straps are then tightened so as to keep them in position. The electrodes are connected with the secondary coil of a small dry-cell faradic battery, and sufficient current is turned on to produce a distinct prickling sensation. The faradic current should be applied in this way for an hour each night and morning for several months. Not only do patients feel relieved for a time by each application of the current in this manner, but I have seen steady improvement take place under this continued use. No special diet is usually necessary.

Medicinally, belladonna was frequently prescribed, but with doubtful results. To be of service in exophthalmic goitre any line of treatment must be steadily maintained for some weeks or even months, and patients often dislike to continue taking belladonna in sufficient doses to produce physiological effects. Convallaria has proved useful in cases in which the frequency of the pulse has been very high, and is more effectual in lowering the pulse rate than other cardiac tones. Bromides are useful in cases in which there are marked nervousness and tremors. Arsenic is useful in nearly all cases, and may be combined with other drugs with advantage. The best results are obtained by giving small doses of three or four minims of Fowler's solution three times a day for a month or two, or for the first three weeks of each month for five or six months.

Of the animal extracts thymus and supra-renal tablets have both been of service. Thyroid extract is harmful, as it often exaggerates the symptoms, and should not be given in exophthalmic goitre.

The Bathgate Prize of the Royal College of Surgeons, Edinburgh, has been awarded to Mr. John Macmillan Campbell.

WHOOPING-COUGH. (*a*)

By A. F. VOELCKER, M.D., F.R.C.P.,

Assistant Physician and Lecturer on Pathology at the Middlesex Hospital, &c.

The Goldsmiths' Company have, by their handsome liberality, enabled this hospital to open a ward of sixteen beds into which cases of whooping-cough are admitted for treatment. This ward has now been open twenty months, and it has been my good fortune to have had charge of the ward all the time. In bringing before you some of the results of my observations on the cases under my care I must claim your indulgence for a repetition of many facts well known to many of you; and if after all I am not in a position to answer the question which seems to rise spontaneously to the lips of so many people, "What is the cure for whooping-cough?" yet I hope to be able to point out to you some of the factors concerned in the successful treatment of the disease, some of the complications and their import, and some points which have proved of practical utility in the diagnosis of this disease. At the outset I should like to insist on an important point, and that is that the remarks I am about to make refer to the special cases under my care, and not to cases of whooping-cough as a whole. Owing to the infective nature of the disease, and to the great amount of attention which severe cases of whooping-cough require from the nursing staff, and from the fact that there are only two hospitals in London into which cases of whooping-cough are admitted as in-patients, the cases which come under our observation are naturally very severe ones, and in the greater number of instances are, at the time of their admission, suffering from some complication, most commonly broncho-pneumonia. That whooping-cough is infectious is well known, but from the fact that we only take in the severe cases it is rarely that we have as in-patients more than two children of one family at the same time. The infectivity of whooping-cough cannot be very great, because we find that although cases which have been in for some time and have then developed undoubted whooping-cough are sent to us from the general wards, yet we have not had more than one case ever sent from any one ward. If the disease had spread in the way in which we find measles or diphtheria spreading we should have had more cases sent in from one ward. Another point with regard to the infective nature of whooping-cough is that while the nurses do not nurse in any other ward, yet the sisters and nurses of this ward have their meals in common with the other sisters and nurses of the general hospital. In spite of this we have had no case of whooping-cough arising in the hospital which we could trace to infection conveyed by any one in the hospital itself. Those points show us that although whooping-cough is infective, yet with suitable hygienic precautions, that is to say, plenty of air space and good ventilation and ordinary cleanliness, it is possible to successfully isolate cases of whooping-cough.

The diagnosis of whooping-cough does not often come before us as a very practical difficulty. The cases that are most likely to be mistaken for whooping-cough are cases of either enlarged bronchial glands pressing on the trachea or main bronchi, cases of bronchiectasis, cases of pleural effusions, cases of enlarged tonsils and adenoids, and occasionally a case of laryngismus stridulus. I do not propose to go into the differential diagnosis of whooping-cough now, but there are certain points in connection with certain symptoms of whooping-cough which are perhaps worthy of your attention.

(*a*) Abstract of a Lecture delivered at the Hospital for Sick Children, Great Ormond Street, June 5th, 1902.

First of all there is the cough. If the cough is paroxysmal and unattended by abnormal physical signs in the chest and pharynx, the probability is that the case is one of whooping-cough. If a cough is brought out by psychical disturbance, or as a result of mechanical stimulation of the pharynx, and then that cough is paroxysmal, the case is probably one of whooping-cough. The practical point is, that when in doubt about a case of whooping-cough, never neglect an examination of the throat. The more you have to do with children the more you will look at their throats. When in doubt as to the nature of a cough, or if you have reason to suspect the presence of whooping-cough, examine the child's throat and use a spatula. Do not be in too great a hurry, and finish up with a little stimulation of the back of the pharynx with the spatula; this will very often bring out a characteristic paroxysmal cough, or even induce a whoop which had hitherto been latent or unnoticed. It is said that the cough of whooping-cough is more frequent at night. Our experience in the ward is that it is not. The cough of whooping-cough, as seen in private practice, undoubtedly does show itself most commonly towards evening, and the reason is that in all probability the child is tired, and, feeling ill, resents being undressed, cleaned up, and put to bed. It is probably partly the mental and partly the physical upset that make the cough more frequent. Another point that has come out with regard to the frequency of whoops and coughing is that while the number of individual whoops varies tremendously—in the marked cases we have 300 to 400 whoops in the twenty-four hours—yet even in these very severe cases the number of paroxysms of coughing rarely exceeds twenty in the twenty-four hours. In no single case have as many as thirty paroxysms of coughing been noted in the twelve hours. It must be remembered, of course, that the frequency of the cough is no measure of the severity of the attacks of coughing. Next to the coughing and the whooping is the question of expectoration. The most common conditions which cause children under twelve years of age to expectorate are whooping-cough and bronchiectasis. In bronchiectasis the expectoration is most abundant in the early morning, on the patient first getting up; and it is frequently, but by no means universally, offensive. In diagnosing bronchiectasis, besides the physical signs in the chest, a very important point is the question of clubbing of the fingers, and a large number of cases of bronchiectasis occur in children who are the subjects of syphilis. Spitting, in the case of a child who has a cough, is very suggestive of whooping-cough. The mucus is very thick and tenacious, and it clings about the mouth in a striking manner. Hæmoptysis, which is not a common phenomenon in children, is met with fairly frequently in whooping-cough, although in the cases under our observation in the hospital it has been by no means common. Hæmoptysis in pulmonary tuberculosis in children is, as you know, rare. We have had in the whooping-cough ward one fatal case of hæmoptysis in a child with whooping-cough, in whom there was pulmonary tuberculosis, the lungs having been extensively destroyed by the disease. Vomiting is a frequent symptom of whooping-cough, and is usually initiated by a cough. A combination of coughing and vomiting is very suggestive of whooping-cough, though by no means diagnostic of it. In bronchiectasis, in cases of enlarged tonsils, and in cases where we have enlarged bronchial glands, we may get co-existing coughing and vomiting. Vomiting occurred in over 90 per cent. of the cases of whooping-cough under our observation. Sublingual ulcer is a very suggestive sign of pertussis. The sublingual ulcer is an ulcer situated at the frænum, where the frænum joins the under surface of the tongue, and is usually single. It varies in size. It may be three-quarters of an inch long by half an inch broad. It may be only the size of a lentil, or even smaller. But although usually single they are sometimes multiple. The ulcer is the result of mechanical injury. It is said only to be present in children who have cut their lower incisor teeth. This is not absolutely correct. I have seen cases of sublingual ulcer in children who had no teeth at all. The explanation in these cases is simply that we have the under surface of the tongue and frænum markedly stretched over the alveolar margin; and although we have not a tooth there, we have sufficient stretching to cause laceration, and the constant movement prevents the healing. An interesting point about a sublingual ulcer is that it is very rarely painful; if we remember how painful aphthous stomatitis is in a child, it is curious to see a big ulcer under the child's tongue, and yet the child practically free from pain. Age is an important factor in connection with the occurrence of the ulcer. It is extremely rare in infants under one year of age. In thirty-five cases in my ward in which it was present, only one child under one year of age presented it. This was in a child who had cut its lower central incisor teeth. It occurred in twelve cases between one and two years of age; in seven between two and three; in five between three and four; in six between four and five, and after this its occurrence was rare, but the majority of children in the ward are under six years of age. It must not be concluded that in the bigger children we did not get them; the point is that we did not see so many big children in the ward. Is sublingual ulcer pathognomonic of pertussis? Personally, I should be inclined to attach very great importance to the presence of a sublingual ulcer, though I cannot say that it never occurs in any other condition. Subconjunctival hæmorrhage was not at all frequent. Out of 161 cases we have only had three cases in which subconjunctival hæmorrhages were noticed. The hæmorrhages are not pathognomonic of pertussis, although suggestive. With regard to the whoop, "One swallow does not make a summer," and one whoop will not make whooping-cough. We get cases of whooping-cough without any whoop, and we may get a whoop without any whooping-cough. In very young infants it is rare to get a whoop. But after six months of age whooping is not so infrequent, and we have had some very severe cases of whooping-cough in infants under one year of age. I have known enlarged tonsils, enlarged bronchial glands, bronchiectasis, pleural effusions—either purulent or serous—accompanied by an occasional whoop; and I have known the crow of laryngismus stridulus mistaken for the whoop of pertussis. The next point that has struck me is the influence of a rise of temperature on the frequency of the whoop. In a very large number of cases, when the temperature rises the frequency of the whoop falls, and when the temperature falls the whooping increases in frequency. Another point noticed has been this: Occasionally cases are admitted with a temperature of 102° or 103°, with signs in the chest which would justify the diagnosis of consolidation from pneumonia. After the child has been in the ward twenty-four to forty-eight hours the temperature falls and the number of whoops is lessened. These cases are interesting, because I believe they indicate collapse of the lung, and in my experience the diagnosis of collapse of lung from pneumonic consolidation is very difficult. I cannot state definitely any means by which I can tell the one from the other; but the fact that these cases suddenly get well without showing those signs of resolution which the pneumonic cases show, and the fact that the dulness clears up very quickly, indicate the nature of the case. Another point is the marked improvement which children show when they are taken into the hospital.

With regard to the complications of whooping-cough, I have pointed out that the majority of cases are admitted with some complication already present. By far the most frequent complication is broncho-pneumonia. Out of 161 cases admitted we had fifty-six in which either broncho-pneumonia or lobar pneumonia was, in our opinion, present. The gravity of this condition may be imagined from the fact that twenty-eight, or 50 per cent. of them, proved fatal. Bronchitis was a marked feature in eighteen cases, but of these only one terminated fatally. Pulmonary tuberculosis, usually associated with widespread tuberculosis, was present in fifteen cases of which fourteen proved fatal. Bronchiectasis was present in two, empyema was present in only three cases, and one of them proved fatal. Serous pleural effusion was present in three cases, and all of them recovered. Marked distension of the lung, which is often spoken of as acute emphysema, was present in two cases in sufficient degree to constitute a marked feature of the case, although it is present in a large number of cases as a temporary condition. So-called surgical or subcutaneous emphysema was present in two cases, both of which terminated fatally. Tetany was present in four cases, one of which proved fatal long after the condition of tetany had been recovered from, as a result of an attack of broncho-pnuemonia. Another little point which is not incidental to whooping-cough, but I think is an important practical point, is that ischio-rectal or gluteal abscess occurred in five cases, and from their occurrence we have learnt to look out for them as a cause of a rise of temperature which we could not explain in any other way. Under the head of convulsions I do not include those which were symptomatic of tuberculous or non-tuberculous meningitis or other actual organic disease of the brain. Convulsions were present in nine cases, and in six of these death occurred. Epistaxis was present in five, hæmoptysis in ten, three of which were fatal; otorrhœa in four cases, and we had one case in which aphasia, the result probably of thrombosis, occurred. In regard to treatment, the drugs which I have used have been antipyrin, belladonna, citrophen, bromoform, heroin, glycerine of carbolic acid, bromide of potash and belladonna, creosote, chloride of ammonium, carbolic spray and thyroid extract—and I need not apologise for using thyroid extract, because we had a child with malignant disease of the kidney, and we thought we could give it thyroid extract in the hope of influencing the new growth, but it had no effect in diminishing the whoop. Lately we have been going back to a very old practice, namely, the use of antimony. A Swedish doctor, who was over here recently, told me he knew of a specific which was much used abroad, and asked me to try it. Its composition is antimon. sulphurat. rub. gr. ⅙, extract. hyoscyami gr. ¼, pulv. glycyrrh. gr. ¾, pulv. gum. acac. gr. 2½, pulv. sacch. alb. ad gr. x. We tried it, and one case has done well on it, but further experience has not impressed me with its value. Besides those we have tried more or less generally carbonate of ammonium, strychnine, phenacetin, guaiacol, salol, and so on. I propose to summarise shortly what our experience has been. Antipyrin was tried in eleven cases. There was distinct improvement following its administration in two of them. In three there was slight improvement; and in six it was doubtful if the drug had any good effect. Belladonna was given in seven cases, and in three decided improvement took place. In two the patients seemed to improve; in two the effect was doubtful. Citrophen was used in ten cases, in five distinct improvement took place, in one there was slight improvement, and in four there was little or no benefit. Bromoform was used in eleven cases. Its use is not unattended with danger on account of its oily nature and high specific gravity. We have had one case of an out-patient admitted with symptoms of acute bromoform poisoning, and one case has occurred in the ward where the intoxication was mild; in both cases the symptoms followed shortly after the administration of the last dose in the bottle. Bromoform should be dispensed in a dark bottle kept in the dark, and the quantity of the mixture in the bottle should not be too great, so that the risk of an overdose of the drug in the later doses is diminished. Directions should be given that the bottle must be well shaken each time before pouring out the draught. The dose we have employed has been from 3 to 5 minims three to four times a day. In two cases there was distinct, in two cases slight, and in seven cases no definite improvement. Glycerine of carbolic acid was used in fifteen cases; in one case there was distinct, in three slight, and in eleven there was no appreciable benefit traceable to its use. Creasote was tried in seven cases; in two there was distinct, in one slight, and in four no definite improvement. The drug was given internally and as a vapour. Chloride of ammonium was tried in the hope that the drug might cause the secretion to be less viscid, and so easier of expulsion. Heroin was only tried in two of the cases I have analysed for you to-day, though I am giving it a more extended trial at present. In one of these cases when pushed to doses of one-thirtieth of a grain every six hours it was very beneficial. In the other case it was of no benefit. Carbolic acid spray was used in four cases with slight improvement in two, and none in the other two. Bromide of potash and tincture of belladonna were tried in six cases; one benefited distinctly, two slightly, and in three there was no improvement. From this *résumé* of the results of treatment by certain drugs I am afraid that I cannot claim to have discovered or even confirmed the existence of any drug which could be called a specific for the disease. During convalescence nothing has proved so useful as cod-liver oil and steel wine.

Clinical Readings and Practices.

II.—HYDROPS BRONCHIALIS. (*a*)

By the late

Sir B. W. RICHARDSON, M.D., F.R.C.P., F.R.S.

Definition of Hydrops Bronchialis.

In some of my experiments on the production of anæsthesia in the lower animals I observed that during the narcotism death was caused from a very simple circumstance. There was an accumulation of watery secretion in the bronchial passages of the animal, and from the obstruction to the entrance of air asphyxia resulted, which ended in death. I drew attention to this mode of death in one of my reports to the British Association for the Advancement of Science in the year 1871, and after this I began to observe that precisely the same is occasionally witnessed during disease in the human subject. I drew out a practical note upon this matter, which will be found in the *Asclepiad* for 1884, pages 253-55.

(*a*) We published some "Clinical Readings and Practices" in 1888, written specially for this Journal by the late Sir B. W. Richardson, the numbers containing which have been long since out of print. So much interest was taken in these papers that quotations from them by past and present writers has determined us to yield to the requests of several of our subscribers to reprint them. No. I. was republished in our last issue.

A term applied by people generally to the phenomenon in its later stages is extraordinarily terse and striking. The term is "*death rattle,*" a term which invariably denotes, to the common mind, the prelude to death. The prognosis is correct in the large majority of cases. I have very rarely known it wrong. Death rattle is the loud auscultatory sound indicating the conditions of disease now under consideration. Everyone who has the ordinary power of hearing can hear it. But the trained ear of the physician can often be led to detect the sound or rattle a long time before it is distinguished by those less gifted in diagnostic art.

The accumulation of water in the bronchial passages is aided by condensation, or, perhaps it were more correct to say, is aided by any obstacle to the evaporation of water from the lungs. Two such obstacles require to be specially noticed. The first is the accumulation of water vapour in the air of the room in which the sick person lies; the second is the reduction of animal heat in the body of the patient himself by which the radiation of water vapour by the natural warmth of the body is reduced.

The cases of disease in the human subject in which this condensation occurs are most commonly those of asthenic bronchitis; of the later stages of pneumonia; of narcotism during uræmic coma; of coma from apoplexy; and of coma from narcotic poisons such as chloral hydrate, nicotine, or morphia. In very cold and damp weather the condensation may be a cause of death during the narcosis produced by chloroform, methylene, or ether, and although I do not recollect any record of a case where it produced death in man, I have known it to produce the most alarming symptoms in the lower animals, during experiments with anæsthetics, and we then have seen it cause death. The general symptoms indicating Hydrops Bronchialis, the name I would apply to this condition, are those of obstruction to the breathing, loud and watery bronchial râles, and coldness of the body, beginning at the feet and extending upwards until the temperature of the whole body is reduced, and the coldness of death becomes universal.

It is always to be remembered that when once the condensation has commenced the progress to death goes on at compound speed. The minute bronchial tubes are soon filled and as the air finds itself shut off from the blood the respiratory changes are more and more impeded. The condensation is proportionately increased and the asphyxia is advanced. At last, as I originally expressed in describing this condition, the sufferer is literally drowned in his own secretion, the death being by pure asphyxia.

Symptomatic Importance in Disease.

As hydrops bronchialis is a symptom coming on late in the course of dangerous diseases or of toxic accidents, it is too often accepted as a mere prelude of death, and is allowed to run its course without attention. It is my object in this essay to rescue it, if I may so say, from this position. The accumulation of water in the bronchial passages may often be the turning point to death, the very turning point from life to death. It is, therefore, most important in all cases in which it may be expected, to be on the look out for it, and to take every precaution to prevent its making a commencement.

Treatment, with Illustrations.

There are two means, the one major, the other minor, by which the condensation may be held back in cases in which it is expected. The major measure consists in the management of the room in which the patient is lying. The air of the room must be kept warm and dry. It is quite impossible to over-estimate the necessity of obtaining dryness of the air. This fact is well shown by a side observation. In administering chloroform on a cold, damp day it is exceedingly difficult to produce quick anæsthesia. All the stages are prolonged, and very troublesome symptoms are developed. The dangers are increased: the throat and mouth of the patient are charged with fluid secretions; the narcotism is sustained with difficulty; and the recovery is greatly prolonged. In this instance the difficulty is easily read off on purely physical grounds; the presence of moisture in the atmosphere has interfered with the diffusion of the vapour of the chloroform on the one hand, and has interfered not less with the evaporation of water from the bronchial surface on the other. Thus the presence of water vapour in the sick room plays a leading part in disease, for good or for evil. In the forms of disease in which hydrops bronchialis is to be feared an excess of water may just turn the scale.

Let me now give one or two illustrations of a practical character. I was called hastily to see an aged man who was suffering from subacute bronchitis. The symptoms had not been very severe, but had been rather complicated with those of cardiac intermission. The breathing now had become embarrassed, and the bronchial tubes were filling with fluid. There was a soft watery râle over the whole of the chest. The air of the room in which the patient lay was saturated with water vapour. I tested the humidity by Lambrecht's hygrometer, and found complete saturation of the air. The room itself was small and not very well ventilated, it contained too many persons, and, worst of all, it was plied with vapour water from what is not inaptly called a "bronchitis kettle." The temperature of the patient had already become lowered to 98° Fahr., and here was he lying in a vapour bath in a room badly ventilated, and, still more seriously, with the temperature of that room at 55° Fahr. It would not easily be possible to invent for purposes of experiment an apartment or chamber in which the conditions were more favourable for the production of *hydrops bronchialis*. Every physical state favoured condensation everywhere. The looking-glass was dim with moisture; all metallic and other bright objects were bedewed with moisture. If anyone had taken out of that room a woollen or linen article and had spread it before the fire it would have been called damp, and the prudent housewife would have declaimed loudly enough against its use. But at this supreme moment the subject of damp was never, for an instant, taken into consideration. The bed of the patient was damp throughout, so that the evaporation from his cutaneous surface was almost as much obstructed as that from his lungs. This failure of cutaneous action added to the pre-existing evil, and combined with the feebleness of the circulation incident to the disease and the cooling of the body, rendered recovery next to impossible under the existing circumstances.

My first care in this case was to order away the "bronchitis kettle"; to have everything removed from the room that would hold damp; to insist that a good fire should be made up; and that there should be fewer persons in the chamber. In a very short time the temperature of the room was brought up to 65° Fahr., and the humidity of the air was brought down to 70°. I next recommended that the bed clothes of the patient should be changed, even to the bed itself. A fresh mattress and a light feather bed were well dried and warmed by the fire, and were made to replace those upon which the sick man had rested for many days. Blankets, sheets, and counterpane were in like manner removed and replaced by dry warm substitutes; whilst a German quilt which, from the moisture it had absorbed, had become weighty, was sent away with as little ceremony as the rest. The reform was extended to the handkerchiefs used by the sufferer; these were constantly changed, and the patient was directed to breathe through a handkerchief heated at the fire at frequently repeated intervals. In a period of an hour the condition of the air of the room was changed altogether; the air was rendered sweet, and, above all, its dampness was removed.

To anyone who understands the simplest principles of evaporation and of condensation, or who thinks over the way in which dew is produced, it will be at once clear that in the condition in which the patient alluded to was placed, the simple plans named above were directly calculated to give relief. I am sorry to say that they did not appeal strongly to the judgment of the friends of the sick man. They had sent for me to cure the sick man, and lo! I merely directed them to do what any nurse could have proposed and carried out. It was quite necessary that I should prescribe as well as direct, a suggestion I at once adopted; and this brings me to the second portion of the treatment of hydrops bronchialis to which I have referred, and which may be called the medicinal treatment.

In the choice of a medicinal remedy I proceeded precisely as if the patient were suffering from loss of blood or from a watery discharge from the bowels I prescribed a mixture containing in each dose ten minims of dilute sulphuric acid with five minims of tincture of nux vomica, in one fluid ounce of infusion of roses. At the same time I advised a fair amount of food. Minced meat—fowl or fish—bread sauce with essence of beef, and fruit - grapes—in small quantities. Thin fluids, of all kinds, were to be avoided altogether for a few hours.

The treatment thus proposed was carried out faithfully, and answered beyond my expectation. Within four hours the bronchial râles had ceased, the surface of the body had become warm, the breathing was free, and the immediate serious symptoms were entirely removed. From this attack the patient had a complete recovery. His friends attributed the success of the treatment to the medicine by which they meant the acid mixture, and considered the change in the room as a mere detail. Such is the effect of long-continued beliefs in nostrums on the human mind.

I do not dispute that the astringent mixture had a beneficial action. I should not have prescribed it unless that conviction had been strong in my mind. At the same time I am quite sure that the medicine played a secondary part, and that if the conditions of the patient's room had been allowed to remain the same all the medicines in the world, by whomsoever prescribed, would not have prevented the condensation of water vapour in the bronchial passages, nor the fatal asphyxia incident to unchecked hydrops bronchialis, an opinion which recalls to my mind a remark which I made many years ago, and which cost me a severe criticism at the moment, "Give me the management of the fire and the window and, in nine cases out of ten of acute disease, I will determine the fate of the patient."

In the case above named this truth stands out well. No medicine which I could have brought into that sick man's room could have stopped the deposition of dew or moisture on the face of the looking glass; and, in like manner, no medicine which I could have administered to the sick man himself would have prevented the deposition of water on his cooling bronchial surface.

When chloral hydrate had just come into use I was summoned to see the first case of poisoning by it. A retired Indian medical officer, who had become weary of life, determined to retire from life in the easiest possible manner. He had attended one of my lectures on chloral hydrate, and had seen how gently animals slept to death from a dose of it. Thereupon, in a melancholy mood, he obtained half an ounce of the hydrate, went to bed, put a quantity equal to 180 grains in half a tumbler of brandy and water, and composed himself to sleep. He was discovered in deep narcotism with the evidences of what he had done by his bedside. On being summoned I found the coma profound, but the surface of the body was warm and the circulation was firm and steady. There was but one danger, namely of hydrops bronchialis, and that was imminent. Moist watery râles, amounting almost to death rattle were to be heard all over the chest, and even in the mouth and fauces there was an accumulation of fluid which set up reflex action, and gave rise to cough. I had already learned from my experiments on the inferior animals with chloral that during the deep sleep produced by the narcotic, hydrops bronchialis was the condition which was most to be feared. I had also learned, from the same line of observations, that if the sleeping animals were only kept in a warm dry air, so as to secure a free evaporation from the lungs, they would always recover if the dose were not so large as to destroy life by an overwhelming shock. I therefore felt less alarm than those around me. Backed by experimental knowledge I felt convinced that if I could only prevent the patient from being drowned in his own bronchial secretion he would weather the storm. The best precautions were, therefore, taken to meet the physical difficulty. The temperature of the room was raised quickly to 75° Fahr., and the patient was brought as close to the fire as was possible. In this state he was kept for twelve hours, being fed at times through the nostrils, by a long stomach tube, with warm milk and water, to which beef tea was added. Gradually consciousness returned, and a very good recovery was made.

Now here, again, was a case in which the prevention of hydrops bronchialis absolutely saved the life. Long before I arrived at the bedside of the narcotised man the time had passed for resorting to any other measures, such as the use of the stomach pump or the administration of an emetic. The depth of the narcotism indicated that the soluble narcotic had diffused through the whole of the nervous system; and if any attempt had been made to produce vomiting it would not only have been useless, but would have been attended with actual danger from choking and suffocation. To prevent hydrops bronchialis was therefore the only chance of saving life, and how well it answered the history of the case itself records.

In a lecture on death by drowning and cold which formed one of my experimental courses I related an instance of drowning that in the most telling manner illustrates the simple yet practical lesson now before us. The captain of a vessel with some of his sailors was brought on board his ship insensible, from immersion in the sea. He and they were all looked upon as past hope. The captain was carried to the most convenient spot, where every effort, as it was said, was made, by artificial respiration and other means, to save his life. The means were of no avail; death took place in spite of them. But (and surely the irony of fate was never more fully vindicated) the sailors who had shared the same danger with the captain, and were equally insensible, were carried straight to the engine room, where they all "came to," and made rapid recoveries. The dry heat of the engine room produced quick evaporation of the water which had accumulated in the lungs, and life was restored without any further artificial aid.

One other class of case occurs to me before I close the record of illustrations. We hear in London, occasionally, of instances of what is called "fog poisoning." The one and only case I have seen that could be considered as of this kind was really one of hydrops bronchialis. The patient was a delicate man, a member of our own profession. I had often met him in consultation and in other matters, and he had many times complained to me of suffering during cold and damp from asthmatic breathing and cough. One evening I called upon him in order to visit a patient with him to whom he had summoned me professionally. The night was foggy, and he was rather anxious about the exposure to the fog; he nevertheless went out still later, when the fog was much denser, to visit another patient, and, returning home, was soon obliged to go to bed owing to the obstruction in his breathing. In a few hours he was involved in hydrops bronchialis, and died from the resultant asphyxia.

I pass now to one or two points of practice before I conclude.

Testing the Air for Moisture.

If the view I have stated above be correct it becomes of practical moment to test the air of the sick room in order to ascertain how far it is charged with the vapour of water. In 1870 I invented a clinical meteorological cabinet, which was made for me by Messrs. Horne and Thornthwaite, and which is very compact and convenient. It contains an aneroid barometer, a dry and wet bulb thermometer, and a chamber for holding ozone papers. The whole is very complete, and for the hospital ward is indispensable, if correct observations are to be carried on. But for daily practice the hygrometer of Lambrecht will be found quite sufficient, and as its hygrometric scale can be read off by the nurse, without calculation, as easily as the thermometer, it runs well, in practice, side by side with the thermometer. Lambrecht's instrument is an ingenious modification of De Saussure's. It has lately been introduced by Mr. Schomberg, of Berlin, and is made in this country by Messrs. Casella, of Holborn. The instrument is small and convenient. It is a cylinder two inches in diameter and three inches high, supported on a firm base, so that it may be placed safely on a shelf or table. The cylinder is perforated, that the air may traverse it freely. Within the cylinder a little bundle of hairs stretches from the top to the bottom of it, and on the top surface there is a dial plate, divided into 100 degs., and furnished with a needle, which, like the hand of a clock, points to the figures and indicates the degree of humidity. The humidity is determined by the hydration of the bundle or column of hairs. If the air be dry the point of the needle is deflected towards or to zero; if the air be moist the needle is deflected towards or to 100°. So delicate is the test that the simple experiment of breathing once or twice through the cylinder is quite sufficient to indicate a change of the needle on the dial.

Impressed with the importance of regulating the amount of water vapour in the sick room, I have, for two years past, used this hygrometer in practice, with, I am sure, good effect. It is a very simple instrument to use, and a nurse soon learns to watch it, and record its readings. A few simple rules may, nevertheless be supplied for the guidance of those who may not be familiar with the working of the instrument.

Rules.

1. The air absorbs moisture according to its temperature, and the warmer the air is the more moisture it can contain. For example, air at a temperature of 80° Fahr. can absorb as much as 10·9 grains of water vapour in each cubic foot, while at a temperature of 50° Fahr. it can only hold 4·1 grains, and at 32° only 2·1 grains. When the air has absorbed all the moisture it is capable of containing at its temperature, it is then said to be saturated.

2. Usually, the air is not saturated, but only contains a part of the moisture which at its existing temperature it could hold in suspension, and that part is, in ordinary practice, expressed in a percentage as the relative humidity or moisture of the air. For example, if the temperature of the air were 80° Fahr., and the relative humidity were 50° Fahr., such an air would be half saturated. It would contain 5·5 grains of vapour in one cubic foot; but if fully saturated it would contain 10·9 grains. In order to saturate the air with 5·5 grains of water vapour the temperature of the air would have to be brought down to a degree of 58·5° Fahr. It would then be completely saturated with moisture—dew point.

3. There is probably no form of disease that can, in any degree, be benefited by an air saturated with moisture at a low temperature. In some diseases, such, for instance, as those in which the vapour bath is thought to be useful, air saturated with water at a high temperature may be of service. That is a question yet to be answered. But we may be satisfied, for our present study, that whenever *hydrops bronchialis* is to be expected, a cold air saturated with vapour of water is always a true danger. The rule then is to raise the temperature and to reduce the moisture.

4. In carrying out this rule it is always safe to raise the temperature of the air to 64° Fahr., and to dry the air to 30° on the hygrometric scale. If the air at this point of dryness does not produce cough or sense of irritation in the throat of the patient, it may be raised in temperature even to 75° Fahr., and may be deprived of moisture still further, even down to zero, for a short time.

Modes of Drying the Air.

As a common practice the air of a room may be dried to the degree required by means of an ordinary fire, unless the outside air be heavily loaded with water vapour. If difficulty arise from this cause the process of drying the air may be expedited by placing in the room, in one or more places, an ordinary spittoon of earthenware, into which a few ounces of strong sulphuric acid have been poured. It is remarkable how quickly the air is dried by this simple plan, and, as the vessels holding the acid can be removed easily without spilling the acid, there is no occasion for carrying the method a minute beyond the point that is required. Practically, an air warmed to 64° Fahr., and dried to 30° on the hygrometric scale, is a good standard air for the prevention of hydrops bronchialis. In late stages, when the bronchial passages are surcharged with water, it may be necessary to raise the temperature to 70° or 80° Fahr., and at the same time to reduce the amount of water, but the standard given above is that on which to depend as the medium.

In cases in which it can be obtained for warming the sick room, the stove called the Calorigen—invented by Mr. Webb George—is exceedingly good. This stove, which can be heated either with coal or gas, brings the air through a tube into the sick room, allows it to pass through a heated coil, then to escape into the room. In a very short time the air can be brought to any desired warmth, and with this great advantage, that the warm air passing into the room may be dried and filtered on its way by interposing within the tube which feeds from the outer air or from the escape tube a screen of dry cotton wool, or any other surface that will absorb moisture. By this stove the air of the room can also be rapidly warmed to any desired point. I have often had one of these stoves introduced into the sick room, and I never had occasion to regret the practice.

Therapeutical Notes.

In one of the cases related above an astringent mixture was prescribed with good effect. This course is very sound in the class of cases named, and I know of nothing that need stand in its way. We must always remember that hydrops bronchialis is a condition so fatal that when it is present there is no hope until it is removed. As well try to save the life of a drowning man while he is under water as try to save a man drowning in his own secretions by any means that have not for their primary object the liberation of the lungs from the embarrassment in which they are placed. For additional aid to the external measures, the use of an astringent mixture of diluted sulphuric acid is as rational a plan as is the use of the same mixture for the treatment of hæmorrhage or diarrhœa. Neither is there any astringent in the whole list of remedies that acts more directly as an astringent on the bronchial mucous surface. To the acid mixture opium may be added if sleep is an urgent necessity, for there is no danger in giving gentle repose under an opiate which exerts, on its own part, good astringent properties. A ten minim dose of the diluted acid solution in a half ounce of water may be administered every hour, five minims of Battley's solution of opium being added according to requirements from time to time.

It is customary in cases of the kind under consideration to place hot bottles, or heated bricks, to the feet and limbs. The practice is a good one, and may be followed more freely than is usual. It is wise to place the heated bottles, wrapped in flannel, under the arms as well as by the limbs; it is also useful to extend the ends of the flannel from the heated bottles over the body of the patient, and to keep careful watch that the warmth is steadily sustained by frequent renewal of the warming appliances.

These are the best measures as yet known for the treatment of hydrops bronchialis; they are necessarily slow in their action, and I doubt not the day will come when science will show the way to a very much quicker method. In hospital the use of a hot air bath would be, without any demur, a remedy eminently ready and scientific, perhaps the very best remedy that could be devised. For these advancements, simple as they are, we must submit to wait, doing our best, meanwhile, to acquire the correct knowledge of principles, to act on that knowledge as well as we can, and to push on the development of details to their most advanced perfection.

A Fatal Epidemic of Measles.

The inhabitants of Kamtchatka have been visited by an epidemic of measles which, as is often the case in people normally free from the disease, proved extremely fatal. The number of victims is roughly estimated at ten thousand. When, however, we are told that a whole village of 800 inhabitants was completely wiped out by the disease we cannot help suspecting that the telegraph operator is imposing on our credulity.

Clinical Records.

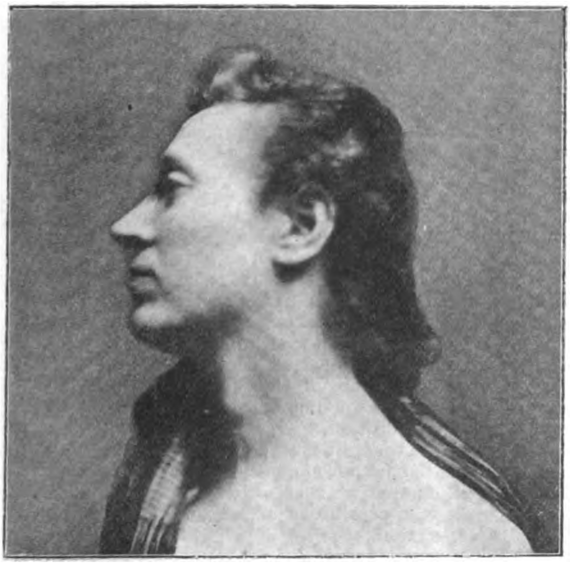
ROYAL FREE HOSPITAL.

A Case of Branchial Cyst.

Under the care of **James Berry**, F.R.C.S.,
Surgeon to the Hospital.

S. C., a married woman, æt. 41, the mother of six children, was suffering from a swelling on the left side of the neck. She stated that at birth there was a little hole about the size of a pin's head in the lower part of the left side of the neck, which never discharged or troubled her in any way until she was about sixteen years of age. She then noticed that a viscid yellow fluid, with an unpleasant taste, occasionally—*i.e.*, about once a week—came into her mouth. At about twenty years of age the escape of fluid into the mouth ceased, but the hole in the neck then began to discharge a viscid yellow fluid similar to the other.

A swelling then formed near the hole about the size of a nut, in which she felt a pricking pain. She said she could feel a cord passing from the hole upwards and inwards to the mouth, which, when squeezed from above downwards caused the secretion to escape from the hole in the neck.



The swelling was at first treated by poulticing under medical advice, but it was not until she was twenty-four years of age that it finally ruptured and disappeared.

It subsequently reappeared, and when it had attained the size of a walnut, she went to University College Hospital, where it was incised and the fluid evacuated. This was done on three occasions without effecting a permanent cure. When twenty-nine years of age the opening was dilated, but it closed two months later. When thirty-seven years of age the swelling recurred, and when about the size of a chestnut it was excised, the wound was drained and healed. The patient describes the lump after it had been removed as being like a bag containing yellowish fluid.

About six months ago she noticed a lump about the size of a pea higher up in the neck, which was gradually increasing in size. She complained of some difficulty in swallowing, but no fluid taken into the mouth had ever escaped through the external opening. She has two sisters with similar holes on the right side of the neck, associated in one with a discharge. A maternal grandmother also had a hole in the left side of her neck. Not one of the patient's six children presented any lesion of the kind.

On admission there was a swelling on the left side of the neck in the middle third about the size of a walnut, lying internally to the anterior border of the sterno-mastoid, the most prominent part being on a level with the thyro-cricoid membrane. The swelling reached to the upper border of the thyroid cartilage, a process passing deeply behind the great corner of the hyoid bone in the direction of the pharynx. A small lump about the size of a pea lay below the larger swelling, near a depressed scar.

The tumours were situated beneath the superficial fascia, they were elastic and fluctuating, obviously containing fluid. They had a well-defined outline and were not particularly tender. They were freely movable from side to side, but not from above downwards, and they moved on swallowing.

There was a scar about 1¼ inch in length, beginning about half an inch from the inner end of the left clavicle and passing upwards and outwards to the anterior border of the sterno-mastoid muscle. At the upper end of the scar there was a slight depression. The diagnosis was in favour of the swelling being of the nature of a branchial cyst.

On October 20th, 1902, the patient was anæsthetised, and the head was fixed in an extended position with the face turned toward to the right side. An incision was then made on the left side of the neck, beginning about half an inch from the left angle of the jaw and extending downwards and inwards for 5¼ inches, ending about half an inch from the left sterno-clavicular articulation and passing through the old scar.

The skin and platysma were divided, and all bleeding points clamped. The cysts were then exposed, being bound down by connective tissue to the infra-hyoid muscles. The connective tissue was dissected away over the upper part of the swelling, across which a branch of the external jugular vein passed. This was ligatured in two places and divided. The cysts were then lifted out of the wound and freed as far as possible. The upper part passed deeply between the external and internal carotids, and beneath the digastric tendon and superior laryngeal nerve, the common fascial vein passing underneath it.

A probe was passed into the lower end of the swelling and some brownish fluid escaped. When it was passed as far as it would go the point could be felt with the finger in the mouth just behind the tonsil. Gentle traction was exercised on the cyst in order to ligature it as high up as possible, but this caused it to rupture. On closer examination of the parts, the upper end was found to be closed, and proceeding from it was a thin white cord about an inch in length.

The wound was swabbed out with sterilised gauze steeped in a solution of 1 in 2,000 hyd. perchlor. A drainage tube was inserted into the upper end. The skin was then united by a continuous fishing gut suture, and a stitch was put into the tube to keep it in position.

The wound was dressed with sterilised gauze. Saline sponges were used throughout the operation, except at the beginning and end, when sponges steeped in sublimate solution were employed.

The specimen removed consisted of a sort of bag dilated at the lower end to about the size of a pigeon's egg; immediately above this was another dilatation the size of a hazel nut. The part of the specimen above the dilatation was about the dimensions of a lead pencil. Attached to it was a tag about the thickness of fine string an inch in length. On pricking the cysts a brownish fluid escaped, consisting apparently of altered blood and mucoid material.

The specimen measured five inches in length. On the day following the operation (October 21st), patient was fed per rectum every eight hours, the enemata consisting of beef-tea two ounces and milk two ounces. Nothing was given by the mouth.

The temperature was 98° and pulse 80 She had also saline injections of one pint every eight hours.

The drain was removed. Four days after the operation she had four tablespoonfuls of water by the mouth. She experienced no difficulty in swallowing. The stitches were taken out.

On October 26th, six days after the operation, she was puton solid diet.

The wound has completely healed up, but there remains a slight amount of swelling in the upper part of the scar.

Transactions of Societies.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held Thursday, October 23rd, 1902.

The President, Rushton Parker, B.S., F.R.C.S, in the Chair.

CASE OF INTESTINAL OBSTRUCTION BY A GALL-STONE.

Mr. Newbolt read a case of intestinal obstruction caused by the impaction of a large gall-stone in the small intestine. Laparotomy and removal of the stone by incision of the gut was followed by recovery. The patient was a stout woman, æt. 54. The stone, when dry, weighed 308 grains, and was two inches in length.

Mr. F. T. Paul had seen a similar case. He drew attention to a less serious form of obstruction, due to paresis of the bowel, caused by local peritonitis, secondary to cholecystitis.

Dr. Bushby and the President commented upon the case, and Mr. Newbolt replied.

CASE OF MALARIA.

Dr. Macalister related the case of a young American sailor suffering from a first attack of malaria, which he had acquired on the West Coast of Africa. Treatment was rendered difficult owing to the inability of the patient to take quinine, which either caused vomiting or if absorbed led to a distressing train of symptoms. In from half to three hours after taking a dose he became covered with a scarlet rash, and accompanying this there were severe frontal headache and vomiting; pain in the eyes, which were congested and watery looking, and the eyelids swollen. There was also buzzing in the ears. These symptoms, which were associated with sensations of great prostration and weakness, generally passed off in about seven hours. The smallest dose of quinine or of any preparation containing the cinchona alkaloids, resulted in the same train of symptoms, and neither the time of their administration in relation to the malarious exacerbation nor their combination with other drugs, served to establish a tolerance.

CASE OF ATTEMPTED SUICIDE.

A second case related by Dr. Macalister was one of attempted suicide. The patient being an elderly man, who swallowed a teaspoonful of what he thought to be crude carbolic acid. It was a non-corrosive disinfectant, having an odour resembling creolin, and the symptoms which it produced were abdominal pain, congestion with some cyanosis of the face, drowsiness and mental hebetude. He had considerable difficulty in understanding what was said to him. Heart and lungs normal, pulse 90, regular but small. Respirations, 24. On the day following his admission it was noted that his complexion was dark and of an olive-green tinge. The breath had a creolin-like odour; his drowsiness continued in a lesser degree. No blood was evacuated either from the stomach or bowels. The urine was very dark in colour (like porter); it contained no albumin; sp. gr. 1029. The elimination of this foreign substance took place through the kidneys, and the urine, after remaining very dark for three days, gradually became lighter and lighter in colour, the specific gravity falling with the diminished colouration. It was always acid, never contained albumin, and never seemed to have any irritative action on the renal epithelium. The interest of the case depended on the fact that the man's blood was drenched with an antiseptic which took six days to become entirely eliminated, and the urine which he passed has remained undecomposed and perfectly free from micro-organisms, although it has been lightly covered in a wide-mouthed bottle for thirteen months. Dr. Macalister suggested that there are some diseases in which we would like to saturate the blood with an antiseptic in this way, and if he could be certain of the nature of the substance which this man took with the purpose of doing himself a grievous harm, he would feel very much inclined to administer it in considerable doses. Unfortunately the patient had carefully washed out the vessel which had contained the poison, which had been lying unlabelled in his possession for a long time, and it was impossible to obtain any certain evidence concerning its nature.

Dr. Burns Gemmel emphasised the value of the exhibition of opium in cases of quinine intolerance, and reminded members of the use of opium preparatory to the administration of ipecacuanha. Small doses of opium were useless, the patient must be well under its influence.

Drs. Lloyd Roberts, Murray Cairns, Craigmile, and H. Armstrong spoke and Dr. Macalister replied.

REPEATED CÆSAREAN SECTION.

Dr. Arthur Wallace read a note based on a case of the successful performance of conservative Cæsarean section twice on the same woman. The abdominal cicatrix was intact, and there was no trace of intra-peritoneal adhesion. The uterine scar was visible as a faint linear depression, and the uterine wall when incised in this site measured 15 mm. in thickness. In view of the recent publication of cases in which extensive utero-parietal adhesion had allowed repeated sections to be performed extraperitoneally, Dr. Wallace considered that some attempt should be made to bring about utero-parietal adhesion sufficient to obtain this advantage. Therefore, after closing the uterine wound, an extensive ventrofixation was carried out, an area of the uterus measuring three inches by one inch, corresponding to the extent of the wound, was sutured to the lower part of the parietal opening. For two months afterwards the uterus remained in its elevated position, and then gradually descended to the usual level of the pelvis.

Dr. Burton had acted upon Dr. Wallace's suggested plan in a recent Cæsarean section that he had performed. He hoped, therefore, in the next operation, when required, that he would be able to carry it out without opening up the general peritoneum.

Dr. Grimsdale pointed out that although the incision in the uterus at the time of the section was about five inches, the scar was only about one inch long when involution of the uterus was complete. In a second pregnancy the muscular tissue would grow but not the scar, and therefore if the whole length of the scar was adherent, he did not think it would in any way help a future operation.

Dr. E. T. Davies thought it was improbable that any adhesions would persist permanently in an aseptic operation. The real chance for success in Cæsarean section depended upon the possibility of securing a suitable time for the operation.

Dr. J. E. Gemmell felt that in favourable cases, *i.e.*, those with known pelvic deformity, and time of operation chosen, the results were almost as satisfactory as uncomplicated ovariotomy. Unless a well-marked inflammatory process produced the adhesions, he did not think they would be of much service in a second section.

Dr. Briggs also spoke, and Dr. Wallace replied.

Mr. Thelwall Thomas read a paper on

AN OPERATION FOR UMBILICAL HERNIA.

He utilised the transverse incision, and always excised the greater part of the skin covering the hernia. The neck of the sac was now freed, and the sac explored through an incision near the exit from the abdomen. Omentum was at once tied off, and the stump returned into the belly, a free cutting up of the hernia was now easy and bloodless. The gut was now dealt with, and the sac containing the adherent omentum cut off. The stump of the sac was clamped in a transverse direction and closed by continuous silk suture, leaving at each end a length of silk. A place was prepared for it in the extra-peritoneal tissue above the aperture in the linea alba, into which it was drawn by threading the silk ends through the abdominal aponeurosis, and suturing them finally into the aponeurosis. The aperture in the linea alba was drawn taut in a transverse direction by strong tractors, the margins notched freely with scissors, and held together by mattress sutures, so that the suture line was transverse. The skin wound was closed transversely, and a small glass drainage tube passed through an independent puncture. He had performed the operation in nineteen cases, some of large size, with recurrence as yet in one only, and in this the silk had been infected during operation, and suppuration set in.

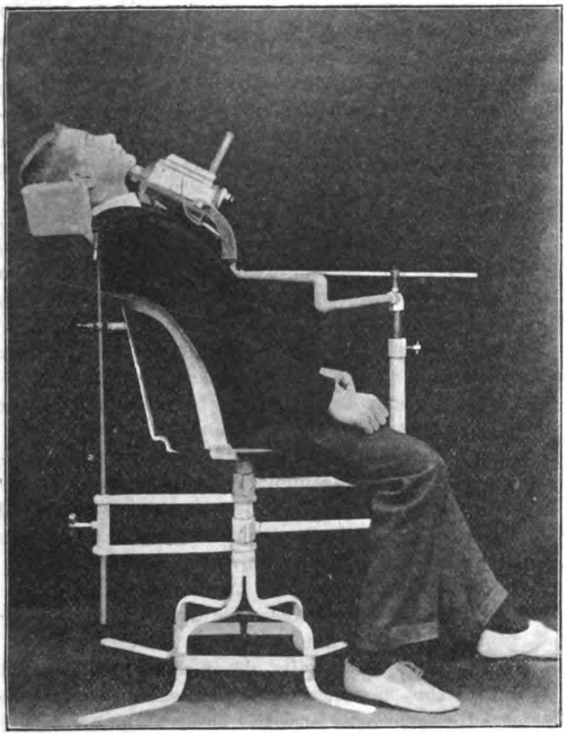
The **President** considered umbilical hernia the most difficult of all hernia on which to perform a radical cure. He thought the transverse incision much the best operation in general.

Mr. **F. T. Paul** had adopted the operation recommended by Mr. Thomas, and thought highly of it.

Drs. E. T. Davies and Briggs and Mr. R. W. Murray spoke, and Mr. **Thomas** replied.

NEW FINSEN LAMP.

Dr. **Stopford Taylor** showed a new lamp designed to meet the demand for a very small lamp, automatic in its action, burning iron or carbon electrodes and working direct from the electric supply main.



This photo shows the lamp applied under the chin. This is one of the most difficult positions to reach, but the illustration shows that it can be easily treated with this lamp.

These conditions are fulfilled by making the shell of the lamp a water-jacket of very small proportions, mounted on a frame which permits motion in all directions, and at the same time is rigid when in working position. It is imperative that the diseased area to which the lamp is applied be rendered anæmic, so that the rays can penetrate the tissues mere application of the lamp being futile unless sufficient pressure be exercised to produce this effect. For this purpose he obtained the chair from Berlin, and had the lamp attached to it by means of a powerful bracket, steady pressure of the lens against the patient being maintained by a rack and pinion adjustment and counter pressure by the headrest. Fifteen to twenty minutes is sufficient to produce a good reaction. It is noiseless, and on the score of economy it is a distinct advance on all modifications of Finsen's apparatus. The current is two amperes at a pressure of forty volts across the arc. The rubber water tube connections have been removed so as not to obscure the lamp. Dr. Taylor said he was indebted to Messrs. John Hunter and Co., of Liverpool, for their skill in carrying out his suggestions.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Meeting held at Liverpool, October 17th, 1902.

Dr. S. Buckley, President, in the Chair.

Dr. **Archibald Donald** (Manchester) related a case of *Kraurosis vulvæ*. The patient was a single woman, æt. 62, who had ceased to menstruate seventeen years before. The symptoms which had existed two years had been at first severe pruritus vulvæ followed by pain at the vaginal orifice. Micturition was increased in frequency and there had been slight loss of flesh for three or four months. The patient stated that she had had "diabetes," but careful examination of the urine failed to detect any sugar. Examination of the vulva revealed a raised hard flattened swelling, slightly ulcerated on the surface, situated on the inner surface of the right labium and extending slightly into the vagina. There was extreme atrophy of the skin and mucous membrane. The external genitals had so shrunk that the vagina would not admit the little finger. The skin was pearly white, and tore readily. The uterus and vagina were found to be double, the septum extending to the hymen, which was intact. The whole of both labia, including the nodule, were excised. Dr. Donald remarked on the rarity of the disease and its diagnosis from senile atrophy and pruritus vulvæ. It also seemed to have some relation to malignant disease. Microscopical sections were shown.

Dr. J. E. Gemmell, Dr. H. Briggs, and others remarked on the evidence of epithelial proliferation in some of the sections which would suggest the possibility of malignant new growth rather than an atrophic disease.

Mr. **Damer Harrison** remarked that epithelial proliferation was not uncommonly present in the neighbourhood of atrophic diseases elsewhere; for instance, in perforative ulcer of the foot.

Sudden Death after Confinement.—Dr. **Nathan Raw** (Liverpool) narrated the case of a woman who died suddenly two days after confinement. The labour was natural and the patient was apparently quite well, when, without the slightest warning, and whilst her husband was talking to her, she suddenly expired. Postmortem the pericardium was found distended with blood clot, resulting from the rupture of a large aneurysm of the aorta into the pericardial sac. The disease had not been suspected during life. The specimen was exhibited.

Dr. **Murray Cairns** (Liverpool) showed a fœtus with extreme hydrocephalus associated with spina bifida. Delivery had been effected after perforation of the after coming head. He suggested that possibly under such circumstances a free incision into the spinal sac would have allowed a more gradual escape of the fluid and a less sudden diminution of pressure in an over-distended uterus.

Ruptured Tubal Gestation.—Dr. **Arnold W. W. Lea** (Manchester) showed a ruptured pregnant Fallopian tube and ovary removed during the stage of active bleeding. The patient consulted Dr. Lea on account of her having missed two periods and having had slight continuous bleeding for two weeks, followed by a sharp hæmorrhage and passage of a "piece of flesh" one week before seen. Recurrent attacks of pain had also been present. On examination a rounded swelling was found on the left side of the uterus, and the latter was displaced to the right. The swelling was mobile. Tubal gestation was diagnosed and arrangements made for admission to a nursing home next day. The same evening, however, severe pain and symptoms of internal hæmorrhage developed. Morphia was given and the symptoms being relieved operation was not performed until next morning, when the abdomen was opened. There was much fluid blood in the peritoneum, and actual bleeding was found to be taking place from the ruptured sac of a left Fallopian tubal pregnancy. The tube and sac, together with the ovary, were removed. The sac was about one and half inches long and three quarters of an inch in thickness, and was ruptured at its centre. It was situated one and a quarter inches from the uterine end of the tube. The fimbriated orifice was not closed, but no bleeding had apparently taken place from it. The patient has made a good recovery.

Carcinoma of the Body of the Uterus.—Dr. W. **Walter** (Manchester) showed a uterus removed by vaginal hysterectomy from a nulliparous woman, æt. 62. She had passed the menopause ten years. The uterus was enlarged, but the cervix was normal. Slight loss of flesh and occasional metrorrhagia were the only symptoms. The vagina being narrow from senile changes, division of the uterus was necessary before hysterectomy was possible. The whole of the fundus and body of the uterus was extensively diseased, the microscopical sections showing the appearance of adenocarcinoma. It is unusual in so advanced a case of cancer of the body of the uterus as this, to note an entire absence of pain.

The specimen was discussed by Drs. H. Briggs, Arnold Lea, Lloyd Roberts, and J. E. Gemmell, and Dr. **Walter** replied.

Dr. E. O. **Croft** (Leeds) showed a specimen of *Bilateral papillomatous ovarian cysts*, removed from a 7-para, æt. 44. The tumours presented the naked eye characters of ordinary multilocular cysts with the presence of a few scattered warty growths on their surfaces and within some of the cysts. There were also a few minute papillomata on the posterior surface of the uterus. The tumours were about the size of an infant's head, and a closed fist respectively. A nodule of growth was also found in the omentum, which was freely removed. Microscopically the appearances were those of columnar-celled carcinoma. The fact that with such advanced disease of both ovaries, the patient should have passed through a normal labour only two years before, and after suckling the child that menstruation had recurred naturally until the time of operation was remarkable. The patient had suffered from pain and had noticed a lump in the body about nine months before.

Dr. **Lloyd Roberts** (Manchester) showed the fœtuses from a *case of Quadruplets*. The patient, æt. 27, was delivered at the sixth month of her fourth pregnancy. The previous pregnancies were single births. The labour lasted twenty-four hours. The fœtuses were born at intervals of fifteen minutes, three of them having been alive at birth. The presentations were two vertical and two pelvic. There was much liquor amnii and some post-partum hæmorrhage. The placenta was single, four distinct amniotic sacs being enclosed in a single chorion. The patient made a good recovery and is now pregnant again.

Germany.

[FROM OUR OWN CORRESPONDENT.]

Berlin, November 1st, 1902.

At the Society for Innere Medizin Hr. v. Leyden related a case of

Paralysis of the Lower Extremities from Lightning.

The external clothing of the injured man was intact, but the shirt was completely carbonised, and on the skin over a full third of the whole superficies of the body were burns, in very varying degree from the slightest to the most extreme. In various parts of the body there was stellate burns. The head was quite uninjured. It was suspected that the lightning had struck the metal buttons of the shirt, and had passed thence to the right trouser-pocket, where the purse was, as the burning was most severe on that side. The speaker observed that the restaurant on the summit of Piz Languard where the accident took place, had been twice struck by lightning during the previous year. A lightning rod had been provided, but it appeared to be a doubtful protection from lightning.

At the meeting of Physicians and Scientists, Hr. Monti discussed

Serum Exanthems.

He said it was certain that diphtheria antitoxin was harmless, and that it could not be looked upon as the cause of serum exanthems. The former suspicion also, that serum exanthems were caused by streptococci, or by the small quantity of phenol of the serum was unfounded. It was most probable that the explanation given by Oertel was the correct one, viz., that such exanthems were the result of an injection of an albuminous fluid of a different species of animal and causing intoxication in the blood. This view had been confirmed by the experiments of Johannespen and himself. He described his own experiments and the clinical appearances that followed. The quantity of the serum injected appeared to be of importance. The larger the volume of the serum injected the more frequent was the following exanthem. Since serum of higher therapeutic power had been employed, whereby the volume of the serum injected had been diminished, these serum exanthems had become less harmful and less frequent. Such exanthems now appeared in only 3 per cent. of his cases. In order to avoid them as much as possible, however, the following rules should be observed:—

1. Only serum that is perfectly clear should be used.
2. If the serum be cloudy it should be warmed before use to 35° C., and it should only be used when after repeated warming the turbidity has completely disappeared.
3. The same applied to serums that had been kept for some time and show a white flocculent deposit.
4. High potency serum should be selected, so that it be not necessary to inject more than 10 ccm.
5. As a precautionary measure it would be well to recommend repeated warmings of the serum up to 35-5° C. This can be done without lessening its activity, and when larger volumes were required, by this means the cocci development of exanthem will be best destroyed.

Hr. Ledermann spoke on

The Bactericide Preparations of Various Yeast Preparations.

He spoke of the results obtained by Landau and Albert in the treatment of vaginal disease by active yeast. He mentioned also the observation of Albert that sterile yeast still possessed this property. After Lassar, Brocq and other dermatologists had recommended the internal use of yeast in the most varied dermatoses, the speaker, in company with Hr. Klopstock, had sought to confirm the bactericidal action of yeast by animal experiment in the Institut for Medical Diagnosis, without being able to come to any definite conclusion, however, as they had not been able to set up the skin diseases required in the animals experimented on. They could only show the harmlessness of feeding rabbits with compressed yeast. They had to fall back therefore on reagent experiments *in vitro*, and endeavour to determine the action of the various kinds of yeast recommended for use in skin diseases upon bacteria, in which grape sugar, peptone, and bouillon were inoculated alternately with typhoid bacilli, with staphylococci, or the colon bacilli. After various periods of fermentation the following results were obtained:—

1. Typhoid bacilli were killed by fermenting yeast in twenty-four to forty-eight hours, by compressed yeast after twenty-eight hours, by levulose after seventy-four

hours; while furunculin and a yeast cell pure cultivation did not affect the growth.

2. Staphylococci were killed in the same way after forty-eight to fifty-four hours, by compressed yeast after twenty-four to fifty-four hours, by levulose after seventy-four hours.

3. Colon bacilli were killed after seventy-two to seventy-six hours, by compressed yeast after twenty-four hours, by levulose after seventy-four hours. Furunculin and yeast cells in pure cultivation had no influence on the growth of staphylococci and colon bacilli. Rapp had recently arrived at similar conclusions, so that the bactericide action of the yeast preparations said to be active appeared to be certain.

In conclusion, it was recommended that when yeast was given internally the food should be as amylaceous as possible.

In the department for Forensic Medicine, Hr. Kratter Gratz spoke on

The Determination of Animal and Human Blood.

Several investigators had found that blood serum of rabbits which had been injected for a lengthened period with blood of another kind of animal or man, acquired the property of setting up precipitation only in solution containing the blood of the animal with which they had been previously treated. On this had been based a method of distinguishing human from animal blood forensically. The speaker had tested the method as to its practical value, and he uttered a warning against its present introduction into forensic cases, as in the hands of only moderately skilful people errors having very serious consequences might occur.

Austria.

[From our own Correspondent.]

Vienna, November 1st, 1902.

Ephemeral Glycosuria following Injuries.

At the "Naturförscher" Borchard brought before the meeting several observations of injury to the head followed by the temporary appearance of sugar in the urine.

The first patient had 1·5 per cent. of sugar and 1·2 of albumen, which disappeared twelve hours later; but after another pause of twelve hours blood corpuscles and casts appeared in the urine.

In another case, after a similar injury to the head, the same conditions appeared, but the patient unfortunately died. The post-mortem examination revealed nothing in the fourth ventricle or cerebrum, but there was a cloudy condition of the uriniferous tubes and glomeruli. Borchard attributes the temporary glycosuria and albuminuria to a disturbance of the circulation of the kidneys, and not to any injury to the brain; neither is it due to the ordinary morbid conditions that bring about the persistent condition; nor can we attribute it to alimentary glycosuria, since no foods likely to cause it were given in either case.

In the discussion that followed Stolper said that he had met with glycosuria after similar accidents to the spinal column.

Neugebauer remarked that Stolper's cases of analgesia in females required closer scrutiny before he could accept them as relevant. These cases of sacral segments are always fraught with a certain amount of suspicion, and this was true in respect of both the conus and root affections.

Pulmonary Anæsthetisation.

Kuhn raised the question of pulmonary anæsthetisation direct. He thought we had waited and searched a long time for an anæsthetic centre in the nervous system without much hope of immediate success.

Trendelenberg's observations that anæsthesia was easily obtained when applied direct to the wound in tracheotomy seems of such importance that such operations might be performed with advantage by applying the narcotising agent direct to the lung. This method of administering the drug is more rapid and efficient, with less danger of over dosing, than when exhibited in the usual way. Spasm of the glottis or asphyxia by mucous membrane is unknown, as well as the subsequent vomiting and retching which often follows recovery from large doses of the drug. In reply to Eiselberg he said he had narcotised in this way in fifty cases.

Landerer thought this form of treatment would be unsuccessful in an alcoholic subject.

Kuhn replied that the patient must commence with brom-ethyl, giving the chloroform later.

Eiselberg thought that intubation would not be so easily done under the narcotic. Fink desired to see an example before he would pass judgment.

Wohlgemuth doubted if any narcotic could be relied upon not to produce vomiting. During the last few years he had devoted a good deal of personal attention to the subject even to oxygen and chloroform, but was unsuccessful. Neither the anæsthetic nor the mode of administration have any effect in checking it; some individuals with a minimum dose suffered from sickness, while others with a large dose escaped.

Medullary Anæsthesia.

Neugebauer related experiments with sterilised tropacocain to a dangerous degree of intoxication, and he had arrived at the conclusion that it was only useful in cases of operations on the legs, where general anæsthesia was not so well borne.

Preindlsberger said he had performed thirty operations with this drug under deep intoxication with the best results. In females the analgesia was perfect. The injections are best borne on the upper part of the pelvis.

Treatment of Tuberculosis.

Landerer related his success in emphysema and tuberculous abscesses in the lung, which he treated by section.

The opening of the chest in tuberculous cases was not a danger if carefully done in cases other than the miliary form. Stationary cases always gave the best results. Tubercule caverns of the lower lobe should always be treated by section He drew attention to the care necessary in healing, which was often spoiled by the cicatrix. In coxitis rapid healing of the wound often produced such contraction as to determine spontaneous dislocation of the epiphysis.

Hofmeister related a strange case of non-tuberculous cavity in the lung that he resolved to operate on, which healed up and left a cavity. On re-opening the cicatrix the cavity disappeared.

Boschard thought we had far too few cases to establish a principle upon. Quincke showed some time ago that the healing of cavities was hardly possible.

HYPERTROPHIED MAMMÆ.

Wirshaupt showed photographs of hypertrophied mammæ associated with pregnancy which he removed, each weighing 6,700 grammes, or 14·74 pounds.

HARE-LIP—A WOLF PALATE.

Springer reported the result of fifty-three cases in the "Josef Kinderspital." They do not operate during the first year for cases where the gum is split, to avoid enteritis, nor before six months of age, while the lip alone is cleft. In thirty-one cases operated on no death occurred, although eight of them refused to heal. It is rather peculiar that the functional results are not always parallel with the anatomical repair, as children with imperfectly healed lips often articulate better than the ideal result as far as the operation is concerned.

Hacker was in favour of Schleicher's infiltration method.

Bringer recommended Kuster's operation with the two flaps, and believed better results were to be obtained from it.

Riedel was in favour of keeping the head hanging down while operating as it obviated pneumonia.

Eiselberg praised Kuster's method, as it gave both better function and anatomical results.

The Operating Theatres.

ROYAL FREE HOSPITAL.

INTESTINAL ANASTOMOSIS FOR FÆCAL FISTULA COMMENCING WITH TUBERCULOUS CÆCUM.—MR. ROUGHTON operated on a man, æt. 35, who a year previously had presented himself at the hospital suffering from vomiting, and a lump on the right side of the abdomen. An exploratory operation was at that time performed, and a mass of tuberculous disease was found to involve the cæcum. A small piece of tissue was removed for microscopic examination, and the diagnosis confirmed. Three days after the operation there was discharge of fæcal matter from the wound. At that time the man's general health was extremely bad; he, however, had steadily improved after his discharge from the hospital, and was at the time of the present operation in fairly good general health, but his fæcal fistula still remained and was a source of such serious inconvenience that he was compelled to seek further aid. On exposing the abdomen a fistulous opening was seen in the middle of a scar situated in the right iliac region, the skin in the immediate neighbourhood being much inflamed and obviously very septic. Before proceeding to operate, Mr. Roughton thoroughly occluded the fistula and the surrounding septic area with gauze and collodion. He then made an incision about four inches long about an inch to the right of the middle line. On exposing the rectus muscle this structure was drawn outwards, but not incised; the posterior sheath of the muscle and the peritoneum were opened opposite the superficial incision. The lowest part of the ileum was found to be much thickened and dilated, and studded with tubercles; its mesentery was nearly half an inch thick, and of tough leathery consistence; on tracing it towards the situation of the fistula it was found to enter a dense mass of tuberculous disease occupying the situation of the cæcum and of the ascending colon. The transverse colon, which was very thin and empty, was then brought down into the wound and clamped with rubber tubing passed through the mesentery. A portion of the distended ileum free from tuberculous disease was then clamped with Doyen's forceps, and an anastomosis between the two portions of bowel effected by a double row of sutures without the aid of any mechanical contrivance. The peritoneum and the posterior sheath of the rectus were sewn up by a continuous silk suture, the rectus muscle was slid back into place; the anterior sheath and skin were next similarly united and the usual dressings applied. Mr. Roughton said that it was remarkable that this patient had so greatly improved in general health during the year that had elapsed since the first operation, although the tuberculous disease had remained *in statu quo*. It was, he remarked, a common experience for tuberculous disease of the peritoneum to disappear after abdominal section, but in this case the disease remained, although the general health improved. He pointed out that the very septic condition of the fistula and of its neighbourhood had induced him to make his incision at some little distance from the seat of disease, as he feared that any operative procedure undertaken *in situ* would have been attended by enormous risks. He said that the method of opening the abdomen he had adopted in this case was attended with less risk of subsequent ventral hernia than when the linea alba was incised, because the injured rectus muscle intervened between the two layers of incised and sutured tissues. He thought the advantage of this method over a similar proceeding which is sometimes employed at the outer margin of the rectus was that the nerve supply of the muscle is not interfered with or damaged. He considered that the dilated and hypertrophied condition of the small intestine afforded ample evidence that the passage of fæces through the diseased cæcum was considerably obstructed. It was, he remarked, a well recognised principle in surgery that a fistulous opening will not close so long as the normal passage with which it communicates is obstructed, therefore the first requirement in this case was to afford a free passage for the onward flow of fæces; this was the object with which the operation of anastomosis was performed. Mr. Roughton said that if all went well it was quite possible that the fistula might close without any further operation, yet it might perhaps be necessary at some future period to attack the fistula itself.

It is satisfactory to state that the patient made an uninterrupted recovery from the operation, and that six weeks afterwards when he left the hospital, although the fistula had not completely closed, there was no escape of fæces from it, nor had there been any since the operation.

A Fatal Dispensing Error.

AN inquest was held last week on a child, who succumbed to the effects of a poisonous dose of strychnine inadvertently dispensed by Mr. H. Laird Pearson, of Birkenhead. Mr. Pearson was so confident of his innocence of error that he actually swallowed a dose himself with serious results. Another child of the family who was given some medicine from the same bottle also suffered severely, but was saved by prompt treatment. The parents of the children publicly expressed their sympathy with the doctor in his trying position, an act which reflects great credit upon them.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 5, 1902.

THE BERLIN CONGRESS ON TUBERCULOSIS.

THE principal result of the Congress on Tuberculosis, which has just taken place at Berlin, is to give prominence to the problems which still await solution. Until these points have been cleared up no practical conclusions are possible, and to attain this end many years of patient observation and investigation will be required. The discovery of the bacillus of tuberculosis marked, it is true, an epoch in the history of the disease, but although we have learned to recognise the enemy against which we have to fight, we are still in great measure without arms wherewith to conduct the campaign. We have yet to determine which of the two etiological factors, the bacillus or the soil, is the more important, whether our efforts should aim at the destruction of the *materies morbi* or whether we ought to concentrate our energies on the soil with the object of rendering it capable of resisting the invasion. In Germany the bacillus is generally accorded the foremost place, but elsewhere, judging from the measures adopted, most importance is attached to reinforcing the resistance of the tissues. Intimately connected with this question is that of the identity of bovine and human tuberculosis, and no stringent prophylactic measures can be hoped for until this much-debated question has been settled. Of the transmissibility of the disease from man to man no serious difference of opinion obtains, so that one prophylactic indication, at any rate, is available for instant use. In his endeavour to controvert Professor Koch's conclusions, M. Nocard, of Alfort, did what lay in him to introduce fresh elements of uncertainty into the discussion by stating that there is not one specific agent in tuberculosis but several, and that while cattle are refractory to certain of the micro-organisms associated with the disease they are perfectly susceptible to others. That the bacilli met with in this connection vary greatly in virulence is no doubt true, but that fact does not justify their being described as of various species. The arguments re-advanced by Professor Koch are not more convincing now than they were when first enunciated at the London Congress. He declines to admit that the prevalence of intestinal—or shall we say abdominal?—tuberculosis in infants is evidence of alimentary infection, on the ground that indubitable instances of primary intestinal lesions are extremely rare. His objection, however, reposes on the assumption that infection by the mouth necessarily manifests itself by infection of the intestinal structures, but to assume this is to beg the question, indeed, there are a number of experimental data on record which go to prove that the bacillus, intentionally introduced into the alimentary canal, often works out its destiny in the lungs rather than in the intestinal structures. Since the bacillus, however introduced, selects, at one time the mesenteric glands, at others the lungs and, less frequently, attacks the synovial membranes of joints, the meninges, the vesical mucosa, &c., it is difficult to avoid the conclusion that it is the nature of the soil rather than the action of the specific agent which determines the susceptibility. The general impression left by the discussions is that the principal danger, if indeed, not the only one, lies in the undue susceptibility of the tissues to adverse influences. Just as cholera and plague have been stamped out of England by a stricter application of the laws of hygiene, which have conferred a measure of protection almost amounting to immunity, so the application of the laws of hygiene, aimed at the improvement of the social conditions which prepare the soil for tuberculosis, may, in the long run, render the race refractory to the microbe of this disease. This conclusion is absolutely in accordance with all that we know concerning the spread of infective maladies. Without declaring impossible the discovery of an immunising serum, the introduction of sanitary measures tending to assure a standard of health incompatible with infection would unquestionably be far more beneficial to the community.

PREVENTION OF ENTERIC IN ARMIES.

DR. LEIGH CANNEY has again brought his views on the prevention of typhoid before the medical profession, on this occasion at a meeting of the Medical Society of London. Dr. Canney's views are by this time well known, and we have already directed attention to them in our columns. Reform the water supply of armies, he says, and all other sources of enteric infection may be neglected. It is difficult to accept this dogma in its entirety, especially in view of certain recent epidemics, and the aerial convection of infection on particles of dust must be given its place. Colonel Davis, R.A.M.C., when discussing Dr. Canney's paper, drew attention to an epidemic at Quetta, where, although the entire drinking water was supplied from an un-contaminated source, there was an outbreak of typhoid. The origin of this outbreak was found in a series of shallow trenches which received typhoid dejecta, and which were situated in the eye of the prevailing wind; and this was clearly proved by the fact that the battalion which was nearer the trenches and more in the direct line of the wind suffered out of all proportion to the other battalions. As we understand Dr. Canney, his point is that but for a preliminary inoculation of the army by water-borne infection there would be no infected dust to repropagate the infection. This may be so, but how did the water become infected? To be strictly logical Dr. Canney should also decry the importance of water-borne infection as soon as the original source of the water infection was discovered. The course of events appears to be that the prime source of infection infects the water, the water infects the army, the army infects the soil, and the dust from the soil reinfects the army and the water. If one could remove the original source of infection before it produced its effect then all the secondary sources of infection might be neglected; but when once a secondary source of infection is established, and typhoid occurs, all the other possible sources of infection become equally as important, and must be as carefully watched. It seems to us that by neglect of this principle Dr. Canney's arguments lose their force. No one will question for a moment the advisability of guarding the water supply, and adopting every precaution to ensure its sterility. and anyone who invents or designs a method of doing this, and one which is adaptable to the exigencies of active service, will have conferred a national benefit upon the country; but if, at the same time, he succeeds in drawing off attention from the possibility of other avenues of infection, he will perhaps more than counteract the good he has done. As Dr. Childs pointed out in his speech at the Medical Society, water-borne epidemics occurred with such explosive violence that they made a deep impression upon the mind of the public and the medical profession; and to this result we may add that, in civil life at all events, infection from polluted soil and such-like causes gives rise to sporadic cases which do not attract the same amount of attention. In the case of an army in encampments, however, the case is different. Even if the water supply is and remains pure, a single case of typhoid in which the dejecta are neglected may lead to the infection of soil, the infection from that to other cases, and so on, until the outbreak becomes an epidemic. There is, however, one very practical point in favour of Dr. Canney's insistence. The protection and sterilisation of the water supply is possible, the protection of an army from infected dust is practically impossible, save by withdrawing it altogether from the infected area. This, in the case of military operations, may be out of the question. Under such circumstances prophylaxis demands not alone a sterilised water supply, but the most careful attention to sanitation.

PERSONATION AND THE GENERAL MEDICAL COUNCIL.

The recent conviction of a medical impostor, named Herring, to five years' penal servitude for personation points a moral which, it is to be hoped, will linger long in the memory of the public and of the medical profession. The circumstances of the case were of an extraordinary nature, inasmuch as the prisoner, although void of the least shred of medical training, for several years carried on a medical practice under the title of the fictitious firm of "Dobie and Hoffmeister." At length the day of reckoning arrived, through the chance avenue of a coroner's inquest. As a result of the proceedings in that court the accused was prosecuted by the police for wilful and corrupt perjury in having tendered evidence as a registered medical man. Further developments led to a charge of manslaughter, which was sustained by evidence of a startling and terrible nature. It was shown at the Old Bailey last week that the prisoner treated the deceased woman, who was the subject of the inquest, for inflammation of the bowels, whereas she died of strangulated hernia. Under these circumstances the prisoner may think himself fortunate to have escaped with a conviction on the lesser charge of manslaughter. The law, however, is notoriously lenient towards offenders who injure his Majesty's lieges by the unqualified practice of medicine, either with or without the assumption of a medical title. Indeed, if any person avoid calling himself or herself a "doctor," he or she may conduct medical practice without let or hindrance. In other words, the State which carefully regulates and controls the duly qualified practitioner allows the charlatan in ninety-nine cases out of a hundred to flourish like a green bay tree at the expense of the public. Even where an impudent impostor is caught and punished, as in the case of Herring, it is usually brought about by the merest chance, and not by any proper system of safeguarding the official *Register*, even if it were compulsory for all medical men to have their names entered upon that *Register*. As pointed out emphatically in The Medical Press and Circular many years ago, the present system of medical registration is so badly framed and administered as to open the door to manifold frauds. The truth of that contention has been abundantly proved by numerous cases of personation. There can be no disguising the fact that the registration system of the General Medical Council is a failure. It is unbusinesslike, and fails in such elementary points of identification and corroboration. Under the existing conditions of medical practice in the United Kingdom there would be little difficulty in drawing up a satisfactory system of registration of qualified medical practitioners. In the opinion of many competent judges it would be necessary to make registration compulsory and its renewal periodical. The duty of maintaining the *Register* would fitly be entrusted to a body charged with the co-ordinate duty of prosecuting irregular practitioners of all kinds under powers that would have to be obtained in a new medical Act. There is little hope of any real reform at the hands of the General Medical Council. That body is by its constitution irresponsible, and in consequence it naturally enough shirks duties that would be no less anxious than toilsome in favour of the protection of the vested interests of which its members are for the most part representative. Whatever the contention of the present body may be, it is clear enough to everybody that the Council was called into existence to protect the interests of the public on the one hand and of the medical profession on the other. It seems likely, judged in the light of past experience, that neither function will be properly discharged until the Council is reconstituted upon that broad electoral basis without which it is hopeless to look for an unselfish, energetic, and progressive policy. The ideal body would be desirous of keeping in line with modern social aims and methods, while at the same time it would keep in view the popular interests entrusted to its care.

Notes on Current Topics.

Infant Mortality in France.

M. Bertillon has of late been rendering valuable assistance to the French Republic in general by drawing fresh attention to the mortality among infants supported at public charges. Some time since a law was passed entitled, in honour of its author, "La loi Théophile Roussel," which enacted that the Minister of the Interior should publish each year a detailed statement of the mortality of infants under one year of age. and especially the mortality of those who are placed out to nurse, to be weaned or brought up by hand, at the public expense. The object of, and the necessity for, this law was apparent, but, in spite of that, it was allowed to fall into desuetude, and no returns were prepared. To remedy this omission, M. Bertillon has published these statistics in a recent article in the *Revue d' Hygiène* for August of this year. From this article we learn that the mortality among infants who are between the ages of ten days and one year, and who are brought up at the public expense, was 203 per 1,000, while that of infants generally throughout the country at the same age was 128 per 1,000; consequently the mortality among the former class exceeded that among the latter by nearly 60 per cent. As a result of this state of affairs, while the birth-rate in England for the years 1874-1898 was 32·6 per 1,000, and the death-rate 19·4, the birth-rate in France during the same period only exceeded the death-rate by 1·8 per 1,000, and on several occasions of late years was actually lower than the death-rate. This is a serious state of affairs, and M. Bertillon deserves credit for having called attention to it. It is by checking such leakages of infant life—if we may so term an avoidable mortality—that France will best replenish her population. In this connection attention may be drawn to a statement made at a recent meeting of the Academy of Moral Sciences in Paris, that while the population of the rest of Europe had increased 129 per cent. during the last 100 years, the population of France had only increased 44 per cent.

The Critical Wit of a Dipsomaniac.

The professed power of curing that most obstinate distemper, habitual inebriation, led to the display of an eminently Hibernian law-suit, which was heard last week in the Skibbereen Court House, before the County Court Judge. Thomas E. Cowant, William Vincent O'Brien, and Jeremiah Twomey, trading as the "Hagey Institute" for Inebriates, Dublin, and professing to cure patients of the habit of intemperance, sued a former patient for £26 5s., being for board, lodgings, medical treatment, and attendance in the institution during the month of April, 1902. The examination of the defendant excited the risibility of both lay and professional audiences to a degree seldom witnessed even in that laughter-loving corner of the British Empire. He avowed that he had first refused to have anything to do with the Institute, and that he was led to it by his brother, after the latter had treated him to a bottle of whisky in the train. He was drunk going there, and was drunk when leaving. Mr. Twomey personally conducted him to the theatre, and then brought him back to what he called the Institute, but which defendant called a fraud. "They gave him a dose of 'gollops' the first night, and only for that he would be all right in a few days; as it was, he could not stir. He got whisky in the Institute, but he generally went across to the 'pub.' across the way, where he indulged in what stuff he liked. He left because he came down town, and meeting some friends he went on a 'terrible batter,' and did not turn up after. That was the result of his treatment at the 'Hagey.'" After the perusal of this evidence, which the defendants do not appear to have been able to rebut, we are neither surprised nor disappointed that his Honour Judge Bird dismissed the case.

Curious Sequel to a Case of Abortion.

Rigidity of the cervical tissues, sufficient in degree to delay the expulsion of the fœtus at full term, is not a very uncommon occurrence, though it is by no means as frequent as in the old days when a "rigid os" furnished the stock diagnosis of the unskilled obstetrician. In consequence of the recognition of the abuse of the term in the past, the tendency, at present, is, perhaps, to overlook the possibility of such a condition, and to endeavour to account for a delay in dilatation by any other reason. That such a condition can occur is, however, undoubted, and that it can sometimes reach a very pronounced degree is shown by a case recorded in a recent number of our latest gynæcological contemporary, *American Gynæcology*. This case was one of threatened abortion at the fourth month, in which, with the object of hastening the expulsion of the fœtus, attempts wer made to dilate the cervical canal with the Goodell-Ellinger dilator. The resistance, however, was so great that the canal could not be stretched to more than a centimetre in diameter, and further dilatation was accordingly left to the natural efforts. Twenty-four hours later the fœtus was expelled, but, on making a vaginal examination shortly afterwards, the external os was found to be unduly small. Three days later, a further and more complete examination was made, when a large oval laceration was discovered in the posterior wall of the cervix, about a centimetre from the edge of the os externum, and involving neither the os nor the vaginal vault. The fœtus, in an unruptured amniotic sac, had passed through this tear. It is difficult to account for such an occurrence save on the supposition of strong uterine contractions and extreme "rigidity" of the cervical tissues. A similar case has been recorded by Gebhard. It is probable that such cases are intimately connected with the phase of abortion known as cervical abortion—a condition which leads to extreme thinning of the cervical wall.

The London County Council and Small-pox.

THE compulsory notification of chicken-pox within the Metropolitan area has been prolonged for a period of two months from November 7th, and it is notified that the arrangement whereby certain medical men could be called in for purposes of consultation with regard to doubtful cases of small-pox will not be continued after November 6th. This looks as if the medical advisers of the London County Council did not attach much importance to the statement that a recrudescence of the epidemic is likely to occur with the advent of cold weather. We trust their scepticism will be justified by events.

Dental Antiseptics.

MR. EDMUND ROUGHTON has lately drawn attention, in the course of a series of lectures on morbid conditions of the mouth, to the importance of obtaining oral asepsis in mouth operations. The concluding words of his lecture would seem to be especially intended for the perusal of dental surgeons :—"I would strongly urge that all those who use instruments of any sorts within the mouth, should make it an invariable rule to sterilise them both before and after use." We fear that in many cases Mr. Roughton's warning remarks are far from unnecessary. Not alone among dental surgeons, but sometimes among medical men, the notion that the antiseptic power of the saliva is sufficient to counteract the effects of dirty instruments has been allowed to render the operators careless in regard to asepsis As, of necessity, dental surgeons have the largest share of mouth operations, so they furnish the greater proportion of wrong-doers in this respect. There are, of course, many dental surgeons whose asepsis is as carefully attended to as is that of an abdominal surgeon, and there are many more who adopt reasonable precautions, but, on the other hand, there are a certain proportion who, we fear, have not even the most elementary notions of the importance of, or the means of obtaining, asepsis. In consequence, every now and then, cases are met with of septic infection in connection with dental operations, though fortunately this infection is usually of a local nature. Such cases should not occur, and, if attention were only paid to the principles Mr. Roughton enunciates, would soon become things of the past.

Disinfection for Yellow Fever in Havana.

THE American occupation of Cuba has, at any rate, resulted in the carrying out of definite efforts to diminish the mortality of, or, if possible, eradicate altogether, the endemic yellow fever of that country. The establishment of the casual relation of a mosquito, the stegomyia, to yellow fever has enabled prophylactic efforts to be turned in the right direction. The first steps taken consisted in the most careful adoption of the usual methods of disinfection and quarantine, in the houses of all fever patients. Then, orders were given that all receptacles containing water were to be kept mosquito-proof, and that all stagnant collections of water which could not be drained were to be treated with oil. With the object of preventing the stegomyia, which were not thus destroyed, from biting yellow fever patients, and so becoming inoculated, all hospitals and dwellings with yellow-fever patients were thoroughly screened, and inspectors were put on guard to see that the screens were not opened ; while, in order to kill infected mosquitoes within the hospitals and houses, rigid methods of disinfection were carried out. These proceedings are very radical and must have entailed an enormous amount of trouble on the part of the sanitary authorities, so that it is satisfactory to learn that, so far as statistics relate, in consequence of them during the year 1901 there were only eighteen deaths from yellow fever, a number which is less than any since 1856.

The Tuberculous Chest.

IN examining patients in regard to the existence of pulmonary tuberculosis much valuable information may be derived from careful observation of the shape of the chest. It is generally held, even among medical men, that the shape of the chest in individuals predisposed to tuberculosis is flat, but a large number of measurements made on the living subject by Dr. Woods Hutchinson, whose results have since been confirmed by independent observations carried out by Drs. W. A. Evans and McHugh, of Chicago, tend to prove that the typical "weak chest" is deep rather than flat, resembling, in fact, the chest of an adolescent. Such a chest, moreover, is narrow above and flanges out below, to borrow the expression of the American observers, like the bottom of a fashionable coat. The tuberculous chest, then, may be described as "relatively deep and relatively narrow," the term "relatively" being used because in all such measurements it is necessary to take note of the length of the trunk. This type of chest is one associated with under-development, and this fact affords a plausible hint as to the real nature of this so-called tuberculous predisposition. The organism is one in which the tissues, including the bony framework, have failed to obtain perfect development, their powers of resistance being correspondingly reduced. If this view be correct, it has an important bearing on the prophylaxis of tuberculosis. Obviously the predisposition arises not from the extreme virulence of the bacillus but from the constitutional failure which finds expression in imperfect development, and the only hope of safeguarding these subjects from the risk of infection lies in measures having for object to reinforce their vitality. Inasmuch as in a large proportion of these cases the defective development is the result of defective hygiene and inadequate nourishment, treatment based on these principles will usually be followed by marked improvement. Even when too late to be prophylactic such measures may still be effectual in staying the hand of the destroyer.

Industrial Colonies for Consumptives.

It has long been noticed that many cases of consumption which improve very much during sanatorium treatment, on return to the ordinary conditions of life more or less speedily relapse to their former or a worse condition of health, and, indeed, the after-history of many so-called "cures" is a melancholy study. To prevent this deterioration it has been proposed from time to time that colonies of an industrial nature should be founded, to which patients might be drafted from sanatoria, when sufficiently strong, and where they might, amid healthy surroundings and under proper *régime*, be able to pursue their ordinary avocations, or, where these are unsuitable, be taught others. The work of each patient should, of course, be adapted to his particular physical ability, and the effect of his labour should be watched by competent medical authority. The expense of such a colony should not be very great, as, if cases were carefully selected, the work of the residents should contribute very largely to its maintenance. If started on a small scale in connection with some of the larger sanatoria, the success of the project could be fairly well tested before embarking on any extensive scheme, and the excellent example of the Chalfont Colony for epileptics should give some useful hints in its elaboration.

Yeast in the Treatment of Small-pox.

There was a time, not so very far removed, when barm, or beer yeast, was the most popular antiscorbutic, using this term in its non-medical signification. Even at present it rejoices in a certain prestige in the prophylactic and curative treatment of furunculosis, though data are wanting on which to base its reputation. Quite recently several Italian, French, and Spanish practitioners claim to have obtained excellent results from its use in the treatment of small-pox, which is stated under its influence to have been greatly modified in its course, being, in fact, converted into a comparatively benign affection. The treatment must be begun early, that is to say, on the first appearance of the pustules, whereupon the temperature speedily falls, the eruption runs a mild course, and recovery takes place by uninterrupted lysis, consequent upon the effect of the treatment in preventing suppuration of the vesicles. Moreover the pitting which usually follows the maturation of the ordinary pustule is conspicuous by its absence, the constitutional disturbance being reduced to a minimum. This method of treatment is reported to have given equally satisfactory results in other exanthems, *e.g.*, in measles and erysipelas, the evolution whereof is favourably modified thereby. The observations recorded in support of this view are numerous and worthy of consideration. Its action is attributed to the presence in the fluids of the body of the soluble products elaborated by the fungus which are credited with a quasi-specific influence on the micro-organisms of these diseases.

A Soldier's View of Medical Science.

Lord Roberts, at St. George's Hospital on Thursday last, took the opportunity of testifying to the good services rendered by science to the soldier. He showed that to none was gratitude more due than to those who seek to secure the best conditions for the maintenance of health in camp and quarters, and are ever ready to do their utmost to relieve the sick and tend the wounded. Modern improvements had done much, and these had been supplemented by personal devotion. Lord Roberts said he had strong admiration for the medical profession, and sympathy with the work of doctors, and in this he spoke the sentiment of the Army he had the honour to command. We trust that the Commander-in-Chief will do his utmost to secure that respect and regard should always be accorded to medical men who place their professional services at the disposal of the War Office.

Skirts, Sanity, and Sanitation.

The skirted sex have once again been discussing the advantages of "bloomers," and detailing the sanitary sins of skirts. Mankind, from the judge upon the bench to the little whooping male ragamuffin in the road, has insisted on the necessity of supporting the skirt. Womankind, it would now appear, if the privileged reporter who obtained admission to a recent solemn discussion at the Pharos Club is to be believed, has bowed to the masculine majority outwardly, but inwardly the rebellion is maintained, for confession has been made that these "rational reformers" all wear "bloomers," or what we more euphemistically term "knickerbockers," *under* the dirty, defective, and degrading skirt. Although only one lady at the recent conference ventured to appear without a skirt, that much-admired article of apparel was proclaimed as the etiological factor in many ills. Skirts impeded work, were dangerous in cycling, often led to injury or death by fire and falls downstairs, gathered filth in the streets, dragged at the legs and produced unnecessary fatigue, and required carrying so as to be an intolerable burden to women with parcels or babies. Doubtless many skirts are both artistically and hygienically defective, but, nevertheless, we think means may be found for correcting the latter without robbing the nether garment of its artistic advantages.

Miners' Phthisis and Rock Drills.

The fearful mortality from lung disease which, in years gone by, was regarded as inseparable from the occupation of mining, was markedly lessened by better provision for the ventilation of mines and by regulations having for object to check the contamination of mine air by dust; in fact, mining had been rendered a comparatively healthy, if still extremely hazardous, calling. The gradual introduction of rock drills, a step of immense importance from the point of view of efficiency, has incidentally subjected the workmen to the dust nuisance in an aggravated form. These machines produce an abundance of fine dust, the particles of which, when examined under the microscope, are seen to be beset with sharp, cutting angles. This dust, when inhaled, as it is bound to be in the absence of special precautions, exerts highly irritating effects on the pulmonary tissues and an exceedingly large proportion of the men consequently fall victims to what the late Sir Andrew Clark called fibroid phthisis, that is to say, a form of consumption resulting from long-continued irritation associated with fibroid changes in these tissues which thus become a favourable soil for the development of the specific organism of tuberculosis. The mortality from this cause in South Africa is reported to be appalling, and we have reason to believe that this mortality, and the means of preventing it, will receive the attention of the Colonial Secretary during his forthcoming visit. The means of prevention are simple and of common knowledge; all that is required is, on the one hand, to induce mine owners to insist on their adoption, and, on the other, to secure the consent of the workmen to their enforcement, for, sad to relate, the latter is by far the more difficult problem.

Diseases of the Stomach and Life Insurance.

The progress of scientific medicine and surgery is rapidly reducing the dangers of many serious maladies. In the case of ulcer of the stomach surgery now offers a reasonable chance of cure in several cases where medical treatment has proved of no avail. The common functional dyspepsia, however, are the gastric disturbances which the medical examiner for insurance is daily called upon to consider. The theoretical value of his investigation in that particular direction is unfortunately handicapped by the fact that the symptoms are almost entirely subjective; in other words, that the applicant under examination has it more or less in his power to hoodwink the physician. It is a curious fact that nowadays the state of the teeth and of the mouth generally is regarded as a powerful factor in the causation of dyspepsia, as it is of anæmia and of other general septic conditions. There are two serious diseases, at least, of the stomach which may be detected by physical examination, namely, dilated stomach and cancer. So far as the former formidable affection is concerned some recently published cases of cure by treatment with high-frequency electrical currents affords the utmost promise for future results. If a cure be thus obtainable the medical examiner will be able to eliminate one most serious condition from his disqualifying list, and submit a candidate so affected to re-examination. It is to be hoped that a similar solution awaits carcinoma of the stomach at no very distant date.

The Amateur Anæsthetist.

It is customary, when the subject of the administration of anæsthetics is under discussion, to deprecate in more or less pungent terms the assistance of the amateur anæsthetist. One can quite understand that hospital surgeons, accustomed to the highly-skilled assistance of the professed anæsthetist, experience a feeing of distrust at the prospect of having to put up with that of the average practitioner who is sometimes too timid and at times too rash in his manipulation of the drug. But almost every practitioner must be classed as an amateur anæsthetist in the sense that he lacks the training and experience of the adept; yet in the vast majority of instances the chloroform—for he always selects chloroform—has to be administered by him or not at all outside the big towns. Moreover, even in the large general hospitals of London the drug is in a large proportion of cases given by the assistant house surgeon or house physician, who are just as amateur in their way as the outside practitioner. Probably not one medical resident in a dozen in the London hospitals knows how to manipulate a Junker's inhaler or is, indeed, familiar with any other method than pouring the chloroform on to a towel or mask. We can never hope to make the average student an expert anæsthetist, no matter what pains are taken to instruct him in this department, for the simple reason that he does not get enough practice to keep him in training. After all, amateurishness in this sense is not fatal to the safe induction of anæsthesia provided the administrator be a man with a cool head and of careful habits, otherwise the mortality from this cause would be vastly greater than it is, and it is already unduly high, as our weekly record shows.

Arsenical Poisoning in Medical Practice.

The question of arsenical poisoning has been brought prominently before the public by a case still under investigation. So far as the evidence extends, whether the suspicions of the police prove to be well founded or the reverse, the possibility of such an occurrence suggests the likelihood of a medical practitioner overlooking a case of poisoning by arsenic. Under circumstances of intentional poisoning the symptoms are usually chronic, that is to say, they are far less pronounced than those of acute poisoning. In criminal administration the utmost care is usually taken to lull suspicion, and the medical attendant, however observant he may be, has no clue afforded him as to the real state of affairs by the conduct of nurses and friends of the patient. It is therefore hardly surprising that the progressive emaciation and bowel irritation are often referred to some obscure intestinal inflammation. Indeed, so misleading are the symptoms of chronic arsenical poisoning, especially in view of the fact that the course of symptoms is often irregular and atypical, that the detection by a medical attendant of the condition would rank as a distinguished diagnostic fever. When suspicions are once aroused the whole thing is capable of the readiest scientific investigation. It often happens, however, that suspicion is, so to speak, cumulative, and that the existence of criminal intent is arrived at only after a series of mysterious deaths. The cautious medical practitioner, bearing these facts in mind, will do well to test for arsenic when he is called upon to attend any chronic bowel disease incapable of satisfactory explanation in the light of ordinary experience. An analysis of the fæces would speedily furnish the key in cases of arsenical poisoning.

Another Poor-law Lunacy Scandal.

That Poor-law lunatic nursing is in need of somewhat drastic reform has long been a deep-rooted conviction of the man in the street. South London appears to be waking up to the necessity of treating offending officials with the strong hand. A few weeks since the Southwark Board of Guardians dismissed several nurses in connection with the discovery of unreported bruises upon the body of an ancient female pauper. The woman in question has since died, and at the subsequent inquest some startling evidence was tendered as to the treatment of inmates by nurses. The jury found that death was due to exhaustion and heart failure, and that there was no evidence to show how the bruises were caused. That view, however, seems hardly consonant with the testimony of a witness to the effect that one of the dismissed nurses struck the deceased two heavy blows on the stomach with her fists. The fact of the bruisés having been unreported lends a certain amount of colour to the theory that violence was committed. In any case the matter can hardly be allowed to remain in its present unsatisfactory position. It is announced that a member of the Southwark Board of Guardians, the Rev. W. J. Somerville, has appealed to the Local Government Board for an opportunity of presenting an appeal from the dismissed nurses, and offering to pay any legal expenses of such a course. The unwisdom of such a proposal must be evident to all who are acquainted with the necessary conditions of lunacy discipline. No one appears to have denied that the bruises were unreported to the medical authorities of the infirmary, and it is clear that an omission of that kind, were it allowed, would open the door to brutalities of a kind that are now happily rare in the asylums of the United Kingdom.

Sentiment and Surgery.

Every medical practitioner knows how largely the feeling of sentiment enters into the question of surgical operation. He is naturally concerned with the practical expression of that mental state so far as it influences the determination of patients or their friends with regard to procedures that he himself holds to be necessary. It would be interesting, and to some extent profitable, were it possible to trace the ultimate origin of this widespread sentimental objection to surgical operation. The excessive mortality that formerly attended anything of the kind in pre-aseptic days accounts for a great deal in the sum total of popular conviction. Before the advent of Listerian methods a wound or the removal of a finger-tip might sooner or later lead to death. The fear of excessive mortality after surgical operation has happily been done away with for ever, thanks to the genius of our distinguished countryman, Lord Lister. There are other deep-rooted motives at work, however, in the formation of the particular sentiment under discussion. The dread of personal deformity or mutilation, for instance, is often so great as to render the chances of death preferable as an alternative, more especially, perhaps, in the case of women. On the whole, it may be said that to overcome sentimental objections to necessary surgical interference is one of the most delicate yet indispensable duties which the medical man owes to society in general and to his patients in particular.

The Cooling of Houses.

A vast amount of ingenuity has been expended in the heating of houses, whereby the average citizen is enabled to defy the rigours of winter within his well-warmed castle. Little has been done, however, to counteract the opposite extreme of temperature, and enable him to live indoors in comfort despite the tropical heat of summer that is scorching up the outside world. In Baltimore it has been recently announced that a company has been formed for the purpose of house-cooling. Pipes are laid under the streets, and cold air distributed to consumers at a fixed charge, in much the same way that applies to gas or to electricity. The idea is simple, and likely to prove a commercial success in countries where a hot and long summer is the rule. In the United Kingdom a hot-air supply is needed far more than a cold, and it seems somewhat curious that in these days of manifold catering no agency for distributing heated air for domestic purposes has been started in some, at least, of our great centres of population. There is much to be said in favour of such a system, especially on the grounds of cleanliness, and the saving of labour in the household, to say nothing of the disproportionate and excessive cost of coal and other fuel in recent years. It may be interesting to recall the fact that the Houses of Parliament are supplied both with cold and with warm air, as may be required, by means of an elaborate system of purifying and of warming or cooling inter-chambers.

Changes in the Surgical Staff at King's College Hospital.

After a period of service in King's College, London, extending over twenty-five years, Professor William Rose, B.S., M.B., F.R.C.S., has resigned his appointments as Professor of Clinical Surgery and Senior Surgeon to the Hospital, and in place thereof has received those of Member of Council, Emeritus Professor of Surgery to King's College, as well as that of Consulting Surgeon to the Hospital. It is well that the College should thus honour one of its own students, for throughout his career Professor Rose has been associated with it. Entering as a student when Sir Wm. Fergusson was at the zenith of his career, Rose became a dresser, and finally a house surgeon, to the late baronet. Subsequently he became surgical registrar, was noted for his teaching ability, as well as for his manual dexterity, and was appointed to the staff in 1876. On the retirement of Mr. Henry Smith in 1889 he was elected Professor of Surgery, and on Lord Lister's retirement in 1891 he was appointed to the chair of clinical surgery, and became Senior Surgeon to the Hospital. He had already won for himself the reputation of being one of the most brilliant operators of the Metropolis, and his skill received general recognition. The ability which enabled him first to attack the Gasserian ganglion ought not to be lost to the service of humanity. We are glad to know that Professor Rose entertains no thought of retirement from practice, and that his other appointments will be retained. The rearrangement on the staff of King's promotes Mr. W. Watson Cheyne to the Professorship of Clinical Surgery, whilst Mr. Albert Carless becomes Professor of Surgery and Surgeon with charge of in-patients to the Hospital.

An order has been issued by the Local Government Board presenting regulations with regard to the use of small-pox hospitals for purposes of medical instruction.

The next session of the General Medical Council will open on Tuesday, the 25th inst.

PERSONAL.

Dr. Lapponi, the medical adviser to his Holiness the Pope, was announced last week to be suffering from appendicitis, and he has since been successfully operated upon for its relief by Professor Mazzoni.

Dr. W. H. Clements, late District Medical Officer, Southern Nigeria, has been appointed District Commissioner and Government Medical Officer at Cockburn Harbour, in the Turks and Caicos Islands, West Indies.

After some years' labour in Melbourne, Dr. Wolfe is about to resume practice in Glasgow, the field of his former operations, whence he had sent forth those surgical innovations on operations on the retina, conjunctival and skin translation, which have become classic, and with which his name is associated.

The name of Major F. S. Heuston, R.A.M.C., F.R.C.S., was inadvertently omitted from our list last week of members of the medical profession who were presented to his Majesty at the recent Investiture. Major Heuston, who is at present in charge of the Royal Hospital, Kilmainham, was on that occasion invested with the Order of C.M.G.

Dr. John Strachan, who has just resigned the Bishopric of Rangoon, says the *Westminster Gazette*, is one of numerous members of the medical profession who have risen to distinction in the Anglican Church, the best-known being Dr. Hicks, the Cambridge don, who became Bishop of Bloemfontein. Bishop Strachan took his M.D. degree at Edinburgh University, as gold medalist, and has had some connection with scientific education in India as a Fellow of the University of Madras.

Mr. George Brown, M.R.C.S., member of the General Medical Council, is stated to be on the point of relinquishing private practice, it being his intention to move to Cornwall. Mr. Brown has, for more years than we can remember, been a strenuous and uncompromising advocate of the rights of the general practitioner, whom he has represented as an elected representative in the General Medical Council for several years past. He is also known to the profession as for upwards of a quarter of a century the genial editor of the *Students' Journal*, since merged into the *Hospital Gazette.*

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

SCOTLAND.

[from our own correspondent.]

Royal Medical Society.—Sir John Halliday Croom, President of the Royal College of Surgeons, Edinburgh, delivered the inaugural address in connection with the opening of the 166th session of this society on October 31st. Sir Halliday Croom referred to the pride which members of the society felt in its traditions. Founded as far back as 1734, it originally consisted of six members, who met informally once a fortnight, and in 1737 it was formally constituted with a membership of ten select students who met weekly in a tavern, the election of new members requiring the unanimous consent of the society. In 1763 the meetings took place in a room in the old Royal Infirmary. It was when the society was adorned by Cullen, Gregory, Duncan, and Gilbert Blane that the suggestion was first made to build a hall of its own, and it was of interest that the first hall was erected on the site of the present College of Surgeons. This was opened in 1766; the present building in Melbourne Place had been in use exactly fifty years. Few societies had enrolled greater or nobler names in medicine than their society had—William Cullen, Joseph Black, Haller, the Monros, Mungo Park, the explorer, Sir Charles Hastings, Darwin, Sir Gilbert Blane (who in 1775 read a dissertation on "The Nature of Antiseptics, and How They Operate," thereby anticipating to some extent what was written by Lister), and, nearer our own time, Marshall Hall, Sharpey, and Carpenter. The two names that within his own time stood out as great landmarks of medicine and surgery were those of Simpson and Lister, the one by stilling pain, and the other by making the scope of surgery boundless. Those men, thanks to whom the grim terrors of surgery had disappeared, were trained in the society. In the bosom of the society had also been nurtured men who were famous in letters. Possibly Oliver Goldsmith, during the first two years he spent in Edinburgh, first got his afflatus to write "The Vicar of Wakefield" and "The Deserted Village." Probably in that old tavern in the town to which he had alluded the pompous pedant Akenside, sketched to the life in "Peregrine Pickle," got his first inklings of the "Pleasures of the Imagination"; and perhaps it was in some heated discussion in that very society that the "Origin of Species" first dawned upon Darwin. Proceeding to speak of the value of the Royal Medical Society as an adjunct to the Medical School, the speaker remarked that a lecture was often forgotten, but a subject threshed out among themselves they were not likely to let slip. They might go heedless to their examinations, but they would think twice before appearing among their fellows insufficiently prepared, or running the risk of a pleasantry at their own expense. The preparation for the battle of life lay not so much in learning professional work as in learning how to treat their fellows and their patients. Therein the society was particularly helpful, and perhaps had Mr. Rhodes seen how good a substitute it was for the much-vaunted residential system of their sister colleges in England, he might have allowed his first thoughts towards Edinburgh to take effect, and not have encumbered his alma mater with the founding of a medical school which could never be anything but second rank. The society helped its members to learn something of human nature, and many a man whose capacity was beyond dispute had failed in life for want of that knowledge. In their turn the members could do much for their society and alma mater. While in other countries University education and equipment were the care of the State, they in Scotland were in great measure left to their own resources, and were dependent for prosperity on the chance munificence of some old alumnus, some generous philanthropist, some open-handed millionaire. He hoped that in after life they would never lose an opportunity of pleading the cause of Edinburgh.

Edinburgh University General Council.—At the last half-yearly meeting of the Council, Dr. Ernest Greville moved a resolution that the right of voting by ballot be accorded to the members whenever that method was requested by the mover or seconder of a resolution. His desire was to remove one of the disabilities under which the graduates laboured. Their grievance was that they were practically denied all real representation in the councils of the University, and though they might pass resolutions unanimously the Court could ignore them. Small as their representation was, it was rendered smaller by the procedure. By voting by show of hands they advertised themselves as antagonistic to the governing few. The medical assistants were tied by the conditions of tenure of their appointments and could do nothing to improve the teaching, lest they should bring themselves into opposition with those who considered the present system perfect, and thus run the risk of losing their appointments. An amendment, substantially Dr. Greville's motion, was carried by twenty-two votes to eight for the previous question. A second motion of Dr. Greville's—That members of the General Council be allowed reasonable opportunity of ascertaining the opinions of candidates seeking election as Assessors to the University Court—was carried almost unanimously.

Edinburgh University Rectorial Election.—The result of the polling was announced shortly after noon on November 1st, the figures being:—Sir Robert Finlay, 916; Sir Edward Grey, 621—a Unionist majority of 295.

BELFAST.

[From our own Correspondent.]

Royal Constabulary Medical Officer.—The late Dr. Daniel McDonnell, having been one of the five medical officers to the police force in this city, a vacancy was caused by his death. There was a large number of applicants for the post, but as it was generally understood that it would be given to a Roman Catholic the candidates in the running were only four or five in number. Dr. W. J. Maguire has been appointed.

Belfast Workhouse.—A most amusing document has been published in the local papers—the report of a special committee of the guardians appointed to consider the report of the Local Government Board inspector. The members of the committee consider that Mr. Agnew, the inspector, has not done justice to their efforts at improving the workhouse and its management during the last three and a half years, or, as they put it, "since the good old times when the knights and squires ruled the roost, assisted by other guardians elected under a corrupt system of voting." Referring to the old arrangements, they say, "They will not harrow the public mind by attempting a description of their utter mockery." It is as well they do not, for the grammar and composition of this report is quite sufficiently harrowing to our mind. Certainly if all their claims can be substantiated the improvements in the period named have been very great—much more room, a larger medical staff, a staff of trained nurses instead of pauper attendants, strict limiting of visitors instead of indiscriminate visiting at all hours, waste checked, and order and decorum well observed. It sounds very nice, but we have our doubts. No doubt the medical and nursing staffs have been enlarged and the buildings improved, but on the day that this report was presented it was stated that two male inmates had been found drunk on the premises at 7 o'clock in the morning, having been seen sober at 3 a.m. As for waste, a letter was read from the Local Government Board on the sugar supply. The fact is not denied that over one ton and a half of refined sugar, costing £50 4s. 6d., was ordered during one half-year, though the compounder of medicines admitted that he did not use more than two shillings' worth in a year for the purpose for which it was placed on the list, namely, the compounding of medicine. The Local Government Board has accepted the visiting medical officer's repudiation of having acted with any want of bona-fides in the matter.

Small-pox Hospital at Purdysburn.—This hospital is now ready for use, and a portion of it is being furnished, including eight beds for patients and two rooms for suspected cases. The city authorities have made an arrangement with the guardians by which the latter will supply the resident staff when needed, the Corporation paying them. The remuneration will be five guineas per week for the resident medical officer, two and a half guineas per week to the senior nurse, and two guineas per week to other nurses. With regard to the remuneration of the visiting medical officer, Dr. Robb, this cannot be settled beforehand, as it will depend on the amount of work to be done, and Dr. Robb is willing to leave himself in the hands of the Public Health Committee.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

A NEW SIGN OF PARALYSIS OF THE INTESTINE.

To the Editor of "The Medical Press and Circular."

Sir,—I have read with interest, in the current issue of The Medical Press and Circular, an account of the discovery by Dr. G. Peters, of Toronto, of a hitherto undescribed physical sign—diagnostic of the condition of paralysis of the muscular coats of the intestinal wall. This new physical addition to our clinical armamentarium depends, we are told, on the existence, during the paralytic condition of the intestinal coats, "of increased telephonic properties of the inflamed abdomen." (I may remark, in passing, that the term "inflamed abdomen" is somewhat unusually comprehensive, and even postulates the existence of a state of things which has never yet been produced by disease). The special peculiarity in the new physical sign described by Dr. Peters lies, however, in the explanation offered: that "by reason of its flaccid and atonic condition, the entire intestine is, acoustically considered, a continuous column of gas, which thus acts "on the precise principle of a stethoscope,' the rigid abdominal walls acting as a sounding-board." This statement of the view of Dr. Peters involves a misappreciation of "the precise principle of a stethoscope," which, I venture to suggest, should not be allowed to go forth to the professional reading public without question. Most readers of THE MEDICAL PRESS AND CIRCULAR are, doubtless, acquainted with the history of the invention of the stethoscope, and of its introduction into clinical practice. Also, with the fact that the use of "immediate" auscultation had been reported on by the "Father of Medicine" himself; but that its application, if not left in absolute abeyance, had remained barren of definite results. Also, how one of the most inspired benefactors of suffering humanity suddenly developed the idea of the stethoscope, when consulted by a young lady whose combined stoutness and shyness precluded the practice of immediate auscultation to the infra-mammary region; which he, evidently, had been in the habit of employing in at least some cases of thoracic disease. And how, on the inspiration of the moment, recollecting how easily the scratching of a pin could be heard at the end of a long beam of timber, when the ear was applied to the other extremity, he took up a quire of paper which happened to lie on his desk, rolled it up in the form of a tube, and, on applying one end to the chest, and placing his ear in contact with the other, he was equally surprised and delighted to find how distinctly the various intra-thoracic sounds were conducted. But there are some other important facts in the physical history of the stethoscope, which seem to be less familiarly known, and which are not, so far as I can remember, duly emphasised in any of our English text-books of the "theory and practice of medicine." One of these is that, to the end of his clinical career, although like an untiring enthusiast, he tried the stethoscopic properties of almost every available form of matter, the inventor estimated the results obtainable with the original *paper* instrument almost as highly as any. Another is that, although *metals* are, as is well known to every experimentalist in the domain of acoustics, the best and purest conductors of sound, Laennec finally selected the fairly *soft and porous woods*, such as cedar, as the best materials for the clinical stethoscope, because the rather aggressive sharp *metallic tinkle* superadded a somewhat unnatural "clang-tint" to the intra-thoracic auditory phenomena. But the very important fact—and "the interpretation thereof"—which seems to be least known of all in this connection, and which I cannot at this moment remember having ever seen pointed out or explained in any of our English text-books, is: *Why Laennec always used a* HOLLOW *stethoscope.*

The late Dr. William Stokes, of Dublin, who, fortunately for himself and for the Dublin School of Medicine, happened to be a pupil of Laennec at the auspicious period which enabled him to become the young apostle of the stethoscope to the English-speaking public, used to tell at his cliniques how, when he first showed a stethoscope to a prosperous senior practitioner of the old school, the latter at once held it up to the light and —looked through it! The first impression made by the appearance of the new clinical instrument, very evidently was, that it was intended to supply some optical revelations! In the former years of my own personal experience, senior medical students have consulted me on the mysteries of the stethoscope, who laboured under the belief that the thoracic sounds were transmitted through its tubular air space. I incline to the belief that some senior practitioners still hold, somewhat indefinitely, the same opinion. In the present (more enlightened) period of quinquennial medical curricula, we must (charitably) believe that no practitioner obtains a diploma without having—long before —mastered the very elementary physical fact that sounds are transmitted along the stethoscope by the solid—not the gaseous—medium.

Of the three recognised forms of matter *gases* are, notably, the worst conductors of sound, *fluids* are less bad, and *solids* are by far the best. The first essential property of a conductor is *homogeneity*. Accordingly, the worst form of conductor available—after an approximate vacuum—is one formed of alternating layers, or spaces of matter of various composition, density, and elasticity. After prolonged and varied experimentation on the different media of which stethoscopes might be constructed, both hollow and solid, Laennec found that the various forms of vocal resonance—in health and disease—were best transmitted to the ear of the auscultator through a *tubular* stethoscope. The very important pathological acoustic signs of *bronchophony*, *pectoriloquy*, and *ægophony* would be satisfactorily recognised only by the use of an instrument of this construction. In few words, the tubular stethoscope functions as a *speaking tube*, as well as an ordinary conductor of acoustic waves, by preventing the dispersion of the energy of the vocal vibrations in every circumferential direction. The utilisation of the acoustic theory of the stethoscope was completely carried out by the late accomplished Dublin physician, Dr. Haydon, of the Mater Misericordiæ Hospital, who constructed his own form of the instrument of a single perforated piece of wood—thus giving the ideal combination of the continuous *solid conductor* and the *speaking-tube*—fairly widened at the distal end for application to the ear. And this construction of the instrument was still further improved by his colleague, Sir Francis Cruise, one of the most accomplished of living physicians, who, by the addition of a conveniently broad "removable" ear-piece to a fairly expanded aural extremity, gave the utmost available area of contact with the prominences of the auricle—combined with the desirable facility of conveyance in the pocket of the practitioner.

The comment on the "*discovery*" of Dr. Peters, which elicited these remarks, leaves the impression, on my mind at least, that the essential conductor in stethoscopic observation is the imprisoned column of air—which notion is *not* in accordance with physical facts, nor with the teachings of the inventor of the stethoscope, nor of his enlightened successors and representatives.

I am, Sir, yours truly,
JOHN KNOTT, M.D.

34, York Street, Dublin, November 1st, 1902.

Literature.

TEXT-BOOK OF ANATOMY. (a)

THOSE who have looked forward to the publication of this important work have been afforded a rare treat by its perusal. We may say at once, that it undoubtedly marks a great advance in the teaching of anatomy. One is sometimes tempted to think that with such a multitude of text-books on such a subject as anatomy there can be no room for new ones, yet the study of a book like this will convince the most sceptical that there was ample room for it. The book is dedicated to Sir Wm. Turner. No fewer than nine British anatomists, holding high positions in different teaching centres, have been associated with the Editor in contributing the various articles. They are all, with one exception, "sons" of Sir Wm. Turner and the Edinburgh School, and the remaining one may be regarded as a legitimate and worthy grandson. The Editor is the largest individual contributor. He has furnished articles on the brain and spinal cord (195 pages), and also those on the respiratory system and the ductless glands. They are all stamped with the accuracy and elaborateness of detail which one would expect who is familiar with the writings of this great master of descriptive anatomy. The many clear and carefully-selected diagrams in the first of these articles will prove of the greatest assistance to students in their efforts to overcome the difficulties of this important part of the subject. We notice that the Editor makes practically no use of colours in any of the many illustrations which adorn his text, and we think that in this he has exercised a wise discretion. It is impossible in a short review of such a great work as this is to do more than briefly notice a few of the points which struck us as we looked through its pages. There is a wonderful harmony between the various sections, even the styles in which they are written present no abrupt contrasts. The development of most of the bones is illustrated in an attractive and striking manner by the use of tasteful colours; curiously, one of the bones in the description of which we notice this method is not applied is the temporal, whose intricacies of development most puzzles the average student. We are glad to see that the subject of the architecture of bones has been systematically dealt with, it seems a pity, however, that some illustrations of these in which the arrangement is recognised as of great practical importance have not been included, and some reference made to the subject in the article on surgical anatomy. We notice that on the subject of the motor and sensory distribution of the spinal nerves, Professor Paterson appears to hold widely different opinions from Kocher, with whom Thorburn (in 1899) has in the main expressed agreement. The organs of special sense have been most clearly and judiciously described by Professor Howden: nothing important has been omitted, and a careful preservation of perspective has been observed. The greatest care has been taken in the article on the vascular system by Professors Young and Robinson in that most difficult subject of the development of the blood vascular system to make the descriptions clear by the use of an ingenious system of coloured diagrams. Probably greater divergence of opinion will be expressed in connection with Professor Birmingham's article on the digestive system than with any other part of the book. A relatively wide range must be allowed in laying down the positions of the viscera of the abdominal cavity, and the topographical anatomy is rendered thereby all the more difficult to describe. Professor Birmingham has, in our opinion, succeeded admirably. The mid-Poupart lines have disappeared in the description of the regions of the abdomen, and their places are taken by the Poupart lines drawn vertically upwards from a point midway between the anterior superior spine of the ilium and the symphysis pubis. It seems a pity that illustrations should have been taken from a subject in which it is admitted the liver and cæcum extended lower down than normal. Some notable discrepancies appear between the illustrations in this section and those in the article on surface and surgical anatomy. To the anatomist they are in themselves interesting as showing how variable may be the conditions found without the variations amounting to what need be called pathological; the student, we trust, may learn the same lesson and not be dismayed. The only portion of the book which appears to suffer from compression apart from that devoted to surgical anatomy, in which case it was from the nature and extent of the subject necessary, is that on the urogenital system by Professor Dixon. Possibly the student will think there is enough and to spare provided for his digestion, yet, comparing this subject with others, the subject might well have occupied at least twenty more pages. The constitution of the "middle" lobe of the prostate is clearly described in the text, yet each illustration of the parts seen on the mesial section of the pelvis with its contents, shows equally clearly a division between this portion of the prostate and the lateral portions, which division should admittedly only show in the lines of the common ejaculatory ducts.

(a) "Text-Book of Anatomy." Edited by D. J. Cunningham, M.D., F.R.S., Professor of Anatomy and Chirurgery, Trinity College, Dublin. In One Volume, royal 8vo, extra cloth. Pp. xxxii., 1,309, with 824 Engravings. The articles are contributed by Professor A. H. Young (Manchester), Professor Arthur Thomson (Oxford), Dr. D. H. Hepburn and Dr. Harold Stiles (Edinburgh), Professor A. M. Paterson (Liverpool), Professor R Howden (Newcastle), Professor A. Birmingham (Dublin), Professor A. F. Dixon (Cardiff), and the Editor. Edinburgh and London: Young J. Pentland.

The indexing has been very satisfactorily done by Dr. S. W. P. Lawrence. It would, however, be an improvement if, where several references to pages appear after a title in the index, the number of the page bearing the major reference were printed in heavier type. This plan renders the work of looking up subjects much lighter. We think a great addition to the usefulness of the book might be made by the insertion of a section dealing with the study of anatomy as it is learned and taught in the dissecting-room. It is true there are already books provided for the special purpose of assisting the student in this part of his work, but there are also excellent books devoted to the study of applied anatomy, and yet this is not held to obviate the necessity for a section of seventy-five pages on surface and surgical anatomy, with several full page illustrations in Professor Cunningham's book. It can scarcely be contended that this important subject of surgical anatomy, though exceedingly well introduced, is anything like exhausted by Mr. Harold Stiles. Nor do we think the section we contemplate on the subject of anatomy as it is taught in the dissecting room need be xhaustive.

eThe general tendency on the part of students is to depend too much on their books on "Practical Anatomy"; some never open any chapter of a systematic anatomy except the one on osteology, the result being that many never get a connected view of the subject, which remains for ever for them a disjointed collection of "parts." The inclusion of such a chapter should be comparatively easy seeing that the arrangements for dissections in most schools in Great Britain are at present adopted from those of Edinburgh, and therefore fairly uniform.

This latest addition to the long list of text-books of anatomy is profusely illustrated. Mr. Murray's work shows the highest skill in emphasising the points desired to be made in each illustration, while the accessory portions are worked up with every attention to accuracy of detail. The less highly coloured illustrations in the chapter on surface anatomy, for instance, are artistic gems. The Editor in his preface pays a well deserved tribute to the ability of Mr. Murray, who has drawn all the illustrations except those in two of the articles. The engraving must be held responsible for a certain amount of unevenness in the quality of different pictures in the same sections. A very successful future is guaranteed for this text-book, which will immediately take its place as one of the leading works on anatomy in the English language.

HAIG ON FOOD AND DIET. (*a*)

Though the reader may not be prepared to accept as physiological truth all that is stated in this interesting book, yet there can be left little doubt of the author's sincerity. Dr. Haig writes as one thoroughly convinced in his own mind, and this cannot fail to impress those who may seek his advice. The statement in the preface that ignorance in matters of diet is the cause of a hideous waste of time and money, as well as of mental and moral obliquities, naturally leads the reader eagerly to see how these terrible evils may be averted by a reformed system of diet.

The tables of tracings show how, as fresh albumens are introduced into the blood available for production of force, up goes the urea curve with corresponding increase in the power of producing force.

The sources whence the nutritive albumen are to be derived is the great point. Beef tea and meat extracts are termed "deadly decoctions of flesh." They abound in uric acid and act but as transient stimulants, as also do tea, coffee, and cocoa. What, then, is the patient to live upon? Milk, cheese, nuts, almonds, and various bread-stuffs are to take the place of flesh food, and in support of this vegetarian diet the author quotes the walking match from Dresden to Berlin in May, 1902.

(*a*) "Diet and Food, Considered in Relation to Strength and Power of Endurance, Training and Athletics." By Alexander Haig, M.A., M.D.Oxon., F.R.C.P. Fourth Edition. London: J. and A. Churchill. 1902.

Six vegetarians came in in front and gained an easy victory over the flesh-eaters.

The author's own personal experience shows how much good he has derived from his very simple diet. We believe the truth to be that there are many persons who would derive immense benefit from giving up meat and alcohol, while undoubtedly there is another class who suffer from amylaceous dyspepsia who become changed for the better in a remarkable way when living on rarely-cooked meat, with toast and hot water for drink.

Dr. Haig's book, at any rate, furnishes much valuable food for both physiologist, physician, and chemist, and is very well worth careful study.

BLUMFELD ON ANÆSTHETICS. (*a*)

We congratulate the author on producing the best handbook on Anæsthetics that has yet appeared. It is practical and didactic, the accepted theories of the London school are put before the student, and he is not bothered with conflicting theories. We are particularly pleased with Chapter IV., treating of the administration of chloroform; if its directions are strictly followed we shall less frequently see the heading, "Death under Chloroform." We are not to be taken as approving of everything the author teaches; we differ widely from him on the relative merits of ether and chloroform, but withal we think that for those who accept the opinion of London anæsthetists the book is as near perfection as a practical handbook on the subject can be.

THE COMBAT WITH CONSUMPTION. (*b*)

Last year's British Congress on Tuberculosis was epoch marking. It fixed a milestone in the uphill journey of the race. It aroused a new spirit, and lent energy to many efforts making for the uplifting of the human. Men of all nations gathered at the review, at which weapons were examined and methods of campaign discussed whereby a successful warfare might be waged with the "great white plague." Now, within a year of the Congress, we are favoured with the bulky but exceedingly valuable "Transactions" of the great gathering. They appear in four volumes. The second deals with the work conducted in the State Section, and the fourth with the consideration of the Veterinary Section.

Medical men will find their chief interest in volume three. Here the report of the Medical Section is found edited by Dr. Hector Mackenzie and Sir Hugh R. Beevor; and here also is the record of the work of the Pathological Section, edited by Dr. J. J. Perkins. The volume teems with material rich in facts and abounding with suggestions. It contains the detailed reports of valuable discussions on climatology, the therapeutic and diagnostic value of tuberculin in human tuberculosis, sanatorium treatment, the use of the Röntgen rays, the relations of the bacillus tuberculosis, the conveyance of tuberculosis by milk, the varieties of tuberculosis, and mixed infections.

The various papers presented to the Congress are here given in full, but among so many of exceptional interest and value it is impossible to single out particular articles for praise.

These volumes will long remain as worthy monuments marking a combined and concentrated effort to secure means for the extermination of a scourge which bars human progress. Everyone in any way concerned in the publication of these records merits high praise, and we particularly congratulate the Honorary Secretary-General and his staff of workers on the way in which they have upheld the dignity and influence of British medicine, and manifested to the whole world the scientific spirit and keen humanitarian instincts which stimulate workers in this country.

THE EXAMINATION OF THE BLOOD. (*a*)

During recent years hæmatology has proved a particularly fascinating field for enthusiastic investigators. Systematic examination of the blood has thrown much light on many problems connected with hæmopathology. Modern methods have greatly facilitated research, and clinical accuracy has been brought nearer. Not only have greater powers been secured for diagnosis, but in not a few diseases useful guides to prognosis have been discovered. Among the many valuable works dealing with affections of the blood and methods for their investigation, which have appeared during the last few years that of Dr. Coles justly occupies a prominent place, and the fact that a second edition is now called for affords evidence of its usefulness.

The work makes no claim to originality but is a judiciously arranged and thoroughly trustworthy compilation of much of the best literature of the subject. Dr. Coles, however, has devoted much attention to the technique of the subject, and one cannot but regret that he has refrained to a great extent from expressing his own views. The book is peculiarly suited to the needs of the practitioner or the student seriously entering on the study of hæmatology. The practical methods are well presented and the clinical deductions obtained from the examination of the blood clearly expressed. The book has been thoroughly revised and much new matter added, particularly on recent methods for the detection of malarial and filarial parasites. Dr. Coles still advocates the use of slides rather than cover glasses in the preparation of blood films. He also prefers the eosin and hæmatoxylene method of staining, but gives particulars concerning the very satisfactory eosin-methylene-blue stains introduced by Jenner and Leishman.

The sections on the general morphology of the blood are particularly deserving of commendation. It is, however, unfortunate that the descriptions of the very excellent plates should have been placed after the table of contents, and not, as should have been the case, in close proximity to the figures. The description of the blood in various diseases is on the whole satisfactory, although the discussion of the pathology of certain of the blood diseases is meagre. We venture to think Dr. Coles does not present sufficient evidence to support his contention that chlorosis occurs "in boys in a somewhat modified form." We are sorry to find no reference to Tallquist's very convenient and clinically useful hæmoglobin scale. Exception, we think, may be taken to a group of "simple primary anæmia" with anything like uniform pathology. We could have wished that Dr. Coles had more clearly indicated the reasons which lead many to consider spleno-medullary leucocythæmia and lymphæmia absolutely distinct affections, and not merely two "forms" of the one disease. A differential chart indicating the chief characters of the more important forms of anæmia should prove of much service for ready reference. The section on the blood in malaria will also prove of considerable clinical service.

A short bibliography is given, but a little care would have much increased its value. But in spite of limitations and manifest shortcomings the book is a notable one, and admirably meets the needs of those for whom it was written.

HEWLETT ON BACTERIOLOGY. (*b*)

The first edition of Professor Hewlett's work on bacteriology was so well known and so much appreciated that it is no wonder that within a comparatively short time a second edition has been called for. In this new edition, the text has been carefully revised throughout,

---

(*a*) "Anæsthetics; a Practical Handbook." By J. Blumfeld, M.D.Cantab., Assistant Anæsthetist to St. George's Hospital; Anæsthetist to the Grosvenor Hospital for Women and Children, London. London: Baillière, Tindall and Cox. Pp. 109. Price 2s. 6d. 1902.

(*b*) "Transactions of the British Congress on Tuberculosis for the Prevention of Consumption." In Four Volumes. London: William Clowes and Son, Limited 1902.

(*a*) "The Blood: How to Examine and Diagnose its Diseases." By Alfred C. Coles, M.D., B.Sc. Second Edition. Pp. 286. With six coloured plates. London: J. and A. Churchill. 1902. Price 10s. 6d.

(*b*) "A Manual of Bacteriology, Clinical and Applied, with an Appendix on Bacterial Remedies, &c." By Richard T. Hewlett, M.D., M.R.C.P., D.P.H., Professor of General Pathology and Bacteriology, King's College Hospital; Physician to the Seamen's Hospital, Greenwich, &c. Second Edition. Pp. xiii. and 535. With numerous Plates and Illustrations. London: J. and A. Churchill. 1902.

several sections have been re-written, and the whole work brought up to date. The volume still maintains its handy form, and will not only maintain but increase its former reputation.

The chapter on suppuration and septic conditions is particularly good, and contains a clear and practical description of the method of procedure which should be adopted in determining the nature of the infecting bacteria in pus and other discharges. Professor Hewlett draws attention to the importance of cultivation experiments in making a diagnosis of the presence or absence of gonococcus, as by this means alone is it possible to distinguish it from the *diplococcus intracellularis meningitidis* of Weichselbaum.

We should like to make one suggestion, which may or may not be considered of value. Micro-photographs are excellent means of reproducing microscopical specimens for the benefit of those who are familiar with the appearances of the specimens thus reproduced, but they are not sufficiently clear to afford one-half the instruction to students that a good diagram will afford. If, however, a clearly-drawn diagram of each micro-photograph was placed beside the latter, the advantage to the student would be very great, as he would be then furnished with a much-needed key to the photograph, and so be able to determine more exactly the nature of the different structures which he sees.

NEW BOOKS AND NEW EDITIONS.

The following have been received since the publication of our last list:—

Bailliere, Tindall and Cox (London).

Text-book of Diseases of the Ear and Adjacent Organs. By Professor Dr. Adam Politzer, of Vienna. Translated under the Author's supervision by Milton J. Ballin, Ph.D., M.D., and Clarence L. Heller, M.D. Fourth Edition. Revised, with 343 original illustrations. Pp. 900. Price 25s.

Anæsthetics: a Practical Handbook. Vol. VII. of the Medical Monograph Series. By J. Blumfeld, M.D.Cantab. Pp. 109. Price 2s. 6d.

The Theory and Practice of Infant Feeding, with Notes on Development. By Henry Dwight Chapin, A.M., M.D. With numerous illustrations. Pp. 326. Price 10s. 6d., net.

John Bale, Sons and Danielsson, Ltd. (London).

Spring Catarrh of the Eyes. By H. Danvers, M D. Illustrated, with Three Plates. Pp. 60. Price 4s. net.

J. and A. Churchill (London).

Obstinate Hiccough. By L. F. B. Knuthsen, M.D.Edin. Pp. 169. Price 6s.

Eyre and Spottiswoode (London).

Reports and Papers on Bubonic Plague. By Dr. R. Bruce Low. With Introduction by the Medical Officer of the Local Government Board. Pp. 416. Price 4s. 1d.

Charles Griffin and Co., Ltd. (London).

The Work of the Digestive Glands. Lectures by Prof. J. P. Pawlow. Translated by W. H. Thompson, M.D., M.Ch., F.R.C.S.Eng. Illustrated. Pp. 196. Price 6s. net.

Adden, Best and Co. (London).

Hadden's Pocket Vocabulary of Medical Terms. By Henry Payne, M.D., &c. Third Edition. Revised and enlarged by Philip Cowen, M.D., and Herbert Davey, of the Middle Temple. Pp. 144.

H. K. Lewis (London).

Cancer of the Uterus. By Arthur H. N. Lewers, M.D.Lond., F.R C.P.Lond. With fifty-one Original Illustrations and three Coloured Plates. Pp. 328. Price 10s 6d. net.

Handbook of Surface Anatomy and Landmarks. By Bertram C. A. Windle, F.R.S., Sc.D., M.D., M.A. Third Edition. Pp. 141. Price 4s. net.

J B. Lippincott (Philadelphia and London).

A Text-book of the Science and Art of Obstetrics. By H.y J. Garrigues, A.M., M.B. With 504 Illustrations. Pp. 884. Price 25s.

Grant Richards (London).

Scientific Phrenology. By Bernard Hollander, M.D. With over 100 Illustrations. Pp. 307. Price 6s.

Elliot Stock (London).

Natural Food. By J. P. Sandlands, M.A., T.C.D., Vicar of Brigstock. Pp. 91. Price 1s.

Taylor and Francis (London).

Calendar of the Royal College of Surgeons of England. Pp. 332. Price 1s.

The death is announced of Mr. Edwin Haward, F.R.C.S., formerly of the Army Medical Service, in which capacity he went through the Crimean War and served at the base hospital at Scutari with Miss Florence Nightingale. He was in his 87th year.

Laboratory Notes.

BYNO-CASCADA.

Byno-cascada is the name given by Messrs. Allen and Hanbury to a combination of Bynin with Rhamnus purshiana and Rhamnus frangula. The bitter taste of the drug is masked by the vehicle without its having been necessary to tamper in any way with its composition, as in the so-called "tasteless" preparations of cascara. The addition of Rhamnus frangula is useful in that it tends to check the establishment of tolerance in respect of the laxative action. Moreover, the digestive and nutritive properties of Bynin are none the less valuable in this connection, and the combination represents a happy blend of digestive and laxative properties.

CADBURY'S MILK CHOCOLATE.

A combination of pure cocoa with the nutritive principles of milk furnishes an ideal food, and in the form in which it is presented by Messrs. Cadbury it is additionally attractive by reason of the perfection of preparation and delicate flavour of the product.

In this "milk chocolate" much of the cocoa butter is replaced by the more readily assimilable milk fat, and milk sugar (lactose) partly takes the place of ordinary cane sugar, thus avoiding the unduly sweet taste which would result from too large a proportion of the latter. The comparative non-liability of the former to undergo fermentative changes is another advantage attending the introduction of milk sugar.

The "milk chocolate," although it contains a very low percentage of moisture and is practically unalterable in any climate, does not give rise to the thirst which follows the ingestion of mixtures of cocoa and sugar. It is, moreover, an extremely nourishing and sustaining article of food which might well form part of "emergency rations."

PURGATIN.

We have received from Messrs. Knoll, Limited, samples of a new synthetical product possessed of laxative properties, to which (in accordance with an objectionable practice) the name of "Purgatin" has been given. It is derived from the oxyanthraquinones, the class of bodies to which belong the active constituents of cascara, rhubarb, senna, and other mild purgatives.

Its laxative action is mild or strong according to the dose employed. In five to ten grain doses the action is quite mild, whereas in doses of from twenty to thirty grains it is a drastic purgative. The best way to give the drug is in the form of tablets containing five grains, mixed with chocolate. It is tasteless, and gives rise to no colic or other inconvenient effect.

On general principles it is always preferable to make use of a definite chemical compound, and from this point of view, Purgatin, being an uniform crystalline substance, presents certain advantages.

It is important to note that it escapes in the urine in the form of anthrapurpurin, which gives a red colour to the urine, a point of which the patient should be informed beforehand.

TRIFERRIN.

This organic ferruginous salt, manufactured by the same firm, is a paranucleate of iron. It contains 22 per cent. of iron and 2·5 per cent. of organically-united phosphorus. It may reasonably be anticipated that iron and phosphorus in this organic combination are more readily assimilated than the inorganic salts still so largely used, and this assumption has been borne out by actual observation. The therapeutical effects of any ferruginous medication depend, of course, not so much on the quantity of iron administered as upon the proportion which undergoes absorption. From this point of view the therapeutical value of Triferrin is greatly in excess of all inorganic salts of iron. The dose is five grains, repeated several times a day, and it is put up in tablets mixed with chocolate for facility of administration.

The Earl of Dysart has contributed £100 to the funds of the National Anti-Vaccination League—a proof that inability to grasp the meaning of facts and figures is not confined to the uneducated classes.

Medical News.

Italian Trade Mark Infringers Punished.

We have received from Messrs. Burroughs Wellcome and Co. copies of the *jugements motivés* rendered in their favour in actions brought by them against several pharmaceutical firms in Italy for fraudulent use of their trade mark "Tabloid" and for imitation of their goods in such wise as to deceive the unwary customer. Imitation has been asserted to be the sincerest form of flattery, but when advantage is taken of such means to obtain the benefit of a popularity so painstakingly obtained and so deservedly retained by Messrs. Burroughs Wellcome and Co. it is a matter for satisfaction that the strong hand of the law should have been invoked to put a stop thereto. The lesson, no doubt, will not be thrown away, although it is not every firm which is prepared to enter upon prolonged and costly litigation to enforce its rights. We congratulate this enterprising firm on the fact that the appeals have been dismissed and the original verdict of the Milan Tribunal confirmed.

The Royal Academy of Medicine.

At the annual general meeting of the Royal Academy of Medicine last week the following officers were appointed:—President: Lombe Atthill. General Secretary: John B. Story. Secretary for Foreign Correspondence: Sir J. W. Moore. Medical Section—President: A. V. Macan. Council: J. B. Coleman, James Craig, W. R. Dawson, H. C. Drury, R. A. Hayes, T. P Kirkpatrick, J. Lumsden, J. O'Carroll, G. Peacocke, R. Travers Smith. Surgical Section—President: Lambert H. Ormsby. Council: Arthur Chance, J. P. Doyle, F. Conway Dwyer, G. Jameson Johnston. John Lentaigne, R. C. B. Maunsell, H. R. Swanzy, E. H. Taylor, W Taylor, R H. Woods. Obstetrical Section—President: W. J. Smyly. Council: Paul Carlton, R. H. Fleming, R. A. Flynn, J. H. Glenn, A. J. Horne, H. Jellett, J. L. Lane, A. J. Smith, E. Hastings Tweedy, T. H. Wilson. Pathological Section: President: E. J. M'Weeney. Council: A. H. Benson, J. B. Coleman, F. C. Crawley, H. E. Earl, J. O'Carroll, A. C. O'Sullivan, A. R. Parsons, J. A. Scott, F. C. Purser, A H. White. Section of Anatomy and Physiology—President: D. J. Cunningham. Council: A. Birmingham, D. J. Coffey, A. Fraser, E. H. Taylor, W. Taylor, W. H. Thompson. Section of State Medicine—President: Ninian Falkiner. Council: Sir C. Cameron, C.B., W. R. Dawson, F. C. Martley, Sir J. W. Moore, J. M. Redmond, W. A. Winter.

Testimonial to Dr. R. S. Allen.

Dr. R. S. Allen, of Belper, who was recently mulcted in £100 damages as the result of an action for libel brought against him by a former matron of the Belper Isolation Hospital, which, with costs, involved the loss of £600, was presented last week with a cheque for £200, contributed by friends, neighbours, and fellow-practitioners, as a tangible proof of sympathy with him under the trying circumstances.

Plague at San Francisco.

It is reported that bubonic plague is very prevalent in California, over 2,000 deaths having occurred since February in San Francisco alone The reports are somewhat conflicting, and it is difficult to avoid the suspicion that the real facts of the case are being kept from the public.

Death of Professor Eugen Hahn.

The death is announced of Professor Eugen Hahn, Chief of the Imperial Department of the Berlin Municipal Hospital at Friedrichshain. The deceased professor was one of the first surgeons to perform the operation for the radical cure of cancer of the larynx, and he also did much to advance the *technique* of operation on the intestines. He was born in 1841.

Cholera in Palestine.

Cholera has spread from Egypt into Palestine where it has already claimed about 500 victims, all natives. Railway traffic between Jerusalem and Jaffa has been arrested. There is a great lack of medical assistance, and, owing to the panic, even the necessaries of life are running short.

Small-pox in London.

Six fresh cases have been admitted to the hospitals of the Metropolitan Asylums Board during the fortnight ending on Thursday last. The total number of patients now under treatment is 24. At the corresponding date last year there were 258 small-pox patients under treatment.

Birmingham University Students Agitate.

The Students' Representative Council was re-elected last week, and a vigorous and wordy campaign was carried on, prior to the election, in favour of sending to the Council men pledged to repudiate the "grandmotherly legislation" which regulated indulgence in tobacco and prescribed "home work" as a remedy for idleness. The "opposition six" were duly elected, and the greatest excitement prevailed among the general body of students, who are unanimously in favour of the abolition of the Discipline Committee. An allocation in favour of order and attention to study delivered by the Colonial Secretary before he leaves for South Africa would perhaps assist the authorities in restraining these exuberant youths!

Irish Medical Schools' and Graduates' Association.

The autumn general meeting of the Association will be held at the Hotel Cecil, on Wednesday, November 26th, at 6.30 p.m. On the same evening the Association will dine in the Grand Hall of the Hotel Cecil at 7.15 p.m., when the chair will be taken by the President, Sir Philip Crampton-Smyly, M.D., F.R.C.S.I., Honorary Surgeon to the King. The Association will have the honour of entertaining the Commander-in-Chief, Field-Marshal the Right Honourable Earl Roberts, V.C., K.G., K.P., G.C.B., G.C.S.I., G.C.I.E., Countess Roberts, and their daughters.

Duke of York's School.

It has been decided that the appointment of medical officer of the Duke of York's School shall be converted into a post for an officer of the Royal Army Medical Corps on full pay, and Major J. C. Morgan, of that corps, will complete a term of three years in the appointment dating from January 1, 1901.

A Year's Bacteriological Work in India.

The report of the Imperial Bacteriologist for the past official year describes the chief work of the department for the year as the testing and production of rinderpest serum. The experiments were directed to improving its protective quality and perfecting the process of manufacture. The results obtained at Jacobabad, Madras, and Rangoon showed that the initial protective value of sera is materially diminished by exposure to high temperatures. Experiments have also been carried out in different localities to ascertain the strength of the doses required to secure protection in different breeds of cattle. Dr. Lingard is desired to prepare a special report on the results of his investigation into the best methods of obtaining a serum. The experiments as to anthrax are said to have been brought to a successful issue by the discovery of a protective serum, and researches were prosecuted into other animal diseases. There is an increasing demand for serum, the doses issued last year being very nearly double the number of those of the preceding one. A scheme recently sanctioned for enlarging the laboratory will, it is hoped, lead to the production of 100,000 doses of the serum per annum, while the plan for training veterinary assistants at the laboratory in the inoculation of cattle against rinderpest has been successful. It has been decided to discontinue the issue of fungus tubes for exterminating locusts, the results not having been successful in any of the provinces, and meanwhile investigations and experiments on the subject will be conducted in the Agricultural Department as well as by the bacteriologist.

A Medical Co-respondent.

Mr. Richard H. Darwent, L.R.C.P., L.R.C.S.Ed., of Hull, was one of the co-respondents in a suit for divorce brought by a local solicitor, and as no defence was offered a decree *nisi* was granted in favour of the petitioner. As the lady was a patient of Mr. Darwent's the matter will probably turn up again before another tribunal.

Nurse versus Doctor.

The action brought against Dr. Henry Vivian Bertram by Mrs. Margaret Ellen Ingle, a professional nurse, for alleged libel, has been settled without calling upon the jury for a verdict, one of them having disappeared as the result of the negotiations. The action arose from the defendant having remarked in a letter that the nurse had been guilty of violent treatment of her patient. This statement must be taken to have been without any foundation in fact, since the defendant agreed to withdraw the imputation. It were better for him that it had never been made.

No Substitutes.

A lady doctor at Battersea was recently directed by the coroner to carry out the post-mortem examination, but, diffident as to her ability to do the work satisfactorily, or unwilling to contaminate her hands with so foul a task, she called to her assistance a lady pathologist, an arrangement to which the coroner took exception, observing that he could only pay one fee, and he expected the examination to be made by the person to whom his order was addressed. With a little management the difficulty need never have arisen. Making an autopsy does not necessarily mean that the mechanical part of the work must be done by the witness. It is sufficient that he, or she, shall be in a position to testify to the facts of the case which, as an onlooker, he or she, would be quite in a position to do.

Death under Chloroform.

A man, aged 44, died under chloroform at Dr. Anderson's surgical hospital, Nottingham, when about to undergo an operation for the removal of an epitheliomatous growth of the lip. There was a good deal of excitement, the patient being extremely apprehensive of the anæsthetic, and, soon after, the breathing ceased. The usual verdict was returned.

Death from Septic Poisoning.

Mr. Roger Hughes Jones, M.R.C.S., L.R.C.P., of Penryn, Cornwall, scratched his hand when preparing a splint for an injured patient, and the wound became infected while attending to another patient suffering from erysipelas. He was thought to be convalescent, when he suddenly became collapsed and died. He was 47 years of age and had been ten years in practice at Penryn.

Heavy Sentence on the Bogus Doctor.

Mr. Herring, *alias* Hoffmeister, the brazen-faced rogue who audaciously assumed names and titles to which he had no right, and who by practising thereon contributed to the death of one of his patients, was tried for manslaughter at the Old Bailey last week, and was sentenced to five years' penal servitude. This is refreshing after the indulgence which, for some inscrutable reason, it is the custom to display towards this class of offender by magistrates and judges. This may *encourager les autres*.

Pass Lists.

Royal College of Physicians of Edinburgh Royal College of Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

The quarterly examinations of the above Board, held in Edinburgh, were concluded on the 30th ult., with the following results:—

First Examination, Four Years' Course.—Frederick Francis Middleweek passed the examination.

First Examination, Five Years' Course.—Of twenty-one candidates entered the following nine passed the examination: Archibald Randolph Fulton Douglas, John Peter Carroll, William Martin Ferguson, Henry James Gorrie, John Hugh Simpson, Thomas Boston Johnstone, William Church Mann, William Alexander Huston, Louis Nathaniel Robertson, and two passed in Elementary Biology and four in Chemistry.

Second Examination, Four Years' Course.—Of seven candidates entered the following five passed the examination: William Henry Curtis, William Hall, Randal Herley, A. M. S. Kelso, and William James Coppinger.

Second Examination, Five Years' Course.—Of twenty-five candidates entered the following ten passed the examination John William Pell, James Baillie, Archibald Cameron Ney, Henley John Byrne, James Taylor (with distinction), Claude Knight-Kennedy, William John Cogan, James Murphy, Reginalds Reynalds, John L. Power, and one in Anatomy and one in Physiology.

Third Examination, Five Years' Course.—Of twenty-eight candidates entered the following fifteen passed the examination: Evelyn Neville Lea Wilson, George Harrison, William Adams, John Arthur Denzil Rome, David Arnold Hastings, Evelyn Morris Franklin, Percy James Thomson, L.D.S., Dowlatram Gopaldas Advani, Vincent Paul Pereira, Stephen McCarthy, David Haig, William Millar Ramsay, Emile Reboul, Dora Mann, Margaret Lucy Tyler, and three in Materia Medica.

Final Examination.—Of eight candidates entered the following thirty-three passed the examination, and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. and S.G.: Ernest Joseph Addison, Milson Russen Rhodes, Anne Low Venters, Lilian Gertrude Simpson, Benjamin Isaac, Mary Edith Martin, Katharine Charis Davies, William Eugene Struthers, Hans Martinus Peries, Ethelbert Hearn, Andrew Paterson Walker, Trueman Edward Bishop, George Henry Wilkinson, Timothy Foley, Christopher Marley Cass, Charles Wilfred Coghlan, Elizabeth Mary Cardoze. Frederick Arnold Ritchie, Isa Charan, Nalini Nath Dey, Joseph Albertus Exton, Francis Audubon Gray, Robert Sutherland Mackintosh, Ryder Percival Nash, Kaikhushru Jehangir Bhamgara, Robert Gibson, Kottarathil Matthan Matthan, Andrew Smyth, John Coulter Warwick, James Macarthur, David Ahern, Lionel George Wickham, Norman Pigott Fairfax, and four passed in Medicine and Therapeutics, one in Surgery and Surgical Anatomy, twelve in Midwifery, and nine in Medical Jurisprudence.

The following gentlemen, having passed the requisite examinations, received the Diploma in Public Health of the above Board:—Thomas Lander Thomson, George Archibald Park Ross, Harry Moss Traquair, Charles William Somerville, Richard Hamilton, William John Barclay, Robert Paterson Heddle, Robert Brown Turnbull, and David Durran.

Royal College of Surgeons of Edinburgh.

At a meeting of the College held on Oct. 15th last, the following gentlemen, having passed the requisite examinations, were admitted Fellows of the College:—William Sloss, M.B., James Simpson Clayton, M.D., John Adamson Honey Duncan, M.D., Alexander Henry Edwards, David Gault, M.D., Robert George Henderson, M.B., William Edward Herbert, M.B., Harold Crossley Hildreth, L.R.C.S.E., Henry Cairns Lloyd, M.B., William Chisholm Macdonald, M.B., Alexander Morrison McIntosh, M.B., Arthur Augustus Pim, L.R.C.S.E., Robert George Riddell, M.B., Neil Robson, M.B., John Stuart Ross, M.B.

The Bathgate Prize, consisting of medal and medical books, founded by Colonel William Lorimer Bathgate, in memory of his late father, William McPhune Bathgate, F.R.C.S.E., Lecturer on Materia Medica in the Extra-academical School, for competition among students attending the extra-mural classes in Materia Medica, was awarded for the summer session to Mr. John Macmillan Campbell, 16, Scotland Street, Edinburgh.

University of Durham.

At the convocation holden on Tuesday, Oct. 21st, the following degrees were conferred, viz.:—Doctor in Medicine (for practitioners of fifteen years' standing): George Graham Hodgson, M.R.C.S., L.R.C.P., John Goodwin Shea, L.R.C.P., L.M, F.R.S.I, D.P.H. Bachelor in Medicine (M.B.): David Rees Roberts.

Conjoint Examinations in Ireland.

Second Professional (Part II.). Third Professional Examinations.—Candidates have passed these examinations as undernoted:—Second Professional (Part II.)—J. R. P. Allin, T. S. Blackwell, S. Close, G. H. Gallagher, W. Kelly, C. W. O'Keette, W. Sheahan.

Third Professional.—A. Four years.—G. T. O'Kelly.

B. Five years. Old Regulations.—W. H. Anderson, W. Cremin, M. Deeny, J. P. Falls, A. E. F. Hastings, T. J. Lloyd, F. J. Moore, J. J. McCounell, P. J. O'Farrell, W. Ormsby, C. F. P. Plunkett, M. C. Sage.

C. New Regulations.—F. W. Brunker, F. X. Costello, R. G. Griffin, P. Sampson.

Notices to Correspondents, Short Letters, &c

☛ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Mr. R. H.—The names of the Editorial Staff are not given to any but members of the profession, and then only for some very special reason.

Dr. S. E H.—The editor and translator of Professor Brouardel's work on "Death, and Sudden" is at present in Australia. A letter would find him at Semaphore, South Australia.

Dr. N. K.—You have omitted one very important item in your communication on which the point mainly rests. Please supply this, as we cannot venture on an expression of opinion.

AN INGENIOUS ADVERTISEMENT.

At the recent Grocery Exhibition the firm of Henri Nestlé attracted a good deal of interest by their exhibit of a Swiss chalet, the exact type of those with which travellers are familiar in the mountain pastures. The chalet was "furnished" with the requisite implements, not excepting the ubiquitous cow-bells, which are such an acoustically prominent feature of that country. These bells, which have a weird melody of their own, vary considerably in size, some of them approaching the dimensions and simulating the shape, of an upturned kettle, and they are attached to the animal by means of a broad, adorned collar. Outside the chalet were displayed decorated tiles representing pastoral subjects, with mottoes in Swiss patois, while the furniture inside was made of the usual Swiss carved wood. Altogether, it is difficult to imagine a more artistic and "taking" advertisement for the products with which the name of this firm is so intimately connected.

Dr. P.—We have taken note of the information you have been good enough to place at our disposal, and we propose to deal with more fully in our next.

Meetings of the Societies, &c.

LONDON.

Wednesday, November 5th.

Obstetrical Society of London (20, Hanover Square, W.).—8 p.m. Specimens will be shown by Mr. Bland-Sutton. Dr. Comyns-Berkeley. Dr. V. Bonney. Dr. R. H. Bell, and others. Paper:—Mr. W. S. Handley: On Paratubal Hæmatocele.

Thursday, November 6th.

Rontgen Society (20, Hanover Square, W.).—8.30 p.m. Opening Address:—Mr. H. Jackson (President).

Harveian Society of London (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Mr. A. Doran: Uterine Fibroids, considered from a Clinical and Surgical Standpoint. (Harveian Lecture.)

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—Impetigo: Dr. Colcott Fox.

North-East London Clinical Society (Tottenham Hospital, N.).—4 p.m. Clinical Cases.

Friday, November 7th.

West Kent Medico-Chirurgical Society (Royal Kent Dispensary. Greenwich Road, S.E.).—8.45 p.m. Paper:—Dr. J. H. Bryant: The Value of Blood Examination as an Aid to Diagnosis and Prognosis.

West London Medico-Chirurgical Society (Society's Rooms, West London Hospital).—8.30 p.m. Papers:—Mr. A. Doran: Choledochotomy in a Case of Chronic Jaundice with Cholangitis, Recovery.—Dr. F. J. McCann: Cases illustrating some of the Septic Complications met with during the Puerperal State.

Tuesday, November 11th.

Westminster Hospital (Broad Sanctuary, S.W.).—4.30 p.m.—Dr. Gossage: Medical Cases (Post-Graduate Clinical Demonstration).

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—Peripheral Neuritis: Dr. Judson Bury.

BELFAST:

Thursday, November 6th.

Royal College of Surgeons.—Council Meeting.

Friday, November 7th.

Royal College of Physicians.—Monthly Meeting, 4.30 p.m.

Monday, November 10th.

Royal College of Physicians.—Examination for Licence in Medicine commences.

Appointments.

Allport, Wilfrid, M.B., B.S.Lond., M.R.C.S., L.R.C.P., Honorary Ophthalmic Surgeon to the Stratford-on-Avon Hospital.

Banham, H. A. L., L.R.C.P., L.R.C.S.Edin., Medical Officer of Health to the Urban District Council of Worsborough.

Benthall, Winfred, M.B.Cantab., Honorary Consulting Physician to the Derbyshire Royal Infirmary.

Burnett, R., L.R.C.P.Lond., M.R.C.S., by the Birmingham Board of Guardians a District Medical Officer.

Farrant, Mark, Jun., M.R.C.S., L.R.C.P.L., D.P.H.Lond., Medical Officer and Public Vaccinator by the St. Thomas (Exeter) Board of Guardians.

Fennell, Charles H., M.A., M.D.Oxon, M.R.C.P.Lond., Assistant Medical Officer to Darenth Asylum.

Harmer, W. D., M.A., M.B.Cantab., F.R.C.S., Assistant Surgeon to the Metropolitan Hospital, Kingsland Road, N.E.

Little, E. Graham, B.A. Cape Univ., M.D., M.R.C.P Lond., M.R.C.S.Eng., Physician for Diseases of the Skin at St. Mary's Hospital, vice Mr. Malcolm Morris, who has been appointed Consulting Surgeon

Maguire, W. J., M.B., B.S., R.U.I., Surgeon to the North District of the Royal Irish Constabulary in Belfast.

Messiter, A. F., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon, under the Factory Act, for the Epworth District of the County of Lincoln.

Plumbe, S. T., M.D.Lond., M.R.C.S., Certifying Surgeon, under the Factory Act, for the Maidenhead District of the County of Berks and the Taplow District of the County of Bucks.

Swain, James, M.S., M.D.Lond., F.R.C.S.Eng., Honorary Surgeon to the Bristol Royal Infirmary.

Thornton, Frank B., M.B. B.S., Honorary Physician to the Derbyshire Royal Infirmary.

Vacancies.

Bristol Royal Infirmary.—House Physician. Salary £100 per annum, with apartments, board, and laundry. Applications to "Secretary and House Governor."

County Hospital York. Lady Superintendent. Salary £80 per annum, with board, apartments, and washing. Applications to Fredk. Neden, Secretary and Manager.

Down District Lunatic Asylum, Downpatrick.—Junior Male Assistant Medical Officer. Salary £100 per annum, with furnished apartments, board, washing, fuel, light, and attendance. Applications to the Resident Medical Superintendent.

London Hospital Medical College.—Assistant Demonstrator of Anatomy. Salary £90 per annum. Applications to Munro Scott, Warden, London Hospital Medical College, Mile End, E.

Mercy Hospital, Cork.—House Surgeon and Compounder. Salary £80 per annum, with board, apartments, and light. Immediate application to Hon. Secretary at the Hospital. (See advt.).

New Ross Union.—Medical Officer (temporary). Salary £4 4s. per week. Immediate application to P. A. Pope, Clerk of the Union. (See advt.)

Natal Government Laboratory.—Assistant. Salary £500 per annum. Applications to the Agent-General for Natal, 26, Victoria Street, London, S.W.

Royal Dental Hospital of London, Leicester Square.—Dental Superintendent. Honorarium £250 per annum. Applications to J. Francis Pink, Secretary.

Royal Orthopædic Hospital.—Resident House Surgeon and Registrar. Salary £100 per annum, with board and washing. Applications to Tate S. Mansford, Secretary, 15, Hanover Square, W.

Worcester County and City Asylum, Powick, near Worcester.—Assistant Medical Officer. Salary £140. Applications to Medical Superintendent.

Births.

Appleyard.—On Oct. 28th, at Cranbrook Road, Ilford, Essex, the wife of Walter R. Appleyard, M.R.C.S., L.S.A., of a daughter.

Elkington. On Oct 25th, at Newport, Salop, the wife of E. A. Elkington, M.B.Lond., of a daughter.

Fisher.—On Oct. 29th, at 83, Wimpole Street, Cavendish Square, London, the wife of J. Herbert Fisher, M.B., B S.Lond., F.R.C.S., of a son.

Madden.—On Oct. 8th, at Cairo, the wife of Frank Cole Madden, F.R.C.S., of a daughter.

Mack.—On Oct. 28th, at 95, Tredegar Road, Bow, E., the wife of H. Hamilton Mack, B.A., L.R.C.P., of a son.

Moon.—On Oct. 29th, at Broadstairs, the wife of Edward G. Moon, M.R.C.S., L.R.C.P., of a daughter.

Marriages.

Bryson—Wilkins.—On Oct. 1st, at St. Mary's Church, Calicut, Malabar, Madras Presidency, Captain Reginald Bryson, I.M.S., to Sybil Edith Gwendolyne, second daughter of Colonel Hackett Wilkins, I.M.S., and Mrs. Hackett Wilkins.

Cann—Langdale.—On Oct. 23rd, at the Parish Church, Uckfield, Thomas Ponsford Cann, M.D.Durh., of Newhaven, to Ellen Myra, elder daughter of Henry Marmaduke Langdale, surgeon, Uckfield.

Clarke—Stevens.—On Oct. 28th, at St. Bartholomew's, Horley, Samuel Arathoon Clarke, M.R.C.S., L.R.C.P., to Helena Mildred, youngest daughter of the late William Carr Stevens and Mrs. Stevens, of the Oaks, Horley.

Forman—Corbett.—On Oct. 25th, at Fence Houses, Co. Durham, Bernard Gilpin Forman, M.B., of Cloughton, Yorkshire, second son of the late J. Forman, Esq., W.S., Edinburgh, to Fanny Evelyn, third daughter of Vincent C. S. W. Corbett, Esq., Chilton Moor House, Co. Durham.

Wood—Blackbourn.—On Oct. 29th, at St. Matthew's, Bayswater, William Charrington Wood, M.D.Lond., F.R.S Eng., son of Louis H. Wood, of Dulwich, to Ethel Lucy, daughter of William Blackbourn, of Spring View, North Kensington.

Deaths.

Browne.—On Nov. 2nd, at his residence, Frith Lodge, Northwood, Herts, Lennox Browne, F.R.C.S.E., of Mansfield Street, Cavendish Square, London, Consulting Surgeon to the Central London Throat Hospital.

Miller.—On Oct. 25th, John Alexander Miller, M.R.C.S., L.K.Q.C.P.Irel., of Percy House, Percy Circus, W.C., and of Colaba, Herne Bay, Kent, aged 54.

Morrison. On Oct. 14th, W. Morrison, L.R.C.S.I., of Rathfriland, Co Down, at Belfast.

Shepherd.—On Oct. 28th, at Leeds, Timothy Arundel Jordan Shepherd, M.R.C.S., L.S.A., son of the late Robert Walter Mexborough Shepherd, of Plymouth, aged 44.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

Clinical Lecture
ON
FLAT-FOOT. (a)

By W. BRUCE CLARKE, M.A., M.B., F.R.C.S.,

Surgeon in Charge of the Orthopædic Department,
St. Bartholomew's Hospital.

By the term flat-foot I mean the giving way of the longitudinal arch of the foot, so that the foot is no longer arched, but is practically flat, or, in other words, that pathological condition in which the astragalus comes right down on the surface of the ground. There are many people who are called flat-footed who are not, in the ordinary pathological sense of the term, suffering from flat-foot; that is to say, one person has a foot with a low arch, and another person has a high arch, but both walk equally well. Flat-foot is divided into two great varieties—congenital and acquired. The congenital form is exceedingly rare, and in a very large number of instances is completely recovered from without any plan of treatment whatsoever. The term congenital flat-foot is not a good one, and I do not think we should speak of congenital flat-foot at all, except in the very rarest cases. Most of them are really instances of slight flat-foot occurring in early childhood. The acquired variety is very common; indeed, it is among the commonest of deformities. If you want to test for yourselves whether a foot is flat, one of the simplest ways is to get the patient to dip his foot into a basin of water and then walk across a piece of kamptulicon, and if one foot is flat and the other is not, you will notice a great difference in the prints of the two feet.

What are the bony deformities which accompany flat-foot? All sorts of statements will be found in books as to the deformities which are to be met with. The deformities will depend entirely on the length of time that the person with the flat-foot happens to have been in that condition. In the early stage the first thing that happens is the coming down of the astragalus. After that, particularly as most of the cases of flat-foot begin before growth is completed, there will very often be a thinning out of the scaphoid. Sometimes the scaphoid is pushed up on to the dorsum of the foot, and when the foot is thus deformed there is extra pressure upon the cuboid, and it gets narrowest at its outer extremity, so that in very extreme cases the base of the metatarsal bone of the little toe touches the os calcis. That is very rare, but it does occur in certain cases which are exceedingly well marked and of long duration. Later on there sometimes is ankylosis of some of the bones, occasionally a bony ankylosis between the os calcis and the cuboid, or possibly an ankylosis between the astragalus and the os calcis.

What are the causes of flat-foot? The ordinary causes are spoken of as rickets, rheumatism, weakness of various kinds, and traumatic causes. Rickets throws the weight of the body on to the wrong portion of the foot, and predisposes no doubt to the occurrence of flat-foot, and inasmuch as in rickets there is deficiency of lime salts in the bones, and the bones are softer, they are no doubt more prone to yield to strain. Rickets thus plays a certain part in the production of flat-foot. In my own experience I can only say that I do not think there is any cause which is so likely to produce flat-foot as rheumatism. In fact, I am certain that in the vast majority of cases rheumatism is practically at the bottom of all this trouble. I will relate to you the typical history of a case of flat-foot which is associated with rheumatism. The patient was a woman, and she said she had had various attacks of pain about her from time to time, which were obviously rheumatic pains. She had two attacks of ordinary rheumatic fever, and subsequently had had severe pain about different portions of her foot. What was more, she found that this pain was very much relieved from time to time by the same remedies which had relieved her pains in other parts of the body. So much is this the case that I almost, as a routine treatment, put such patients upon salicylate of soda, because I find it does a vast amount of good. I do not say that every case of flat-foot is benefited by salicylate of soda, but the majority of them are, and the pain of flat-foot almost entirely vanishes under treatment with salicylate of sodium or other analogous drugs. Under the head of rheumatism we must include gonorrhœal rheumatism. Gonorrhœal rheumatism is very rarely the cause of severe attacks of flat-foot, but, when it does occur as a cause, it produces some of the very worst and most intractable flat-feet.

It is laid down in the books that it is people with weak fibre, and so on, who suffer from flat-foot, and there are vague statements about weakness being the cause. Then we hear of people standing too long in the pursuit of their occupations, and so on. It always seems to me that there is but the slenderest evidence to show that weakness or lack of fibre, or whatever term is given, is, strictly speaking, a cause of flat-foot at all. I do not believe flat-foot is produced in ordinary weak people unless they have some definite disease in connection with their feet. I am certain that the vast majority who are supposed to be suffering from weakness merely, are actually suffering at the time when their flat-foot lesion begins from some form of rheumatic trouble. One of the best arguments against mere weakness producing flatness of the foot is that a person's foot may be found much weakened by tuberculous mischief, and yet flat-foot will not necessarily follow. A great many of the people who are supposed to be suffering from flat foot in consequence of weakness have either badly-fitting boots and shoes, or else have boots and shoes which let in a vast amount of water, and the consequence is that they suffer from rheumatism in the feet. One of the causes not sufficiently laid stress on is ordinary hallux valgus, or the painful great-toe joint of adolescence. I draw your attention to one fact in connection with flat-foot, namely, that nearly all such cases show considerable thickening about the great-toe joint. Let us think for one moment why hallux dolorosus produces flat-foot, and then we shall see why it is that various traumatic causes also produce flat-foot. In the ordinary way when walking one raises himself to a certain extent upon one's toes each time one moves forward. By so doing one exercises the muscles, ligaments, &c., of the soles of the feet, as well as the muscles of the leg. But if one has a painful great-toe joint one cannot do this because of the pain, and therefore one gets into a vicious way of walking. Instead of raising oneself up on tiptoe each step one takes, one walks with the foot stiff and with the feet turned out, a posture characteristic of the agricultural labourer when he follows the plough, wearing an exceedingly stiff pair of boots. If one goes on walking with one's foot absolutely stiff in that position it is certain, sooner or later, to result in a certain degree of flat-foot, because the tissues will have become weak from lack of exercise.

(a) Abstract of a Clinical Lecture delivered at St. Bartholomew's Hospital.

The most common among the traumatic causes of flat-foot are dislocations and injuries about the bones of the foot in the neighbourhood of the ankle-joint itself, including Potts' fracture. These cause flat-foot exactly in the same way as hallux valgus does. For a considerable length of time the patient who is suffering from these lesions is unable to use his foot in the ordinary way, and the foot is weakened by lack of exercise. That brings me to one of the indications for treatment which I may refer to here. Whenever a person has a foot so far damaged that he is unable to use that foot satisfactorily, he should always rest it moderately and take care of it until he can begin to resume his muscular action; otherwise he is very liable to get flat-foot resulting. The only symptom of flat-foot which is absolutely unequivocal is the pain; if a person complains of a certain amount of pain in or about the centre of the arch of the foot, and if that pain runs down into the great toe or into the heel, always be very suspicious of incipient flat-foot. Those pains are, in many instances, nothing more or less than the first onset of a slight attack of rheumatism. Patients come complaining of attacks of this nature, and if treated with salicylate of soda they go on for a considerable time without suffering any more pain, and may even be able to do without the special boot which has probably been ordered for them before I have seen them.

What is the course which the disease tends to take supposing that nothing whatever is done for the patient? In flat-foot there is absolutely no tendency whatever to spontaneous cure except in children, that is to say, this disease gradually progresses and gets worse and worse unless something is done for it. In the course of the disease, one of the most important things is the fact that the pain appears and disappears from time to time. A person may have exceedingly painful flat-foot, and may come for treatment. You may treat it by any of the various means I am referring to, and the patient may get better, and he may go on with the foot still flat, but not painful, for perhaps six, ten years, or more. And then suddenly there may be another attack of pain, and the foot will tend to get more flat still. At these stages of exacerbation, I do not think you will have much difficulty in satisfying yourselves that, as a general rule, these attacks are due to rheumatism, which comes on at different periods of the patient's existence. Sometimes you will notice that a patient increases in weight, and consequently puts a considerably increased weight upon a foot which is already weakened. In some instances that explains why it is that the foot gets worse from time to time, and better again at other times. And I think I may go so far as to say this, that every person who increases inordinately in weight sooner or later suffers with his feet in one way or another. I am often saying that one of the most important diseases which we have to treat, and which we ought to regard as a disease, is obesity. I do not think we should allow anybody to get beyond a certain stage of fatness without treating him for it. To put five, six, seven, or eight stone more on the feet than they were intended to bear is one of the most fertile causes of an increasing degree of flat-foot that can be imagined.

What are the treatments which we ought to adopt? What can we do for flat-foot in its different stages? The first thing to remember is the course of the disease. The treatment which is applicable to one stage of the disease is absolutely inapplicable at another. So long as a patient is suffering merely from pain, I am in the habit of describing it as merely a tendency to flat-foot. At this stage, when there is only a tendency to the condition, and it has not yet been established, a cure can nearly always be effected by giving salicylates, because the majority of cases at that stage are nothing more nor less than rheumatism. In other words, there is rheumatism in the fibrous tissue of the sole of the foot, and these tissues are becoming gradually softened; the weight of the body acting on these softened tissues causes the arch of the foot to give way.

The next important thing is to train the muscles. If you ask people what sort of treatment they are going to adopt for flat-foot, they will say, in most instances, "muscular exercises." Muscular exercises are all very well, but they must not be ordered indiscriminately. The patient's foot must be sufficiently free from pain to enable him to perform exercises. But freedom from pain is not the only condition which is necessary for the performance of the exercises. A comparatively painless foot may be ankylosed in a certain position, and, if this is the case, exercises will be of no avail whatever until the ankylosed joints are broken down. It must be brought back into the position in which it is capable of moving. Treat any dislocation which has taken place here much in the same way as you treat any other dislocation: try to reduce it. Having restored the arch of the foot there will be some difficulty in keeping the foot in that position to which it has been unaccustomed for so long. In other words, having more or less restored the arch of the foot, it must be kept in position by putting it in plaster for five or six weeks, or longer. At the end of that time the patient will probably be able to perform certain exercises. The exercises which they ought to perform are, first of all to raise themselves up on tiptoe four or five times night and morning, and then to roll the feet from the outside edge to the inner backwards and forwards, as people do when skating. If they can perform these exercises, I am sure that, provided they get no further rheumatism, they may look forward to, I will not say in all instances to cure of their flat-foot; but, at any rate, to a cure of the symptoms which make this flat-foot uncomfortable to them. If, on the other hand, the patients cannot perform those exercises, in all probability the bones have been much more deformed in the way in which I have referred to earlier in this lecture, and there may be some synostosis between the bones. The result of this is that such patients are unable to get their feet into anything like a natural position. Under those circumstances it is often customary to order supports for them. Personally I am not very fond of supports. Although I do not mean to say that there are never feet which require instruments of various kinds, I say those instruments should be used as rarely as possible. One of the instruments used is sometimes spoken of as a flat-foot boot, which may be of the first, or the second, or the third degree, as it is called. Sometimes we put into the boots what are called valgus pads, which may be composed of horsehair, or rubber, or leather, or glycerine. Glycerine I do not advise, because it may burst in the boot, and that would not be very comfortable. We also have, for extreme cases of flat-foot, a form of boot, in which an iron is fixed to the outside of the boot, and a valgus T-strap, which pulls the foot up in this direction. That strap is affixed, directly or indirectly, to the outside iron, and sometimes to a ring that goes round the calf as well. These are the usual methods of instrumental treatment which we adopt for flat-foot. Sometimes we use steel soles inside the boot. An objection to treatment by all these instruments is that the patients often complain that the pressure on the under surface of the sole of the foot is so great that they cannot stand the instrument.

Although definite surgical operation is rarely called for, there are a certain number of cases in which it is absolutely essential. There are various operations:—One consists in removing a wedge-shaped piece of bone from the inside of the foot, and so rectifying the deformity by giving the patient a more or less fixed arch to the foot. In the cases upon which we operate the arch of the foot has long been immovable, and therefore by the operation we are not, as is often said, taking away movable joints, but we are giving our patient a foot which he can readily walk upon, and which is fixed in proper position in place of one which is fixed and painful, and on which he cannot walk. Amputation may have to be performed in certain instances.

The treatment from which you can hope for the best results is the one which I speak of as muscular exercises, but I ask you to bear in mind that the matter must be looked at from a sensible point of view. You must look at every foot for yourself, and satisfy yourself that the patient for whom you order exercises is able to perform them. Each patient must be carefully instructed as to the particular exercises he must perform.

THE TREATMENT OF CANCER BY PHOTO-THERAPY. (a)

By DAWSON F. D. TURNER, F.R.C.P. Ed.

In a paper read in 1894 the author referred to the treatment of goitre in India by the red iodide of mercury ointment and the rays of the sun, and suggested in explanation that the effect produced was due to the radial heat rays. The results of this treatment were extraordinary; 60,000 natives were treated, and a cure was almost always effected. A few years ago Finsen, who had been experimenting with the red end of the spectrum on small-pox, turned the attention of the medical world to the curative effect of the other end of the spectrum—the blue, violet, and ultra-violet rays. These forms of radiation do not differ in any physical respect from ordinary light. The red rays are longer, produce the sensation of heat, and do not affect the ordinary sensitive silver salts; the violet rays are shorter, powerfully actinic, and scarcely affect the temperature sense; on the other hand, while the red rays penetrate the epithelium and softer structures, the violet rays have little penetrative power and are absorbed and stopped by the blood. What the Röntgen rays are nobody yet knows, but they do not behave like ordinary light rays, opacity to them being a question of density, all light bodies being transparent. Thus they pass through the skin and soft tissues with great facility, but throw shadows of the bones. They appear to have no bactericidal effect; while ultra-violet light has a marked action in destroying bacteria. The pathological effects of the rays are also different. The actinic rays produce within eighteen hours a transitory erythema consisting in an inflammatory dilation of the vessels with infiltration and œdema. In the case of lupus Macleod found that the rays caused a degeneration of the granulomatous tissue and the destruction of its vitality, but that in the case of healthy tissue their effect was negligible. The Röntgen rays produce more profound vascular and trophic changes, particularly if soft tubes be used, but this effect is cumulative and requires time for its establishment; its appearance may even be delayed for a fortnight or more. The skin becomes hyperæmic and of a deep reddish-violet hue; purulent dermatitis may follow, attended sometimes by intractable ulcers, and even by cancer. The minute changes consist in vacuolation of the endothelium of the blood-vessels, with thickening of the intima leading to thrombosis, in disintegration of the elastic tissue, and in disappearance of the hair follicles and sebaceous glands. The writer ventures to suggest the following theory as regards the action of these rays in cancer. As they will destroy, if pushed, the healthy skin by a species of burn, it is probable that they will more easily and rapidly destroy the lowly-organised malignant growth, and our aim should therefore be so to time the exposures as to disintegrate the abnormal without damage to the normal. The proper selection of a tube is most important: for superficial growths with ulceration a very soft tube should be chosen; if the skin be intact a more penetrating tube; while for internal growths a tube yielding still more penetrating rays should be used. He had only employed the Finsen light in the treatment of cancer for subcutaneous nodules where the skin was intact and the necessary pressure could be borne. In one such case the cancerous nodules disappeared as if by magic.

The following conclusions as to treatment might be stated:—

1. External cancer before ulceration may be treated by X-rays or Finsen light, preferably the latter.
2. After ulceration X-rays should be used.
3. For internal cancer only the X-rays are available.
4. Clinical results of the treatment are to remove or diminish pain, to loosen adhesions, to cause ulcerating and sloughing surfaces to take on healthy action and to diminish in size by the ingrowth of the epithelium from the edge, and occasionally to dissipate cancerous or sarcomatous tumours.

Details of eighteen cases of inoperable cancer were then given; nine affecting breast, two the tongue, and one of each of the following:—Penis, cervix, rectum, scalp, inguinal glands, larynx, neck. All but these showed improvement, the breast cases being the most successful and the tongue cases least so. Recurrence was usual, and no definite cure had been seen; the treatment was a race with the disease, and a stage could be arrived at in which one or two exposures per week will suffice to keep the disease in abeyance and to remove any distressing symptoms.

(a) Abstract of paper read before the Edinburgh Medico-Chirurgical Society, November, 1902.

PATHOGENIC VARIETIES OF BACILLUS COLI IN ICE-CREAMS. (a)

By PROFESSOR E. KLEIN.

THE *role* of the group of Bacillus coli in the causation of disease is becoming daily more recognised, particularly in reference to the presence of these microbes in foodstuffs, which thereby become endowed with the power of causing acute gastro-enteritis in the consumer. It has been proved that the particular variety of B. coli known as the Gaertner bacillus is the cause of acute gastro-enteritis in a number of outbreaks of this disease induced by the ingestion of certain meat foodstuffs. But it would not be justifiable to ascribe all occurrences of disease of this character to this particular variety, namely, the Gaertner bacillus, nor would it be without a tendency to confusion to regard all microbes as belonging to the group of Gaertner bacillus which in rodents are capable of causing acute gastro-enteritis as part of a general hæmorrhagic septicæmia. In my experience there exist various microbes of the coli group, but which do not belong to the Gaertner group, which can cause, and moreover which have caused, acute gastro-enteritis, and I am fully in accord with most bacteriologists who have experience in this matter by excluding from the Gaertner group such microbic species as the bacillus of fowl cholera, the bacillus of swine plague, and the bacillus of swine fever, although these microbes are capable on ingestion of producing in rodents, in a considerable percentage of the experimental animals, acute gastro-enteritis as part of a general hæmorrhagic septicæmia. In respect of microbes which certainly do belong to the Gaertner group, and which have caused acute enteritis in human beings, I may be permitted to refer to two notable outbreaks of meat poisoning which have been described in the Reports of the Medical Officer of the Local Government Board. The first—the Carlisle outbreak—is described in the Report for 1889. Here it was pork and gravy stock which had been at fault. From the same establishment and from the same stock from which the poisonous pies had been derived pork and gravy stock proved capable of causing, by feeding of mice, acute gastro-enteritis and death in a large percentage of the animals. From these animals a microbe was isolated which, on inoculation and by feeding of further animals, proved highly virulent. This microbe certainly did not belong to the Gaertner group, since its growth caused slow liquefaction of gelatine. Another outbreak—the Portsmouth meat-pie poisoning—was published in the Report of the Medical Officer of the Local Government Board in 1890, p. 249. In this outbreak the poisonous nature of the meat-pie was fully confirmed by experiments of feeding mice with the meat-pie; the microbe isolated both from the pie and the experimental animals was a virulent B. coli, which certainly does not belong to the Gaertner group. Now it may not be unnecessary if I here restate the characters which bacteriologists assign to the variety of B. coli known and considered as the "Gaertner bacillus." The Gaertner bacillus in respect of the nature and aspect of the colonies in the plate, in streak, stab, and shake culture in gelatine and agar, in its growth in carbolised broth, in its general morphology, in its inability to stain by Gram, in its giving positive neutral red test, admittedly belongs to the group of B. coli, but it differs from the typical B. coli communis in the following respects: B. Gaertner does not clot milk; B. Gaertner forms alkali (litmus milk and litmus broth becoming gradually blue); B. Gaertner ferments produces CO_2 gas from glucose like B. coli communis, but B. Gaertner does not ferment lactose (B. coli does so); B. Gaertner does not form indol in broth; B. Gaertner is multiflagellated similar to, though not identical with, the Bacillus typhosus. There are, therefore, a number of characters, morphological and cultural, by which the B. Gaertner is readily distinguished. To this must be added also that B. Gaertner is virulent to rodents subcutaneously injected even in minute doses, and in larger doses it is capable sometimes of causing general infection also by ingestion. On the other hand a microbe which produces acid in cultivation, which curdles milk, which ferments both glucose and lactose, which is not multiflagellated, which produces indol in broth culture, cannot claim to be considered as B. Gaertner, but must be content with a place in the group of B. coli communis. Now, a microbic species of this kind, but possessing highly virulent character, I have isolated from certain samples of ice-creams, which I shall describe in detail presently. I may at once say that the culture of this microbe caused, on inoculation of minute doses into rodents, general hæmorrhagic septicæmia, including acute gastro-enteritis and peritonitis, and death within twenty-four to forty hours. Injection of culture caused illness of the majority and death of a proportion of the animals experimented on. On *post-mortem* examination of the latter acute and severe gastro enteritis and peritonitis were found, the whole of the small intestine being deeply congested, relaxed, filled and distended by sanguineous masses. I show under the microscope a specimen of the sanguineous exudation filling the subcutaneous and muscular tissues of the abdomen and chest of an animal that died within twenty-four hours after subcutaneous injection of a minute quantity of a particular sample of ice-cream. Culture by plates proved that the bacilli which you see almost densely filling the exudation belong to one and the same species; and further inoculations with the exudation (one or two drops for a half-grown guinea-pig) caused the same fatal disease with the same distribution of the microbe in the dead body. Not only were the subcutaneous tissue full of the sanguineous exudation crowded with the bacilli, but also the lungs, the pleural and pericardial cavities, the peritoneum and the intestines. A second specimen shown under the microscope is a stained film of peritoneal exudation of a guinea-pig which had died within twenty-four hours from acute gastro-enteritis after feeding with a gelatine culture of the bacillus. Plate culture made with this peritoneal exudation proved the bacilli to belong to one and the same species, namely, the species used for the feeding. The microbe in question belongs undoubtedly to the coli group; in morphological and cultural respects it is closely related to the typical Bacillus coli communis, from which it differs in certain respects. It is more motile in the hanging drop than the B. coli communis, although it possesses only 1 to 5 flagella. Like B. coli it ferments glucose and lactose; it curdles milk, produces acid, and doubtful or slight indol (?); in broth culture it gives positive results in neutral red test. On potato it forms a colourless thin film, and, as already mentioned, is highly pathogenic, both by subcutaneous injection of small doses and also by ingestion of gelatine culture. I produce here cultures of B. coli communis, of B. Gaertner, and of our pathogenic ice-cream bacillus, to show their chief points of cultural differences and resemblances. The sources from which the above microbe was obtained were, as mentioned already, samples of ice-creams. Dr. Collingridge, the Medical Officer of Health for the City of London, had been informed by the Medical Officer of the General Post Office that two telegraph boys (afterwards it appeared that altogether thirteen suspicious cases had come to the notice of the Medical Officer of the General Post Office) had been taken ill with what appeared to be acute gastro-enteritis, believed to be due to poisoning by ice-cream bought at an Italian shop in Aldersgate Street. Dr. Collingridge therefore sent to me for analysis and experiment samples of ice cream that were bought at these shops. Both samples were, indeed, found to contain poisonous properties, inasmuch as the injection of ½ c.cm. to 1 c.cm. subcutaneously into half-grown to full-grown guinea-pigs caused extensive inflammation and gangrene of the subcutaneous and muscular tissues, as also intensive inflammation of the peritoneum, of the stomach and intestine. In the exudation anaerobic microbes, as also, and in great abundance, the highly-virulent variety of B. coli, were met with. On further transmission by subcutaneous injection of a drop or two of the sanguineous exudation this particular species was obtained almost in pure culture. Not only in those samples but in several other samples of ice-cream sent to me for analysis by Dr. Collingridge was this or some very similar highly virulent variety of B. coli met with, and I would particularly refer to a number of samples taken at different dates from different shops, but all supplied by one and the same maker. They all proved of the same poisonous nature, and this character persisted until the maker abandoned the highly insanitary conditions then prevailing on his premises, and complied with the suggestions and requirements of the medical officer. As soon as this change took place the ice-creams became harmless; injection of 1 c.cm. of the material into small guinea-pigs failed to exert any pathogenic action. The materials from which the ices were made were themselves found to be harmless, and therefore the poisonous nature of the ice-creams must have been due to admixtures by the extremely insanitary local conditions under which the ices were made, the uncleanliness of the manipulating persons, and the storing and keeping of the "stock" of ice-creams in filthy places. This latter malpractice is particularly favoured by some makers, namely, the ingredients are mixed so as to form a common stock; this is used for freezing in such quantities only as are likely to be required for sale that day. The rest is kept in a dirty place for future freezing and sale. No better confirmation, I think, of the correctness of the recently passed law (as regards the manufacture and sale of ice-creams) could be desired.

(a) Abstract of paper read before the Pathological Society.

STANDARDS FOR DRUGS. *(a)*

By H. WHIPPELL GADD, F.C.S.

The study of drugs is not a popular one: despite the proverbial love of the druggist for water, it is essentially a dry subject. Moreover, the tendency of modern medicine is to rely less upon physic, and more upon physical conditions, to see that the public health is maintained by sanitary surroundings, rather than to attempt the relief of the diseases of the public by drastic dosing. "Throw physic to the dogs" would be a popular motto for this Congress, if we had not learnt to be merciful to the brute creation. On the other hand, there never was a time when so many new drugs were being introduced, and the spread of education, far from suppressing quackery, seems but to have opened new avenues for the exploiting of nostrums.

A perusal of the public press makes one wonder why any disease remains, when all can be cured for thirteenpence halfpenny, but we are only concerned with what may be called "legitimate drugs," that is to say, remedies of known origin and proved potency. And it is for such that standards are necessary, if to their potency is to be added the equally essential property of uniformity.

"*Caveat emptor*," which to a great extent applies to foods, has little meaning for drugs. Every man (and still more every woman) thinks himself able to judge the quality of the food in the market, but the value of drugs cannot be assayed by "the man in the street." His experience is usually limited to shutting his eyes, and obscuring his senses of taste and smell, whilst the physic makes its nauseous but necessary passage down his throat.

Drugs may be roughly divided into three classes:—(1) Vegetable products and their preparations. (2) Animal products. (3) Substances of definite chemical composition.

1. From the earliest times, man has sought relief from the ills to which his flesh is heir in the herbs of the field, and to-day we use all kinds of vegetable products —roots, barks, stems, flowers, fruits, seeds, gums, resins, and many others. Many of these have been selected empirically, but their efficacy having been proved, it is important that there should be as little variance as possible in commercial samples.

The point of first importance is identification: Plants closely allied botanically often differ widely in their therapeutic effects. A drug having been found useful, a demand is created, and at first high prices are obtained: ignorant or dishonest collectors send large supplies of the true or any allied species to the market the drug becomes discredited and prices drop; the consequence being that it is no longer remunerative to collect the genuine article, and it ceases to be obtainable.

That this is no fancy picture can be testified by anyone who in recent years has had occasion to buy (or try to buy) jaborandi leaves or pareira roots, or strophanthus seeds. It requires a botanical expert to detect the difference between the leaves of pilocarpus jaborandi and some allied species; yet some of the latter are almost destitute of the alkaloid pilocarpine, and their therapeutic properties are probably equally poor. The literature of strophanthus is voluminous; yet to-day most of us have to trust to a somewhat unsatisfactory colour reaction to prove the identity of the commercial samples which come into our hands. Why cannot the very active authorities of the City of London for once take a vacation from their congenial work of buying pennyworths of harmless if necessary drugs from hucksters, and devote their energies to obtaining samples of the potent drugs offered in quantity in the auction rooms of their city?

Drugs having been identified, should if possible be assayed: for the mode of collection, the conditions of cultivation, the influence of climate and many other factors tend to produce variations of strength.

To take a simple example, jalap root, which depends for its activity on its resin, has been found to contain this constituent in quantities varying from 5 to 20 per cent. One can almost believe the story which is told of a Professor of Materia Medica in an Irish School of Medicine. "Gentlemen," he is reported to have said, "These are the properties of jalap, but I must warn you that the jalap supplied to this hospital is astringent in its action." Opium, again, varies much in strength, and is assayed for its morphine content, cinchona for its total alkaloids and percentage of quinine and cinchonidine, nux vomica for its strychnine (not, I trust, by the unmodified pharmacopœial method, which gives results varying with the taste and fancy of the analyst), ipecacuanha and belladonna for their alkaloidal strength.

When the active principle of a drug is unknown or cannot readily be assayed, its value can sometimes be approximately estimated by treating it with solvents, by incinerating and noting the yield of ash, and by applying other simple tests. For example, the pharmacopœia requires that gum benzoin should be "almost entirely soluble in alcohol 90 per cent.," whereas commercial samples often contain as much as 30 per cent. insoluble matter, chiefly bark, which is harmless but inert.

Obviously, if a gum cannot be obtained which answers the official test in making preparations, such as "Friar's Balsam," allowance should be made for the foreign element, a proportionately larger amount of commercial gum being used than would be required if the pure product could be obtained. Again in the case in the now rarely used drug assafœtida, the ash figure is a fair criterion of quality. Commercial samples on incineration often leave a residue equal to 50-60 per cent. of their weight, consisting as they do of about half gum and half stones.

From vegetable drugs, we naturally pass to their preparations, "Galenicals" as they are called, after the Greek physician, who is said to have introduced them. These are valued in much the same way as are the crude drugs. Thus laudanum is standardised to a percentage of morphine, the preparations of belladonna and ipecacuanha to total alkaloidal strength, tincture of nux vomica to its strychnine content, tincture of jalap to a percentage of resin, and others in like manner. Again, as with the crude drugs, when accurate analysis is difficult or impracticable, simpler tests may be used, such as specific gravity, alcoholic strength, and percentage of dissolved matter, or extractive.

With regard to these latter, however, a wide range must be allowed in fixing standards, for even genuine

---

(*a*) Abstract of paper read at the Exeter Congress of the Royal Institute of Public Health.

samples show very considerable variation. Thus, samples of tincture of capsicum have been found to contain a percentage of extractive, varying from 0·7 to 1·5 per cent., tincture of gelsemium may yield from 0·9 to 2 per cent., and tincture of strophanthus from 0·35 to 0·75 per cent. Solid extracts, which should have a definite relation to the crude drugs, from which they are prepared, may be approximately standardised by directing that they be concentrated to a given weight, instead of to "a soft extract," "to a suitable consistence for making pills," &c.

2. Chemical substances having definite composition do not require the same treatment as vegetable products; but seeing that absolute purity is seldom attainable, sometimes undesirable, and usually incompatible with commercial conditions, standards are necessary to fix limits for impurities. Impurities may be inert substances, acting simply as diluents, or they may be actively injurious, as, for example, arsenium, lead, and copper. Each salt used in medicine should be required to pass such tests as will ensure its freedom from injurious substances in appreciable quantities, and from harmless impurities in quantities that will materially impair the efficacy of the medicine.

3. Animal products, such as antitoxins, are, of course, standardised by physiological tests, a method of assay which in this country can be used to a very limited extent, although drugs thus tested are fully admitted from other lands.

I have tried to show that standards are needed for drugs, it remains to be considered:

(1) How they may be fixed.

(2) How they may be maintained.

How may they be fixed?

The British Pharmacopœia is in some sense the official standard, that is to say, it is the physician's prescription book, which the pharmacist is bound to use, but it was never meant to be set up as an authority under the Sale of Food and Drugs Acts, and if it is to be used as such it must be compiled with greater care and interpreted in the light of common sense. For example, because carbonate of sodium is an official salt, it need not be held that every lump of washing soda which the laundress purchases must correspond to the formula $Na_2 Co_3$, 10 H_2O, "only that and nothing more."

Processes for the assay of important drugs, such as nux vomica, must not be inserted without trial. It is no answer to criticism to say that further research is needed. Research must precede publication or disaster will follow it. If pharmaceutical products are to be judged by the Pharmacopœia, pharmacists must assist in its compilation, as they do in every (other) civilised country.

Again, if standards are to be fixed, they must be based not on museum specimens, but on the best obtainable commercial samples. It has been wisely said that "the best is often the enemy of the good." Too high a standard may result in a limited supply of the finest specimens at prohibitive prices, with indefinite and unguaranteed products for general use. Just as a thoughtful legislature has provided that if a man be unable to attain the educational standard required by the Pharmacy Act, he may contract himself outside its scope by joining with six other unqualified persons and becoming a limited company; so, if the standard for a drug be unattainable, it may result in compounds being sold which are not amenable to any restrictions.

It cannot too often be reiterated that in dealing with medicines uniform mediocrity is preferable to alternate strength and weakness.

Lastly, how may drug standards be maintained?

First and foremost by education of druggists. Skilled collectors, skilled manufacturers, skilled distributors, skilled dispensers, are the best guarantee of satisfactory products. We do not like indifferent cooks. We dare not trust incompetent chemists. And it follows that there must be adequate remuneration. Charles Kingsley led a crusade against "cheap clothes and nasty"; we want a new prophet to preach that cheap drugs are nasty. The ordinary principles of commercial competition are not applicable to the weapons with which physicians fight disease. Only in the last resort should standards be maintained by penal proceedings.

For the wilful adulterator, the miscreant who, for the sake of a little profit, would jeopardise the sick man's chance of life, the laws of England provide no adequate penalty (hanging being a merciful form of death). Carelessness in important matters is only a minor form of crime; but technical breaches of the law should not be treated as criminal offences. For example, when such a rigid Government department as the Excise has decided that certain liniments, being absolutely unpotable, may be made with methylated spirit, it is obviously unfair that tradesmen should be prosecuted under the Food and Drugs Acts for selling such. Again, when not for the sake of extra profit, but for the safety of the public, mercurial ointment is diluted before being sold, a penalty is unsuitable, when praise only is due.

The standardisation of drugs is a wide subject, which can be viewed from many points, the medical, the analytical, the pharmaceutical, the commercial, but more important than any of these is the question "How can drugs be standardised for the benefit of the Public Health?" And that must be my excuse for presenting these somewhat discursive remarks to this important congress.

Clinical Records.

TWO CASES OF NEURASTHENIA TREATED BY OPERATION.

By J. Stuart Nairne, F.R.C.S.,
Senior Surgeon, Glasgow Samaritan Hospital for Women.

This patient, married four years, had no children. She was a well-educated woman, having travelled much. She had never felt very well since her marriage, although neither she nor her husband attributed her ill-health to the marriage.

She was strongly marked with small-pox, but, notwithstanding, had a considerable share of good looks, of which she was not unaware; and perhaps there may have been an idea in some minds that part of her trouble consisted in realising she might have been still better looking if she had not been marked with the small-pox. Be this as it may, she was of variable temperament, now up, now down, happy and miserable and morbid by turns. Indefinite pains troubled her, pains that she could by no means locate, and other physical pains and aches troubled her definitely enough in the usual sites of loins, flanks, back, spine, and head. She suffered from dysmenorrhœa, and the menstrual flow was clotted, dark and tarry, with sometimes a smell.

Her husband was an educated gentleman who dabbled in hypnotism, Braidism, and spiritualism. He told me, and she told me, that he had put her frequently into the mesmeric sleep, specially when she was very ill. He had sent her off into this sleep and given her rest when nothing she did did her any good. They were both anxious that something radical should be done—anything so that there was a prospect of definitely and permanently curing her.

I examined her; found the pelvic conditions sufficient to justify me in saying that I believed a laparotomy, with liberty to remove the appendages if I thought it necessary, would probably be a permanent cure. Both parties said they had had such an idea in their minds, and were prepared to abide by my decision. The gentleman suggested that instead of the ordinary anæsthetic he should put his wife into the mesmeric sleep. I consented with a considerable degree of alacrity, for, although I had years before done some minor operations under the hypnotic condition, I had never had the opportunity of performing a major operation under the same condition. This being agreed to, I thereupon asked him at the earliest opportunity to exhibit his power over her and send her to sleep, in order that I might judge whether the sleep would be deep enough for my purpose. I am sorry to add that the lady was never put to sleep. His power had gone, and try again and again as he might, nothing came of it. The lady remained wide awake.

Nevertheless the operation was still determined on, and we overcame the little difficulty with the usual anæsthetic.

At the operation I found the left ovary grossly affected with cystic disease, and the right not visible. The uterus was rigid, but not very markedly so. Under these circumstances I gave her the benefit of the doubt an removed only the left appendages. She made an easy recovery, and was well when she left the Home. So long as she remained in Scotland she was well, but when in the course of a few months she had to leave for India my repentance began. It was, I am sure, misjudged mercy—a fallacious conservatism; for she slowly relapsed into her former condition, and I heard from her last year as desirous to return and have a complete removal of the other appendage. I believe she is right, and I believe also that, granting she recovers from the operation, she will be quite rid of all her troubles thereafter. I do not reckon this case as a success, but as one that has many plain lessons on its face.

The second case is that of Mrs. M., a married woman, æt. 45. Whatever shadow of a doubt I had had with regard to the diagnosis of neurasthenia and hysteria in association with the uterine condition was dissipated by my study and treatment of this case.

Mrs. M. had been under treatment for a long time by a most intelligent and well-educated practitioner. She herself was a woman of outstanding simplicity of character—full of sense as well as sensibility. None of us were in any special hurry to anticipate trouble, and so long as we could keep her going on reasonably we did not consider it was wise to perform or even suggest an operation. By and by, however, the condition became unbearable, and her distresses increased every day. She suffered constantly from pains and aches, fears by day and terrors by night, only now and again snatching an easy hour of peace of mind and body when her pains ceased. At last an operation was suggested, and on June 29th, 1899, she writes :—"You don't know how an operation haunts me, and consequently unnerves me. For the last two days I have had constantly that horrid dull pain in my left side, not the bowel you know. My headache is gone. I am sleeping well at night and don't feel so tired through the day, because I am taking more rest." The operation was done and the conditions were found exactly as I anticipated. The ovaries and tubes were distinctly inflamed and cystic, but not more so than one might reasonably expect in a long standing case of pelvic disease, and certainly not beyond what one would expect to yield to ordinary medical treatment, but the uterus itself, enlarged with fibroid degeneration, stood erect in the pelvis, and was the prominent sign immediately on opening the abdomen.

She was upset and hysterical for several days after the operation, but soon settled down. Her recovery was uninterrupted, and has remained permanent. From being a wasted and anxious creature she wrote on December 13th, 1899, that she felt much stronger, although she still had fits of nerves and sleeplessness, but that was improving. On March 11th, 1900, she wrote, "I am getting fine and well, rosy plump cheeks. I weigh nearly nine stone. You would not recognise me as the fretful patient you had in St. Margaret's Home."

TWO CASES OF MYCOSIS FUNGOIDES. (*a*)

By W. Allan Jamieson, M.D., F.R.C.P.Ed.,

Physician for Diseases of the Skin, Edinburgh Royal Infirmary.

One of these exhibited unusual features and terminated fatally; the other showed the more ordinary appearances and quite remarkable results from exposure to X rays.

Case 1.—The patient was a man æt. 66, who was admitted to the Royal Infirmary in May, 1901 He had had syphilis forty-three years before, but had had no "reminders." Three years ago transient lesions had occurred, and typical syphilitic scars could be seen on the inner aspects of the knees. A year ago an itchy scaly eruption had begun on the head and face, and partially on the limbs, becoming red, weeping, and crusted, breaking down into eroded or ulcerated areas, which scar over only to become raw again. The hair was completely destroyed over the parts of the scalp affected. No definite tumours were detected, there being only a superficial infiltration followed by extensive ulceration. Notwithstanding the atypical character of the lesions, the microscopic appearances were those which characterise mycosis fungoides. Antispecific and local treatment alike proved unavailing, the patient dying with marasmus and mental aberration.

Case 2.—The patient was a woman, æt. 54, who showed the classical appearance of mycosis fungoides, and was admitted in June, 1902. She herself and her children had always been healthy. There was a history of a premycosic stage of erythrodermia and itchy eczematoid lesions on head, lasting ten years. On admission there many tumours, some fungating and sloughing on the face, erythrodermic and scaly patches, and some tumours on the body. Under treatment with X-rays the tumours and eczematoid eruptions disappeared completely; the rays, however, did not wholly prevent new lesions appearing elsewhere, but these again yielded like their predecessors. Sixty sittings, lasting about one and a half hours each, were given. Each nodule was exposed to the rays of a soft tube for three or four minutes; there was no great reaction. Contrasting the two cases, the speaker pointed out that it first began as a scaly eczema turning moist and breaking down. Though there were no nodules, the microscopic characters were conclusive as to the nature of the disease. The previous syphilis seemed to have no bearing on the case, and the anti-syphilitic treatment did harm rather than good. The second case was typical — dry, scaly eczema and tumour formation. It was of interest to note that twice within two years the patient had suffered from erysipelas, an affection which was said to exert a beneficial effect in some cases of mycosis fungoides, without there having been any improvement whatever. As to the microscopic appearances, these were not such as to warrant any opinion on the nature of the affection, some observers looking on it as a sarcoma, some as a lymphadenoma, and others as an infective granuloma.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.

Meeting held Wednesday, November 5th, 1902.

Peter Horrocks, M.D., F.R.C.P., President, in the Chair.

PRIMARY CARCINOMA OF TUBE, WITH FIBROID UTERUS.

Mr. Bland Sutton showed a specimen, removed from a very obese married woman, who came complaining of a discharge of matter and blood in gushes from the vagina. She had had for some years a large abdominal tumour, which, under an anæsthetic, was found to lie in the hypogastrium, and appeared to be a fibroid. The uterus was much longer than normal. The diagnosis lay between a sloughing fibroid and a tumour of the endometrium. He removed the uterus and adnexa, and in the course of the operation he discovered that the left tube was twice its natural length, and passed on to the tumour, where it ended in a well-marked dilatation. This part was adherent to the peritoneal surface of the rectum. He arrived at the conclusion that it was a case of primary carcinoma of the Fallopian tube, which had protruded through the ostium and had attacked the rectum. The case suggested several interesting points. He had often been in doubt whether the disease began in the endometrium and then infected the tube, or *vice versa*. In this case it had unquestionably started in the tube. It was interesting to note that the gushes of blood must have come from the ampulla in the tube and he thought that this might be regarded as a crucial test that when there was blood in the ampulla and contraction took place it was propelled into the uterus. That was parallel with

---

(*a*) Paper read before the Edinburgh Medico-Chirurgical Society, November 5th, 1902.

what they found in extra-uterine gestation. There was six inches of healthy tube between the cancer and the uterus. He called attention to the fact that many men would have dilated the uterus in the presence of hæmorrhage after the menopause, and would have been surprised to find that the endometrium was healthy. He showed the fibroid uterus, which was 4½ inches in diameter, although it was nine years after the menopause, and this he suggested might help to destroy the superstition that fibroids tended to shrink after the menopause. In reply to Dr. Handfield-Jones he said he believed that view to be purely a superstition.

Dr. **Griffith** suggested that the specimen should be referred to a committee, adding that it seemed somewhat extraordinary that in presence of a fibroid uterus the author should assume that the blood came from the tube. It was years since he himself had shown a series of specimens to prove not only the possibility, but even the probability, of this occurrence. He had never examined a case of occluded tube which did not present a well-marked dilatation of the interstitial portion, and even when this was not visible to the naked eye it was evident under the microscope. He could not understand how the "gushes" of blood could pass through the length of healthy tube that intervened.

Dr. Gow observed that there were cases in which similar tumours after the menopause caused gushes of blood from the uterus, and he thought a malignant tumour in the tube would be likely to bring about the return of hæmorrhage.

Dr. **Handfield-Jones** recalled a similar case which he had some years ago. The uterus was enlarged, and the patient was supposed to have cancer of the endometrium. After several curettings the hæmorrhage returned, so the uterus was extirpated, but when they cut it open the endometrium appeared to be quite healthy. He therefore did not think it was necessary to have recourse to such an ingenious hypothesis for an explanation of the source of the hæmorrhage in the author's case.

The **President** questioned whether it was a fibroid tumour at all, for it looked very much like a sarcoma. With respect to the disappearance of fibroids after the menopause, he mentioned that in cases under his own observation some of them had diminished in size so much that it was quite impossible to feel them, so that it was certain they did shrink, even if not to total disappearance. The blood in extra-uterine gestation might come from the tube whether it were blocked or not, but he did not think that the author had proved conclusively that it came from the tube in his case. If the carcinomatous growth had not existed the presence of the fibroid would have been held to account for the hæmorrhage from the uterus. He agreed that the specimen had better be referred to a committee.

Mr. **Bland-Sutton** agreed to the suggestion and a committee was appointed.

EXTRA-UTERINE GESTATION IN UTERINE HORN.

Mr. **Bland-Sutton** also showed a specimen removed from a woman, æt. 29, the mother of two children, the youngest being 18 months of age. In July, 1901, she ceased to menstruate and thought herself pregnant. In October she suffered much abdominal pain, followed later on by attacks of pain culminating in false labour which continued off and on for three months, accompanied by the discharge of blood from the vagina. This went on until October 3rd of this year, when she came under his observation. On examining her he came to the conclusion that there was extra-uterine pregnancy with a dead child, and that the pregnancy was possibly, as suggested by the practitioner who had sent her, in the horn of a malformed uterus. On abdominal palpation he felt a large movable tumour of a globular shape, feeling just like a pedunculated subserous fibroid. The uterus was of normal size, and he could not make out any direct connection between the two. A month ago he performed cœliotomy, and removed the tumour, which had torn through some inches of the meso-rectum. This he repaired, but there was some oozing, and he drained for thirty-six hours. She made an excellent recovery. The fœtus was enclosed in a fairly thick muscular sac together with the placenta. It was on the left side of the uterus. He was unable to find either ovary or Fallopian tube. The sac was connected to the uterus by a broad band, but he could find no clue to its nature. From the muscular character of its sac and of the pedicle, and its being very movable, he thought it was probably pregnancy in the rudimentary horn of a unicorn uterus.

He also showed another specimen of the same kind. The patient was thirty-five years of age and the mother of one child, aged seven. She became pregnant in November of last year, but had slight shows at times, and in the early months she suffered more pain than usual. Her doctor thought there was something abnormal, and sent her on for advice. On examination a small rounded tumour was detected in the left half of the pelvis, which felt like a small subserous sessile fibroid and a decision was postponed. When she returned there was no pain, and on re-examination the mass had disappeared, the uterus was in its normal position, and its size was about that to be expected. He thought he must have made a mistake. In September she had a fruitless labour, and a month later she began to menstruate again. She again returned, and he then came to the conclusion that it was an extra-uterine gestation because he could feel the fœtus lying across the uterus. He performed cœliotomy ten days later and removed the fœtus, enucleating the placenta, which was about the size of a cricket ball. It was adherent to the bowel and a portion of the amnion had to be stripped off and left *in situ*.

SPONTANEOUS DELIVERY OF INFANT IN TRANSVERSE PRESENTATION.

Dr. **Comyns Berkeley** showed a full-term fœtus sent to Mr. Doran by Mr. Miles, of Stantonbury, which had presented transversely and had undergone spontaneous delivery. The mother's age was 29. She had been confined in 1895 with placenta prævia, again in 1897 of a healthy child at term. Her last confinement commenced on October 18th. During pregnancy she had suffered a great deal from pain, and the movements of the fœtus were very feeble. The pains came on on October 11th, and Mr. Miles diagnosed a dorso-anterior position. Several fruitless attempts were made to deliver with the forceps, and later in the day spontaneous delivery took place, the fœtus being dead.

PARATUBULAR HÆMATOCELE.

Dr. **Vine Bell** showed a specimen removed from a woman, the mother of five children, last child thirteen months previously, had not menstruated since. Three months ago she lost blood *per vaginam* for a month at a time. Eleven weeks ago she was seized with severe pain associated with great increase of the hæmorrhage with clots and vomiting. The attack was repeated several times with retention of urine and dysuria. She kept her bed and recovered to some extent. Little could be made out on examination beyond a mass on the left side of the uterus the size of a billiard ball, tender to the touch. No absolute diagnosis was made, but the abdomen was opened and the specimen was removed. There was no other hæmorrhage in the abdomen. The specimen consisted of a rounded mass of clot adherent to the tube wall externally, *e.g.*, a paratubal hæmatocele.

Mr. **W. Sampson Handley** read a paper on

PARATUBAL HÆMATOCELE.

He pointed out that encysted hæmatocele, with a fibrous sac clasping the ostium, and independent of, though perhaps partially adherent to, the viscera (peritubal hæmatocele) was first described by Sänger and Taylor. It is more frequent than is commonly believed, since the sac has often been mistaken for a portion of the tube. Its capsule consists of fibrous tissue, not of fibrin. All encysted hæmatoceles arising from tubal bleeding are described by Sänger and Taylor as peritubal, and therefore, necessarily, as the result of hæmorrhage from the ostium. The object of this paper is to show that tubal rupture may produce an encysted hæmatocele adherent to the tube, and enclosing the rupture in its wall. Such a hæmatocele is not peritubal, but rather paratubal. Its sac may be mistaken for a part of the tube. These statements are chiefly based on a re-examination of specimen 2,480 in St. Thomas's Hospital Museum, removed by Dr. Cullingworth, and described in the catalogue as a sacculated hæmato-salpinx. Clinically the symptoms of the case were eleven weeks' amenorrhœa, followed by vaginal hæmorrhage and recurrent bearing-down pains during the three months which elapsed before operation. There was a soft elastic swelling in Douglas's pouch; the right appendages were absent from their normal situation; right tubal mole was diagnosed, and recovery followed operation. The specimen was reported on by a committee of this Society, but no definite opinion was expressed as to its nature. Re-examination shows a healed rupture in the wall of the tube where the blood sac is adherent to it. Muscle is absent from the wall of the blood sac, which exactly resembles the wall of a peritubal hæmatocele—that is, it consists of fibrous tissue organised from peritoneal lymph, not of fibrin. This and other evidence negatives the supposition that the wall of the tube took any share in the formation of the wall of the blood-sac. A search through the literature has supplied one example of paratubal hæmatocele in a modified form (part of the mole lay in the sac of the hæmatocele, part in the tube), and two connecting links or intermediate forms between peritubal hæmatocele and the typical paratubal hæmatocele now described. It seems probable that the slow bleeding which forms an encysted hæmatocele does not, as is generally held, precede, but goes on *pari passu* with the formation of the sac. Moreover aneurysmoid distension of the developing sac, by continuously altering its relations to the surrounding peritoneal surfaces from which it is derived, separates it from them, and accounts for the otherwise inexplicable tumour-like individuality of the hæmatocele. The original lymph thrown out round the rupture, instead of being stretched out in the form of bridles or membranes, is evenly distended into a complete spherical sac surrounding the blood. The author suggests the word dynamocele as appropriate to such a product of fluid pressure.

Dr. Eden showed a specimen removed twelve years ago at the Chelsea Hospital, consisting of the Fallopian tube, cut through about the middle with an oval blood clot attached to the upper part. This had the general characters of a tubal mole except at the outer end, where there was a little curved thread-like projection. The clot was intimately adherent to a very small part of the tube, and there the wall of the tube was very thin. He thought there had been a rupture of the tube, and that the rupture had subsequently healed. He supposed, however, that it was really a paratubal hæmatocele. He failed to find any trace of villi in the blood clot, and there was no evidence in the tubal mucosa of the occurrence of pregnancy. He pointed out that it was very difficult to exclude the presence of villi unless one examined the whole of the specimen. The small size of the rupture proved nothing, because they knew how the tube retracted after the escape of the clot.

Dr. Cullingworth observed that it was very important to have proved that in all probability a rupture of the tube could take place and a hæmatocele form, followed by the closure of the laceration.

Mr. Bland-Sutton pointed out that the mole might not be larger than a pea, so that in a case of this sort there may have been a small mole which escaped detection. He had seen them form around fluid effused into the tube in acute salpingitis. Some years ago he had published a very perfect case of the kind, and there was no blood in the tube at all, only clear fluid. They must therefore look for something beyond blood-clot to account for them. He observed that if they put a piece of gauze into the abdominal cavity to drain it, and noticed what a large quantity of lymph and organised lymph collected in and around the gauze they could easily account for the appearance outside the tube. The author's object, he imagined, was to prove that these cyst-like bodies might form elsewhere than round the fimbriæ. They might, however, form around accessory ostia.

Dr. Griffith said it would simplify matters if they used one term to cover both conditions. The contents were the same wherever it formed, whether along the tube or at the ostium. Intra-uterine fibrinous polypi presented certain points of resemblance with this condition. In any event the term "paratubal" should not be used.

The President agreed that the term "paratubal" was unsuitable. It must be a slow formation and probably first of all the peritoneum was intact and gave way later, but not until there had been coagulation and the formation of a well-defined clot. This might explain why the blood did not flow freely into the peritoneal cavity.

Dr. W. S. Handley, in reply, suggested that floating appendicular abscess was probably of the same nature, and he was on the look out for some to examine. He pointed out that the pressure of the peritoneum would not explain its production, because the same thing occurred at the ostium. He aslo suggested that questions of nomenclature ought to be dealt with by the Society as an official body oftener than was done.

THE BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.

The Annual General Meeting was held on Friday, Nov. 7th, 1902, at the Medical Society's Rooms, 11, Chandos Street, Cavendish Square, W.

The President, Dr. John Macintyre, of Glasgow, in the Chair.

After the minutes of the last meeting had been read by the Secretary, and approved and adopted by the Fellows present, the election of the following officers for the ensuing year took place:—President: Dr. Wyatt Wingrave. Vice-Presidents: Dr. Hillis (Dublin), Mr. Bark (Liverpool), Dr. Robert Woods (Dublin). Council: Dr. Macintyre (*ex-off.*); Metropolitan: Dr. Kelson, Mr. Claude Woakes, Mr. Atwood Thorne, Dr. Hawthorne; Extra-Metropolitan: Dr. Scatliff (Brighton), Dr. Fullerton (Glasgow). Hon. Secretaries: Mr. Chichele Nourse, Dr. P. H. Abercrombie.

Before vacating the chair Dr. Macintyre, the retiring President, expressed his sense of the great loss they had sustained by the death of Mr. Lennox Browne, who had always worked hard to further the interest of the Association.

On taking the presidential chair Dr. Wyatt Wingrave moved that a suitable letter of condolence be sent to Mrs. Lennox Browne. This was seconded by Mr. Mayo Collier, and it was unanimously agreed to forward to Mrs. Lennox Browne a suitable letter of condolence.

The following Clinical Cases were then shown:—

A case of foreign body (a penny) in the œsophagus, located at once by the X-rays, and which had escaped detection by bougies, &c. Shown by Dr. Macintyre The X-ray photograph was shown by means of the stereoscope, and the penny was exhibited much corroded.

A case of malignant growth in the larynx, by Mr. Mayo Collier.

A case of myxo-sarcoma in the nasal cavity, by Mr. Mayo Collier. Opinions of the Fellows were invited as to what procedure should be adopted in the way of treatment in this case.

Mr. Bark spoke of a similar case of his own where he removed the growth with snare and forceps, and it returned in a fortnight. He then excised the upper jaw, and again it returned. He thought it was a very difficult question to decide what to do in these cases. Perhaps in this particular case the upper jaw might be removed.

Mr. Stuart-Low was against any severe operation unless in the very early stage, and he referred to a case where, at the operation of excision of the upper jaw, it was found impossible to remove all the disease.

Dr. Macintyre thought it was impossible in this case to remove all the disease, and he spoke of the very great success he had had in a similar case, where he used the electrical treatment, details of which he had given at a former meeting.

Dr. Jobson Horne thought it was very desirable in such cases to have a microscopical preparation of the growth.

The President remarked that the microscopical evidence in such cases was at times conflicting. What apparently was true sarcoma microscopically sometimes was innocent clinically. He requested that a slide be shown at the next meeting.

Mr. Mayo Collier, replying, said he did not intend to operate on his patient as he believed the whole growth could not be removed, the cribriform plate being already, in his opinion, involved.

A case of displacement of the nose, by Mr. Mayo Collier. This patient had been operated on, and with excellent results.

Mr. Bark and Dr. Macintyre congratulated Mr. Mayo Collier on the good result of his treatment, and thought that still further improvement would take place.

A case of wandering rash on the tongue, by Mr. Mayo Collier.

A case of nævus of the palate, fauces, tongue and epiglottis, by Dr. P. H. Abercrombie.

A case of pachydermia laryngis, by Dr. Wingrave.

Mr. Mayo Collier was inclined to regard the case as one of laryngitis due to alcohol or syphilis.

Dr. Jobson Horne advised against local treatment, and was in favour of rest of the voice and general hygienic measures.

A case of hyperacusis, by Dr. Wingrave.

A case of new growth of the epiglottis, by Dr. Jobson Horne.

Mr. Mayo Collier regarded it as a case of syphilis, and advised suitable treatment.

Dr. Kelson thought it might be a tuberculous mass.

Dr. Wingrave expressed some doubt as to the origin of the growth being in the epiglottis. It was a case difficult to diagnose clinically, and he advised the removal of a piece for microscopical examination.

Dr. Jobson Horne said he would have this done, and if tubercle were disproved he would at once begin thorough anti-syphilitic treatment. He himself was inclined to regard the case as an unusual form of lupus.

A case of fixation of right vocal cord, by Dr. Jobson Horne.

Dr. Kelson thought this was due to epithelioma at the juncture of the larynx and œsophagus, as there was an enlarged gland present, and some dysphagia.

Mr. Stuart-Low showed an "anatomical" tonsillotome, and an improved stilletted Eustachian catheter.

The Presidential Address on "Tobacco in Nerve-Deafness" was postponed until the next meeting.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held November 5th, 1902.

Sir Thomas Fraser, President, in the Chair.

Dr. Byrom Bramwell showed cases of tabes, multiple sclerosis, and syringomyelia treated by Frenkel's plan of co-ordinated muscular exercises. The first case was a married woman, suffering from the symptoms of locomotor ataxia, who could not walk on account of the inco-ordination. She had been confined entirely to bed for five months at the date of the commencement of the treatment. Within three weeks of the time she began the exercises she could walk in a go-cart, and five months later could get about fairly easily with the aid of two sticks. The second case was one of disseminated sclerosis in a young woman who had been under observation for two years, and showed all the characteristic signs of the disease. She had been bedridden for three months, but after treatment on Frenkel's plan could walk with the aid of a stick. The third patient was a woman, æt. 21, who was admitted to hospital six weeks before. She had been unable to walk for five months, and presented signs of spastic paralysis of the legs, paresis of the upper limbs, with atrophy of the muscles of the hands and shoulder girdle. There was well-marked dissociation of sensation over the arms and front of the chest, ordinary sensibility being retained, while that for heat, cold, and pain was lost. Below these levels only tactile sensibility was impaired. This patient could also walk now, as a result of Frenkel's exercises. Dr. Bramwell did not wish to lay too much stress on the effect of this line of treatment except in tabes, in which it was undoubtedly very beneficial; in disseminated sclerosis remissions were notoriously common; still, he thought that the exercises had produced benefit in the patients suffering from this disease and from syringomyelia.

Dr. F. D. Boyd showed (for Dr. Gibson) (1) A case of acromegaly. The patient was a woman who had first begun to suffer from headache five years ago, and subsequently noticed that her hands and feet were becoming larger. The face showed the characteristic elongation, from increase in size of the maxillæ, there was optic neuritis, but no hemianopsia, and the state of the thyroid was doubtful, but the gland was probably atrophied. (2) A case of pseudo-hypertrophic paralysis. Three brothers and a sister of the patient had died of some acute cerebral affection. The calves and triceps muscles were enlarged, while the muscles of the shoulder girdle and the adductors of the legs and extensors of the feet were atrophied.

Mr. Alexis Thomson showed a boy, æt. 16, who, after a crush between buffers developed a traumatic cyst of the pancreas. When admitted to hospital a tense cystic swelling was found lying above the umbilicus, and on opening the abdomen it was seen that it was due to a collection of fluid in the lesser sac of the peritoneum. Above it lay the stomach, and below it the transverse colon. After the sac was opened and drained, the left lobe of the liver was raised, when it was found that a perforation of the stomach had occurred at the time of injury and that this had been closed by the adhesion of liver to the gastric wall. The closure of this perforation was a matter of some difficulty, and was effected by replacing and suturing the lobe of the liver which had been disturbed. The cyst was opened into by tearing through the meso-colon, and three or four pints of brownish fluid were removed.

Mr. H. J. Stiles showed (1) A girl, æt. 4, showing the very rare congenital deformity of umbilical urinary fistula. The parents were first cousins, and another child had supernumerary digits. (2) A case of spina bifida and hydrocephalus. (3) A case of recovery after operation for tuberculous disease of the temporal bone. The disease of the bone was so extensive as to make the case seem very hopeless; there was, in addition, a large mass of glands on the same side of the neck. The greater part of the temporal was removed, the structures in the inner and middle ear being exposed in so doing, and the wound had cicatrised. The child was so healthy now that he proposed removing the glands. It was advisable in such cases first to deal with the caries of the temporal, and subsequently to treat the glands.

Mr. C. W. Cathcart showed (1) A patient after trephining for severe fracture of the skull, the symptoms on admission being unconsciousness, œdema of the left side of the scalp, rigidity of the right leg, and dilatation of the left pupil. After the operation there had been a great deal of mental aberration, lasting for about three weeks, but the patient ultimately made a perfect recovery. (2) The result after operation for an unusually large cholesteatoma of the temporal. The cavity in the bone after the tumour was removed was such that a small pigeon's egg could be inserted into it.

Dr. Chalmers Watson exhibited a series of photographs illustrating some clinical and pathological appearances of chronic disease of the nervous system in horses.

Card Specimens.

By Dr. Harvey Littlejohn: (1) Two cases of fracture of the sternum, with rupture of the heart, produced by direct violence. (2) Suicidal stab wound of the heart, produced by a pair of scissors. (3) Hæmorrhage into the cerebellum, causing sudden death in a boy, æt. 18

By Dr. Alexander Bruce: Dissecting aneurysm of aorta.

By Mr. Caird: (1) Large gall-stone removed from the gall bladder of female, æt. 65. (2) Parts removed after excision and end-to-end suture in a case of malignant stricture of the colon (ascending colon, ileum, and cæcum), and showing also the ileo-cæcal valve and valve of Gersuny. (3) Prostate removed after the method of Freyer.

By Mr. C. W. Cathcart: (1) Sarcoma of femur. (2) Bullet lodged in lumbar vertebræ. (3) Tumour of soft palate.

Dr. W. Allan Jamieson read a paper on "Two Cases of Mycosis fungoides," which will be found on page 517.

Dr. Norman Walker alluded to the great difficulty which sometimes attended the diagnosis of very late syphilitic lesions, and pointed out that these are very much less amenable to iodide of potash than the ordinary earlier tertiaries. He thought it had not been sufficiently emphasised that mycosis fungoides was invariably fatal, and he himself had given a very gloomy prognosis about two years ago in the second of these cases. The very striking improvement after exposure to the Röntgen rays was, therefore, of great importance. Only two cases had, so far as he knew, been treated in this way, and both of these had shown very marked benefit.

Dr. Jamieson's paper was illustrated by drawings and microscopic specimens.

Dr. Aitchison Robertson read a paper on

CONTRIBUTIONS TO THE STUDY OF THE LOCAL DISTRIBUTION OF CANCER IN SCOTLAND.

The communication, he said, was chiefly designed to draw the attention of the medical profession to the importance of the subject. The reason for undertaking the work was that no studies of the kind had hitherto been attempted in Scotland, although similar investigations were being pursued in the Midlands, in Germany, and in America. According to the Registrar General's statistics the mortality varies greatly in the different counties, and one of his objects was to see how far the ordinary topographical characteristics of these counties agreed with those of other localities in which cancer was correspondingly common. There was a consensus of opinion that, making all allowance for improved diagnosis rendering death certification more accurate, cancer was slightly on the increase. Sir William Banks had pointed out that the diagnosis of cancer was as easily made forty years ago as it is to-day, and probably the improved certification was not enough to account for the increased mortality. Cancer maps, showing the distribution of the mortality, were less useful when applied to Scotland than to other countries on account of the distribution of the population between large, comparatively sparsely populated rural districts and a few large towns. In the latter the presence of hospitals vitiated the statistics to a great extent. He had taken the Registrar-General's statistics for the years 1895-6-7, and had endeavoured to correct them as regards the actual residences of cancer patients by a system of inquiries among practitioners in all parts of Scotland, and by the investigation of hospital registers. Even in the last named the causes of death were very loosely stated, and still more so in the ordinary death certificate, as was shown by the fact that in 1895 no less than 600 deaths had been transferred from other heads to that of cancer as a result of special letters of inquiry sent out by the Registrar-General. From his corrected data he had prepared a map for comparison with one based on the Registrar-General's figures. The average mortality from cancer was about four, and the general result of the corrections was to lower the mortality in towns and to raise that of rural districts. In the Registrar-General's returns the towns, on account of the existence of large hospitals, showed a high cancer mortality. Dr. Aitchison then took up some of the alleged causes of cancer—geological formation, topography, humidity as regards soil and rainfall—and found that none of these could explain the cancer distribution in Scotland. Neither was there any evidence that a special food habit, such as fish eating, alcohol, &c., had any influence. He thought there was a clear case for the appointment of a committee of investigation of the distribution of cancer, and that it was most important that great attention should be paid to local details of its incidence, and that the cases arising in groups in different localities should be studied with a minuteness which had been impossible to him.

Dr. Macmillan alluded to the comparative frequency of cancer in certain parts of Arran. Dr. Harvey Littlejohn thought that any possibility of cancer being due to the geological or topographical nature of a locality might be dismissed. Had any such connection existed it would have been discovered long ago. His only conclusion on Dr. Aitchison Robertson's paper was that the mortality was not corrected for age, and he suggested that the different age distribution of the population of the towns and of the country required consideration in determining whether cancer was actually more frequent in one than in the other. Dr. Bashford, the newly appointed superintendent of the cancer research laboratory, Dr. Walker, and the President also spoke.

Dr. Dawson Turner read a paper on "The Treatment of Cancer by Photo-Therapy," which we publish in abstract elsewhere.

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, Nov. 9th, 1902.

Appendicitis.

The subject of appendicitis is inexhaustible; it crops up at almost every surgical congress and every meeting of the Société Chirurgical. This time the question of expectancy was discussed by M. Segond, who considered that many fatal cases were due to hesitation on the part of surgeons to operate. He related the facts of a case in point. A young woman, who had suffered for several months from hepatic colic, was suddenly seized with sharp pain in the right iliac fossa. It was only forty-eight hours afterwards that perforation of the appendix followed by general peritonitis was recognised. In spite of the extreme gravity of the situation the speaker performed laparotomy as the only chance of saving the patient. The appendix was found to be gangrened. Death took place three days following. He was convinced that the woman would have recovered if she had been operated on at an early period, for he had seen several patients with gangrene of the appendix get well when operated on within the first few hours. He believed that the time had arrived to publish all cases of death due to temporisation, for there existed in the systematic application of that method a danger which should be denounced.

Tetanus.

M. Claude communicated the case of a man, æt. 46, who, five days after a very slight wound on the little finger of the left hand, was seized with intense general contractions, fever, delirium, &c. An injection of antitetanic serum was immediately given, and each day following an injection of four grains of phenic acid, according to the method of Baccelli. Besides this treatment, blood-letting was practised, chloral given in large doses, and the offending member amputated. For several days the patient had in no wise improved, but finally the fever declined, tetanic symptoms disappeared, and finally the cure was effective.

M. Chauffard related another case treated in the same way, but the results were not so fortunate. A man while drunk, was struck on the head by an iron instrument. He fell to the ground and the wound was soiled by the dust. Six days afterwards, signs of tetanus set in. He was given an injection of serum two days in succession, and besides, four injections containing one grain each of phenic acid. An enema of chloral was also given. The man succumbed, however, the following day. The speaker was inclined to think that the amount of phenic acid might have been considerably increased as Baccelli recommends from five to eight grains in the twenty-four hours.

M. Vallas said that, in spite of five unsuccessful cases which had been published, the preventive value of anti-tetanic serum was fully proved, and, if the method were applied to every person that was wounded, tetanus would disappear from human pathology. Unfortunately that ideal was impossible to attain, as tetanus was too rare for it to be generally accepted, yet the preventive treatment was formally indicated in cases of contused and lacerated wounds soiled with earth or other *debris*. Ten grammes of the serum should be injected on the first day, again on the third day, and finally on the fifteenth day; and if the wound did not show disposition to heal, and especially if local complications existed susceptible of favouring the vegetation of the bacilli of Nicolaïer, it would be prudent to renew the preventive injection every fortnight.

When the tetanus was declared, we should admit ourselves disarmed. However, serotherapy constituted even at that moment an important resource. The injections have been made subcutaneously, intracerebral, intravenous, and under the arachnoid. Intracerebral injections had the enormous disadvantage of being far from inoffensive. Whereas but slight accidents had been caused by the subcutaneous or intravenous methods, the cases were not rare where the intracerebral injection had caused the death of the patient. That method should consequently be rejected absolutely. The same may be said of the subarachnoid method.

He had been able to collect 373 cases of tetanus treated by subcutaneous injections of the serum, with 145 deaths and 228 cures, or a mortality of 39 per cent. By the old treatment the mortality was 70 per cent., consequently it was evident that serotherapy had lowered the mortality considerably.

Chloral by the mouth or by enemas, and hypodermic injections of phenic acid constituted symptomatic treatment and were given to act on the contractions; they should only be regarded as auxiliary means, but it was well to utilise them at the same time as the serum.

Hydrocele.

Chloride of zinc, gr. xv.;
Water, ℥ijss.

After removing one or two ounces of the liquid, according to the size of the tumour, inject five to twenty drops of the caustic solution by means of an ordinary hypodermic syringe. A rapid cure follows without causing the slightest complication.

Germany.

[From our own Correspondent.]

Berlin, November 8th, 1902.

Cancer Literature.

The *D. Med. Zeit.* is devoting a series of supplements to this important subject, in order that its readers may be in a position to know all that is written about it throughout "the civilised world."

The first reference is to an article by Carl Kolb on the spread of malignant new growths in South Germany. The most important outcome of the article is that the highest mortality is found in a continuous stretch of country, bounded on the north by the Danube and the Jura, and on the south by the Alps, and extends from Vienna over the high plateau of Bavaria and Swabia to Geneva. This region corresponds almost exactly to the tertiary formation with diluvium, and is distinguished by the physical and chemical properties of the soil, where there are depressions, shallow valleys, peaty and swampy spots, and extensive clay soils. Some features point to a parasitic origin, such as local differences of frequency, local and house epidemics, temporary variations in frequency.

Riechelmann gives some statistics from a pathological point of view. During the period 1895 to 1901 there were 711 autopsies in the Friedrichshain Hospital, Berlin, on cancer cases. In a large number (nearly one-fourth) the disease was not recognised during life. The tables given are too extensive for reproduction here, but some of the facts are of special interest. Out of 288 cases of cancer of the stomach a connection between the cancer and ulcer of the organ was shown only in fifteen cases. In thirty-nine cases of malignant disease of the gall bladder biliary calculi were found in twenty-six of them, nearly in two-thirds of the cases. As regards cachexia, he finds this essentially dependent of the site of the disease in the intestinal tract, the ulceration of the tumour and metastasis. In conclusion the connection is given between the primary growth and the metastasis, in which some very instructive material for the investigation is to be found.

As English literature on the subject is accessible to all, the papers of Foulerton and Hillier may be passed over with bare mention.

J. Jensen, Copenhagen, relates some experiments with cancer tumours. He found, as did Moran, that adeno-carcinoma could be communicated to white mice, and from them to others in lengthened series. The tumour mass was indurated with physiological solution and injected. In the course of months a distinct tumour develops, which proved to be typical carcinoma. If the cells were destroyed by induration with Kieselguhr no cancer development followed, but then vitality was not destroyed by keeping the cancer tissues four days in the ice chest. Attempts to transfer the disease to rabbits, guinea pigs, and white rats failed. Like other investigators, he endeavoured to discover a curative serum. He injected tumour material into rabbits, and with the serum of these animals treated mice who had already developed malignant tumours. In those with small tumours complete resorption took place, in those with large ones decomposition of the tumours and rapidly fatal cachexia. Control experiments showed the complete absence of any influence in normal rabbit serum. The writer believes therefore that the serum of rabbits previously treated has a specific effect on the disease.

E. von Leyden and F. Blumenthal publish a preliminary contribution on some results of investigation. Their attempts at transference of the disease to animals were all without result; but cancer in the dog was repeatedly transferred to other dogs. Experiments on the production of a curative serum were made by injecting the cancer serum of dogs into rabbits for several weeks together. A cancerous dog was then injected with this serum. After some time softening and liquidation of the growth took place, and after several weeks complete disappearance of the tumour.

In a second dog with carcinoma recti (two tumours the size of a plum) fresh tumour juice from another dog was injected. Both tumours disappeared in the course of five months, except a small residuum.

Similar experiments were then made on the human subject. A woman, æt. 56, with cancer of the bladder, was injected with human cancer juice. The cancer cells previously present in the urine disappeared and the nutrition improved. The woman died some time after of cardiac weakness, and the autopsy showed that the bladder tumour, at first the size of an apple, had shrunk materially, and that the affected lymph glands had become normal.

Another woman, with carcinoma uteri, was treated for months with human cancer juice. At the autopsy no metastases were found.

Another woman, æt. 42, with cancer of the uterus, was treated for some weeks with serum from a goat that had previously had tumour extract injected; later on the tumour extract was injected direct. The tumour appeared in part to undergo some decomposition. Although recovery did not take place, a material improvement took place in the general condition. V. Leyden sees in Jensen's experiments related above a firm experimental basis for further investigation. Korbsch, *Neue Med. Presse*, proceeds from the fact that cancer is exceptional under twenty, and assumes therefore that youth affords a protection against the disease. Sheep also are exceptionally free from the disease, so he wasled to treat cases with mutton serum from freshly-killed animals. They were treated for months together with from 30 to 50 grammes of serum daily either by mouth or subcutaneously.

The cancerous cachexia improved slowly, a fresh appearance was put on, the blood vessels filled, and the cancerous tissues were destroyed.

Carcinomata of the surface decomposed and cicatrised in part; in others residual parts of tumours remained behind that defied all treatment, but the author believes that if a method could be made use of by which larger amounts of serum could be incorporated better results might be obtained. Unfortunately, more than 50 grammes could not be given per diem as fever was set up. He hopes that drying of the serum *in vacuo* would permit of curative doses being given.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, November 8th, 1902.

LABYRINTH ANOMALY.

AT the "Gesellschaft der Ærzte," Alexander, in conjunction with Professor Kreidl, gave an account of their experiments with deaf cats and Japanese dancing mice.

The congenitally deaf cat is insensible to loud sounds but sensible to the cyclostat, which proves that the vestibular apparatus is intact. The post-mortem examination showed an absence of mucous membrane in the cochlea as well as of the corti apparatus, with degeneration in the sacculi of the ampullæ. The labyrinthal pigment was absent in many places and greatly reduced in others.

In the Japanese dancing mice, which have been cultivated for the last hundred years, there was a similar absence of many of the parts without any reaction with the cyclostat, whilst there was a normal reaction to the galvanic current.

Histological examination showed an atrophied condition of the spiral ganglia and cochlear nerve fibres, as well as of the vestibular ganglia. There was also marked defect in the neuro-epithelium of the nerve endings.

The changes in these dancing animals are congenital, and are carefully selected for propagation owing to the amusement they give by their gyrating freaks that have earned for them the name of "dancing mice." Alexander concluded by saying that he had not yet examined the intra-uterine state of these animals.

"DECOLLEMENT TRAUMATIQUE."

Fuchsig showed a case of "decollement traumatique," the patient being a woman who had been crushed between two wagons, detaching both trochanters. Gradually after this injury a tumour began to form in the right groin of an irregular shape and soft consistence, which, from the amount of lymph effused, appeared to arise from the superficial fascia. Effusion of blood in the fascia of the abdomen is an unusual condition, and was not explained till the investigations of Morel-Levalée put it beyond doubt. Since that time Gussenbauer and Köhler have confirmed the opinion that the tissues are temporarily paralysed by severe pressure which may not have gone so far as to produce a visible solution of continuity, yet the structure has been so weakened and the contractile power so lowered, that the tissue becomes spongy and unable by its own resistance to expel the fluid.

Being a case of disturbed sensibility the proper mode of treatment would be puncture, incision, or injections of irritating lotions.

ANATOMICAL PATHOLOGY OF THE GALL DUCTS AND PANCREAS.

At the "Naturforscher" Bunger gave an anatomical lecture on the relation of the gall ducts to the pancreas and the importance in the surgery of the parts. It was not enough to remove the stone from the choledochus of the patient, but also from the whole length and smaller ramifications if possible. To determine the exact course of the duct he carefully examined 58 dead bodies, and found that in 25 per cent. of the cases the choledochus ran through the pancreas, while in 5 per cent. only did it run through the head of that viscus, having to be divided at least two centimetres away. The pancreas in every case was firmly adherent to the duct. The choledochus and Warsung's duct were in combination in only 2 per cent., and in 98 per cent. passed separately into the duodenum at 0·2 centimetre distance. Warsung's duct was also free in its whole course, crossing and recrossing the ductus choledochus except in 10 per cent.

The practical lesson to be deduced for the surgeon is, that the choledochus may be opened in its whole length, except in the part near its entrance into the duodenum, without seriously wounding the pancreas. Unless the head of the pancreas be very large, or some other morbid change of the pancreas be suspected to be giving rise to compression of the ductus choledochus it need not be opened. In such a case the symptoms would point to a lesion in the pancreas in addition to the gall-stone.

Another point should be borne in mind, viz., that the two ducts open separately into the duodenum, and must be carefully repaired if wounded, as the secretions are conducted separately into the duodenum. If catarrh of the duodenum causes a swelling of the papilla duodenalis, the secretion will be retained in the ampulla, and a calculus form, not only in the ductus choledochus but also in the pancreatic duct, which may also be produced by a misplacement of Warsung's duct.

Stolz said the principal cause of gall-stones was either blocking up of the biliary canals or infection. In the majority of the cases he had examined he had not found any new stones forming. He was strongly of opinion that no attempt to dissolve these contents was likely to be attended by success.

The Operating Theatres.

CANCER HOSPITAL.

Large Broad Ligament Tumour.—Mr. Bowreman Jessett operated on a married woman, æt. 52, who had been admitted for a large abdominal tumour. Her father had died of tumour of the brain. About seven years ago the patient noticed a lump in the abdomen, which gradually got larger. No treatment was resorted to. On admission two distinct lumps were felt on the upper part of the abdomen, over which there was a dull percussion note; there was no fluctuation. These lumps appeared to be connected with another hard mass extending into the pelvis. A further tumour was felt just above the pelvic lesion on the left side. *Per vaginam* the cervix was found pressed firmly against the vaginal wall anteriorly, there being a solid tumour at the back of the cervix, pushing it forward. The patient had frequent desire to micturate; menstruation was regular, lasting three to four days; there was no metrorrhagia. Under ether Mr. Jessett cut down and found a large fibroid extending up to the ensiform cartilage. The tumour had a large mass on the left side imbedded in the left broad ligament, which last was stretched completely over the tumour, extending considerably above the umbilicus. Numerous very large distended veins were stretched over the tumour. Strong adhesions bound the whole down in the pelvis; these were separated with considerable difficulty. Mr. Jessett then introduced Doyen's myoma screw into the posterior part of the tumour, and drew it forward through the abdominal wound. The capsule enclosing the tumour was divided round after being ligatured in sections and, after the hand had been passed down, was separated from the tumour itself, which was then delivered. The uterine arteries were secured, and the cervix uteri divided. The broad ligament on the opposite side was ligatured, the vessels secured, and the entire mass removed. The patient was kept in the Trendelenburg position during the operation. The tumour weighed 12 lbs. 13 ozs. During the latter part of the operation when the capsule was being peeled off, the left ureter was discovered running across the upper and anterior surface of the projecting mass of the tumour. The ureter was completely buried in a mass of adhesions and had been evidently ligatured and divided with them at the earlier stage of the operation. It was not discovered that the structure had been cut until the latter part of the operation. Most careful search was made for the upper end, but it could not be found, and as it had undoubtedly been ligatured and the patient was considerably collapsed, the search for it was abandoned, the lower end was freed from the tumour and ligatured, and about six inches of it removed. The ureter had been very much stretched over the tumour and the upper end must have contracted very considerably. Mr. Jessett said the interest of this case consisted in the first place in the size of the tumour situated entirely in the broad ligament, extending as it did up to the cartilages of the ribs on the left side, but causing comparatively few symptoms beyond the inconvenience of so large a mass being present. Secondly, in the fact of the ureter having been stretched completely over the top and front of the tumour, and imbedded in adhesions, so that it was not discovered until quite late in the operation, when the patient being in such a condition that it was thought inadmissible to subject her to further operative proceedings. Had the upper end of the ureter been discovered, Mr. Jessett pointed out that he would certainly have united it with the lower end by invaginating the upper into the lower by means of either splitting the lower end or by adopting the method suggested by Maunsell for uniting intestine. When it was found impossible to discover the upper end he said the question arose of removing the left kidney, but the patient's condition forbade this, and it was hoped that the ureter having been ligatured, hydronephrosis would naturally follow, but that the kidney eventually would become atrophied.

Registered for Transmission Abroad.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5 0s. 0d.; Half Page £2 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 12, 1902.

INFANT LIFE PROTECTION.

The talented author of "The Invisible Man" and other remarkable romances, who recently showed himself the prophetic essayist in "Anticipations," has now turned sociological teacher, and in the October number of the *Fortnightly Review* deals with the prosaic subject of "The Problem of the Birth Supply" in a manner at once critical and suggestive. Mr. H. G. Wells shows us that every minute seven new citizens are born into the great English-speaking community which is scattered under various flags and governments throughout the world. The question awaiting a satisfactory answer is: How may the quality of the average birth be raised? There are many fallacies in the popular answer, which vaguely advises, in ambiguous phrase, "the survival of the fittest." But it is not with Mr. Wells's "Mankind in the Making" that we are concerned at the present moment. As a preliminary to any such criticism it is necessary to face some of the ugly facts regarding the present situation as regards infant life mortality. Dr. Milson Rhodes recently showed that the present mortality of infants under one year of age was to-day as high as it was fifty years ago. The year 1900 afforded the highest mortality rate on record, 163 per 1,000. The Registrar-General's report for 1900 states that of 927,062 children born, no less than 142,912 were dead before the age of one year was reached. Truly, it is somewhat ludicrous to talk of the children of to-day being "the men of to-morrow" with a mortality like this. It is interesting to note the great variation which occurs in the different counties. In Wiltshire, Dorset, and Rutland the infant mortality is less than 100 per 1,000 births; in the last-named county the ratio is as low as seventy-nine, comparing most favourably with the average of 154 for England and Wales. But in the county of London the mortality is 160, and other counties are higher: Stafford 178, Warwick 175, Nottingham 176, East Riding of York 179, and Lancashire 180. Dr. Rhodes seeks to show that where there is what he calls marked "illiteracy" among the married women, there a high rate of infant mortality exists. Another fact is clearly elicited, namely, that the counties with the highest mortality are those where the people are principally employed in mining or manufacturing. Miss Frances Zanetti, whose work as inspector in Manchester is well known, in a recent paper has clearly indicated the chief etiological factors in the "slaughter of the innocents." "A large proportion of mothers have absolutely no knowledge of the proper way of bringing up their families. They feed and clothe their children improperly, and neglect the most elementary sanitary precautions, thereby making their homes veritable hothouses for disease germs of all kinds. Young babies are fed on bread and starchy foods, and in many cases have in addition exactly the same diet as the rest of the family, including bacon, potatoes, currant buns, stewed tea, and even beer! They drink cheap condensed milk and water out of filthy long-tubed bottles, are frequently left unwashed until late in the day, are exposed to the broiling sun in the summer and to the cold winds of winter and spring, and when they are not stifling in stuffy, dirty kitchens, are probably lying close to ashpits, or to street drains blocked with filth." The picture is true to life. Indeed, the wonder is that so many survive the rough weather of infancy. It is interesting to know that after nearly five years' experience the advantages of the Infant Life Protection Act of 1897 have been amply demonstrated. The chief object of the Act provides that: "Every person receiving or maintaining for hire or reward more than one infant under five years of age, or adopting an infant under two years of age for a lump sum paid down, and not exceeding £20, shall, within forty-eight hours, notify the fact to the local authority, and give the name and address of the person from whom they received the children." Dr. Kelynack, at the recent International Congress for the Welfare and Protection of Children, advocated an extension of the Act, the abolition of the distinction made in the present Act between one and more than one infant, and the abolition of the distinction made as regards cases received for nursing where a sum of money was paid down. Objections have been raised to the inclusion of one-child nurse cases being brought within the protecting arm of the law, but by such an amendment of the present Act there can be but little doubt incalculable good both to the mother and child would accrue. Mrs. Tennant, in Professor Oliver's admirable new work on "Dangerous Trades," indicates the dangers arising from the present system of employing young women in factories. In only too many instances the neglected infant of the one generation becomes the neglecting mother of the next. "For the girl-children full escape seems impossible. Victims in their ignorance of home, they become vehicles to perpetuate the system; without knowledge of the sacred, the helpful, even the elementary elements of home life, they in their turn, in their own married life, seek mill employment as did their mothers before them. It is, in fact, the only occupation they know. Baking, washing, sewing, are dead arts; and in these, children of mothers to a grievous extent denaturalised towards their offspring, the deepest forces of Nature seem asleep. So from generation to generation the service of the mother to her child is entrusted to a stranger, whose introduction as substitute housewife, substitute mother, is not without its cost. The net gain is sometimes in money—a few shillings; in influence and training there is always a loss." The protection of infant life is a matter of the highest national importance. Various aspects of the subject are referred to in the papers we have mentioned, and those of our readers who are interested in this interesting and most practical branch of sociological work would do well to peruse them.

FIRE RISKS AND THEIR PREVENTION.

The preservation of life and property against the risks of fire is clearly one of the most important of municipal duties. As we have previously pointed out in the columns of the Medical Press and Circular, the question is one of peculiar interest to the medical profession by reason of the numbers of helpless patients who are brought together in our sick hospitals and infirmaries. It is terrible to think what would be the result should a great fire break out in any large institution of the kind in the United Kingdom. There are various ways of minimising the spread of fire in a building, such as the use of fire-resisting materials, a proper construction and the provision of exits available for all parts and all levels of the structure. The recent coroner's inquiry into a fatal fire in the City of London, an occurrence in which six or seven lives were lost in broad daylight, as the result of a comparatively insignificant fire in the heart of the City, showed on evidence that the fire escape first brought to the scene of the fire on that occasion failed to reach an ordinary fifth floor, under sixty feet in height. Had the escape reached that window it is absolutely certain that some, if not all, of the unfortunate victims would have been rescued. A long fire ladder or escape was ultimately brought and two persons were rescued by its means. It is therefore incontrovertible that the loss of life was mainly due to the want of a fire escape long enough to reach a fifth-floor window. An important fire station lay about a hundred yards from the fire, but it possessed only a short escape. For years the inadequacy of that fire station to the needs of the district had been notorious, and had formed frequent subject of comment and debate, but the fact remains that the station stands now at the present moment just where it did a dozen years ago in point of size and efficiency. Under such circumstances the failure of the London County Council as the central fire authority of the Metropolis to provide adequate life-saving appliances and organisation seems to be fairly well established. With their alleged similar failure in their fire-extinguishing function we are not here concerned, although the enormous advance in fire insurance rates of recent years affords some indication of the way the wind is blowing. Under these circumstances the report of the London County Council, which is the fire authority of the Metropolis, dealing with the recent fatal fire, has been looked for with an unusual amount of interest. The result has been somewhat remarkable. A report has been issued by the Council, not only exonerating everyone all round from blame, but actually exalting the efficiency of the Brigade and of all appertaining thereto. The report, in short, is adulatory as well as whitewashing. It is of that order that is so sensitive of criticism that it expresses its resentment by proving that black is white, and that the defence is not only blameless but aggressively virtuous. As a matter of fact, it is the last type of documentary defence we should have expected from an enlightened and progressive body such as the London County Council. By its extreme attitude it is far more likely to lower the popular estimate of the candour of the Council. No amount of whitewashing casuistry on the part of a responsible committee will persuade the public that the fire-escape at Queen Victoria Street should not have been long enough to reach a fifth-floor window, or that it is right that the premiums on City property should have advanced 50 or 100 per cent. within a few years. It would be far wiser for the County Council to acknowledge their imperfections and to promise better things in future than to attempt to defend the indefensible with specious reports.

BOVINE TUBERCULOSIS.

Professor Koch has once more asserted his belief in the innocuousness of bovine tuberculosis to the human being. Few men are better entitled to a patient hearing on the subject than the distinguished scientist, and he is all the more deserving of consideration from the fact that his view on the question is not the popular one. Briefly stated, Dr. Koch does not base his argument so much on bacteriological grounds as on that of common experience. It is common knowledge that cattle in the state of domestication are very subject to tuberculous disease, and that in them the disease tends to become generally disseminated—bone, muscle, and gland tissue, all suffer, and the majority of cattle in herds, even under most favourable conditions, become infected with the disease to a greater or less extent. The flesh is eaten and the milk drunk of such animals without any marked evidence of its transmitting the disease. There is not, however, perfect immunity to the user of the milk or flesh; nor does Koch claim absolute immunity, for he states that he has collected twenty-eight cases of transmission of the disease to man. The danger of human infection is, probably, greatest when the udder of milch cows is affected, and the milk of such animals should be declared unfit for sale. Happily, the udder is not often tuberculous, and when it is the disease is easy of recognition. Nocard, who examined a hundred diseased cattle, found tubercle in the lung and pleura in forty, in the lungs alone in twenty-five, and in the serous membranes in twenty; the lesions in the remainder being generalised or located in the lymphatic ganglia, the genital organs, the osseous system, or other parts. The characteristic bacilli have not infrequently been found in the fluid expressed from infected muscular tissue; they have also been observed in the blood and in the secretions of diseased organs. Cooking does not render such meat sterile, as Woodhead's experiments have shown, and in this connection it is well to remember that roasting was the least and boiling the most effective method of destroying the bacilli. Woodhead, however, took no notice of the sterilising power of the intestinal secretion, which French bacteriologists have shown has an antiseptic power of great value. The question is not one of yesterday. In 1888 the French Government forbade the sale of tuberculous meat: (1) If the lesions were generalised; (2) if the lesions though localised, had invaded the greater part of an organ, or were manifested by an eruption on the walls of the chest or of the abdominal cavity, such flesh was not to be used even for feeding animals. In Austria when the disease is localised the remaining meat is passed as healthy. On the other hand, in Russia the presence of tubercle, even though localised, is looked on as rendering the whole carcase unfit for food. This Russian edict is, however, never enforced when the extent of the disease is small; indeed, its enforcement would mean the total or almost total prohibition of animal food in European Russia. We may just mention the interesting fact that although wild animals are, as Paget long since showed, subject to many of the diseases of domesticated ones, nevertheless, tuberculosis is unknown in wild animals of the bovine species. The wild cattle of Chillingham know it not; it has not been found in the Yellowstone Park; and among the many thousands of herds of bisons that roamed from the Canadian lakes to the Gulf of California it was never once seen. In the partly domesticated herds of Uruguay and Argentina it is practically unknown; while in cattle, as in man, it is a disease of modern civilisation.

Notes on Current Topics.

An Anti-Alcohol Maniac.

THE injury done by fanatics to the cause they espouse, as all the world knows, is often great, and sometimes deplorable. This is, perhaps, more true of temperance advocates than of any other class of social reformer. Alcohol is the red rag that goads them to fury, and they push the principle of total abstinence from alcohol to the most far-reaching and illogical lengths. For instance, they forbid all medicines that contain alcohol, a step that at once excludes many valuable remedies, such as the tinctures, which in most cases represent the only form in which the active medicinal virtues of the drugs concerned could be rendered available as physic. The most serious of all these prohibitions, however, is probably that which prevents the use of alcohol as a medicine. While the average medical man must agree cordially as to the immense evil wrought by excessive indulgence in alcohol, he will almost invariably, even when a total abstainer himself, endorse the value and necessity of alcohol as a stimulant drug. Certainly the medical practitioner who foreswore the use of alcohol would in that way permit many a patient to slip through his fingers. In case of shock alcohol is by far the readiest and most powerful weapon in the hands of the medical attendant, who would stamp himself as either a fool or a fanatic, or both, should he refuse to avail himself of the stimulant action of alcohol when brought face to face with the kindred conditions of shock, faintness, and syncope. Bearing these facts in mind, it is with mixed feelings of amusement and pity that we find a notorious American temperance advocate, Mrs. Carrie Nation by name, pushing her extreme views to a practical issue in the midst of the havoc and confusion of a railway collision. We are told that recently an express train was wrecked by running into an engine just outside Jersey City, and that a number of passengers were seriously injured, one being transfixed by an iron bar. As soon as she recovered herself sufficiently from the shock, Mrs. Nation's first thought was to prevent the sufferers from drinking the brandy brought to them by the doctors. We are told that this deluded woman actually "broke several bottles containing the hated liquor." The force of fanatic folly could hardly further go. The incident is typical of the shallow intellectual equipment of the extreme temperance agitator. All reasonable men and women would doubtless regard Mrs. Carrie Nation as a most undesirable fellow-passenger in a railway smash. It is clear enough that by stopping the administration of brandy under such circumstances any number of unfortunate sufferers might lose their only chance of surviving the first shock of the accident.

The Moderate Drinker.

THE study of inebriety reveals a well-marked disease passing through various stages which are perfectly recognisable by experienced observers. Certain groups of symptoms can be found in most cases which may be termed pathognomonic, and these will be seen in the later stages more fully developed. The incipient stage, *i.e.*, before spirits are resorted to, is often marked by dietetic peculiarities and other symptoms of cerebral irritability One of the most remarkable mental peculiarities of chronic alcoholism is the firm belief of the victim in his ability to stop at will, and this is almost as well-marked in the moderate drinker. A certain proportion of moderate drinkers remain in this stage during life and placidly assume that it is owing to superior will power that they do not lapse into chronic inebriety, whereas it is often merely a question of circumstances and occupation. That there is a neurotic element in these cases is suggested by the fact that a predominant feature of the mental state is a craving for excitement of some kind. If that craving be satiated by other means then respite is obtained, otherwise alcoholic stimulation almost fatally follows. We are gradually getting rid of the old view that inebriety is due to wilful wickedness; we are getting to recognise that alcohol is to the nervously irritable what hypnotics are to the sleepless—a palliative remedy, but one which is worse than the disease. The study of inebriety is a most interesting department of psychology on condition that it is studied dispassionately. Unfortunately, many specialists in this branch display extraordinary bias, and weaken their deductions by assumptions which are not justified by common experience. We are told, for instance, that the moderate drinker "transmits to the next generation a weakness that is sure to appear in the form of one of the allied neuroses." Such a statement carries its own refutation, for where should we all be if it were true. Our ancestors, or many of them, were, to put it mildly, moderate drinkers, and we ought, therefore, all to be suffering from "one of the allied neuroses." It is difficult to define exactly what constitutes a moderate drinker. We would suggest that the appellation should be restricted to those who never indulge in alcoholic beverages except at meals. Thus defined their number would be small, and there would be less uncertainty as to what constitutes moderation.

A Barber's Shop as a Small-pox Centre.

The desirability of more complete control over certain shops, such as those of barbers, milk-sellers, and publicans, is being constantly forced upon the attention of sanitarians. As regards small-pox, the prevalence of epidemics in various parts of the United Kingdom renders a recent occurrence at Nelson, in Lancashire, of more than usual interest. It was proved in the magistrates' court of that place that deceased had lately suffered from small-pox, that his wife and daughter were suffering a month later from the same disease, but no medical man had been called in, and no notification made, while business had been carried on at the defendant's premises during the whole period of infection. As a consequence of this state of affairs the shop became an active centre of infection before it was discovered by the sanitary inspector, who traced no less than fourteen cases of small-pox to that source. After much trouble the official in question found out that the barber had been ill about a month previously, and still bore the discolorations of small-pox on his face. The defendant declared he was not aware of nature of his illness and could not afford to pay a doctor. He attributed his illness to the bad smell of a fish shop. The flimsiness of this defence, which clearly did not exonerate the defendant from seeking charitable medical advice for so much serious illness in his household, and from thereby learning the nature of the complaint, was recognised by the bench in their extremely lenient fine of twenty shillings and costs.

Women and Water.

An interesting discussion has recently been proceeding in the lay press on the likes and dislikes of women for water as an agent for personal cleansing. Mere man, generally speaking, is not devoid of aquatic instincts. Bathing is one of the delights of boyhood. The average Englishman of the upper classes suffers much discomfort if deprived of his morning tub. Most middle-class homes, and indeed, in some towns, the habitations of the superior labouring class, are provided with excellent baths. The baths provided in such resorts for the poor as Lord Rowton's lodging houses are excellent. And now municipal enterprise in most large towns has provided admirable swimming baths and wash-houses. Yet, in spite of a growing sense of the importance of cleanliness as being in very truth next to godliness, it is contended that women still remain bound in the old fetters of superstition and ignorance regarding the danger of bathing. It is regarded as a serious risk to wash the head; and the dangers of "chills" and "colds" and "congestions" still frighten the uninstructed. The idea that a cold bath is injurious during menstruation, pregnancy, and lactation still lingers. While the women of the upper class have readily learnt from their masculine fellows the advantages of water, and are now often proficient swimmers and regularly enjoy the morning dip, females of the middle and lower class make but little use of the baths available in their own homes, and but rarely visit the public swimming baths reserved for their use. In most households absolutely no arrangement is made for the regular use of the bath by the servants, although on hygienic and all other grounds the thorough cleanliness of those who serve us should receive the greatest attention. During the last few years the importance of fresh air is being strenuously enforced, and there are signs that some awakening of the general intelligence has been obtained; it is now surely time that people should be taught that water both externally and internally is an essential element for the maintenance of a high standard of health.

Puerperal Eclampsia.

The etiology of puerperal eclampsia is one of the many problems that is ever before the physician, and is one full of interest. For years, indeed, until ovariotomy became a recognised operation, the theory was that the disease was caused by pressure of the gravid uterus on the renal vessels. Laparotomy, by demonstrating that pressure from abdominal tumours was not followed by eclampsia, was fatal to the theory. A fresh theory, and one supported by a considerable body of evidence, comes to us from Russia, where Professor Stroganoff noticed in the St. Petersburg Midwives' Institute a series, or rather a number of series, of eclampsia, and, on the grounds that none of the many existing theories would reasonably account for the cases, he began to suspect that the disease was infectious, and commenced an analysis of recorded cases, the most important of which were Olshausen's series, eleven in number, comprising eighty-three cases, and Zwiefel's (*Ber. Klin. Woch.*, 1878) records of twenty series. He concludes that the disease is caused by an air-borne contagion, which infects the patient through the respiratory tract. The disease usually takes six days to develop, is only slightly virulent, and infects neither children nor men, and women are not susceptible to it except during the puerperium. The theory is worth consideration.

The Preparation of Museum Specimens.

No one can visit the various pathological museums in London and elsewhere without feeling that much time and expense have been expended in the collection and preservation of valuable specimens, and yet, in consequence of the methods adopted in their preparation, only limited success has been secured. Marked improvements have been noticeable in recent years, and the introduction of the formalin method has done much to preserve the natural features of specimens. But much advance needs to be made before it can be said that altogether satisfactory results have been attained. Hence all experiments in this direction are worthy of careful consideration. Dr. Harvey Littlejohn, of Edinburgh, in the current number of the *Journal of Pathology*, says the preparation is first subjected to Kaiserling's method of hardening: After washing away adventitious blood, the specimen is immersed in formalin solution. It is then placed in pure methylated spirit until the original colour returns. It is then removed to a glycerine and water solution to which a little formalin has been added. After being thoroughly impregnated with glycerine the preparation may be removed to a jar and securely covered as a "dry" specimen. The specimen should be laid upon absorbent wool, and before the jar is sealed about an ounce of pure glycerine, mixed with a little formalin, is either placed underneath the wool or poured over the surface of the preparation as it lies in position. The interior of the jar must be air-tight, and ordinary glazier's putty is effectual in sealing the cover. Dr. Littlejohn has employed his method for five years, and is very pleased with his results. We shall be glad to hear the views of other practical pathologists as to the utility of this procedure.

Honour to a Physician.

The Commonwealth of Georgia has voted 7,000 dols. for a statue to be erected in honour of Crawford Williamson Long, the discoverer of general anæsthesia, in the Hall of Fame, in the Capitol, Washington, D.C., U.S.A. Each State in the Union is entitled to erect two statues in the Hall, and the selection of the names of those most worthy is one in which great care is exercised. As yet Georgia is unrepresented, and although the Commonwealth had resolved to honour Crawford W. Long, the necessary money vote was deferred until his claims to the honour of discovering general anæsthesia were placed beyond doubt. Of those who took an active interest in examining the evidence adduced in favour of the many candidates for the honour were Dr. Luther B. Grandy, who died recently in the Philippines, whilst in charge of the U.S A. troops; Dr. Landon B. Edwards, who obtained from Georgia evidence from authoritative legal documents of the Supreme Court of the Commonwealth, and from living, trustworthy witnesses; and Dr. Marion Sims, whose paper appeared in the *Virginia Medical Monthly*; and Dr. George Foy, who exhibited the proof of Dr. Long's original paper to the Society of Anæsthetists in London, by favour of Dr. Luther B. Grandy, of Atlanta, Ga Dr. Long was by descent an Ulster man, his father having left Letterkenny, co. Donegal, to which the family belonged, in the eighteenth century. In 1861 Dr. Long enlisted in the Confederate States service and was appointed surgeon to the base hospital at Athens, Ga., where he was engaged until the capitulation of General J. E. Johnson at the termination of the Inter-States war

Bournemouth Medical Motorists.

Nowhere, perhaps, are the advantages of the motor car as a means of locomotion as widely appreciated by members of the medical profession as at Bournemouth, where, judging from recent accounts, it must be the exception for patients to be visited otherwise than in one of these unduly self-assertive vehicles. Instead of the odour of iodoform with which antiseptic surgery has imbued the practitioner, he now brings with him an agreeable odour of benzine, which, low as it ranks in the list of perfumes, will doubtless be preferred by many to the pharmaceutical emanations of ancient times. A collateral advantage attending the use of a motor car in this southern health resort is the appearance of portraits of the envied possessors in the current number of the *Autocar*.

Medical Political Influence.

Our contemporary *Truth* appears to be firmly convinced that the medical profession commands sufficient influence in Parliament to secure the promotion of any bill they may think fit to introduce, having for object to impose salutary restrictions on the sale of nostrums and to check the fraudulent misrepresentations of quacks. Of course it is open to any section of the community to *promote* a bill for this or any other purpose, but between promotion and adoption there is a great gulf. Did the profession rejoice in such power there would long since have been no occasion for *Truth* to hurl well-deserved and pungent adjectives at the proprietors of the Viavi humbug or the Drouet delusion. As a matter of fact we are unable to obtain the power to inhibit the practice of medicine even by unworthy members of the profession whose names have been removed from the Medical Register for infamous conduct, and the greatest difficulty is experienced in obtaining the conviction of the grossest offenders against the laws regulating the practice of medicine. The State reaps a rich harvest levied on the depredations of the unscrupulous vendor of proprietary nostrums in the shape of the Medicine Stamp Act, and shows the greatest disinclination to forego a source of revenue which is distinctly immoral, and is a tax levied on the sick. The continued existence of the various quack abominations against which our contemporary has so long lifted up its voice is evidence of the gullibility of the public and the indifference of the legislature.

The Contract Practice Struggle.

Under the heading of "Doctors' Trades-Union" the provincial newspapers chronicle the various episodes in the general movement for increased rates which is in progress throughout the length and breadth of the land. Low as are the average rates for club and contract practice, there are districts in which even lower rates obtain, and the first move is in the direction of bringing the minimum rates into line with the normal. Later on, no doubt, attempts will be made to increase the general rates in proportion to the rise of wages which has taken place in all industries during the last fifty years. As to the outcome of the movement, there need be no anxiety, and we are justified in hoping that in the vast majority of instances the increase will be conceded after consultation and due deliberation. Working men, however reluctant to pay higher rates for medical attendance, are, if properly handled, not impervious to reason, and, when they prove otherwise, a little gentle pressure will convince them of the reasonableness of the demands formulated by the medical officers of their friendly societies. It is a noteworthy fact that the greatest opposition comes from members of the great trades-unions, but this may be explained on the ground that in virtue of their membership they feel better equipped for resistance.

Suicidal Aeronautics.

The minds of the aeronautical fraternity have been much exercised by recent mishaps in the manipulation of airships, and, judging from the discussion which took place last week at the Aeronautical Institute, it is felt to be imperatively necessary to impose certain restrictions upon inventors before allowing them to raise themselves above their fellows. It was suggested, for instance, that only certificated aeronautists should be authorised to take charge of a flying machine, any accident occurring at the hands of any uncertificated persons being punishable by fine or imprisonment. One speaker, indeed, urged that he should be treated like an ordinary homicidal or suicidal lunatic. Had such laws been in vigour in Montgolfier's time he would infallibly have got "six weeks' hard" for making a fool of himself in his fire balloon, nay, the inventors of the steam locomotive were formally accused by the Press of their day of wilfully endangering tho lives of their fellow-citizens. Even the cyclist who daily threads the maze of London traffic at his risk and peril would fall within its scope; in fact, no enterprise of pith and moment would be possible if, to speak allegorically, every person were compelled to produce evidence of knowing how to swim before being allowed to enter the water. A life lost in the advancement of knowledge is not wasted; it is a sacrificial offering on the altar of science calling for public recognition and admiring sympathy.

The Prognosis of Death.

Considerable interest attaches to the cause of death in persons who have recently insured their lives, if only because it shows how fallible are even expert opinions on the "prospect of life." The medical officer of one of the largest life insurance offices of the United States, in a recently published report, states that of 2,375 deaths of insured in 1901 ninety-five took place within a year of the issue of the policy. Casualties accounted for nineteen, pneumonia for eleven, and consumption for seven, while heart disease and typhoid fever took nine each. Four succumbed to meningitis, and five to appendicitis, while three died of apoplexy and six of cancer. Two died of renal affections and the remainder of more or less fortuitous diseases. Of course, none except a fortune-teller could foresee typhoid fever apoplexy, or death from accident, but what must we think of consumption, cancer, and heart disease? Even appendicitis is not as accidental as it may appear at first sight, since it is infinitely probable that some, at any rate, must have had previous attacks, and we presume no medical examiner would accept the proposal of a person who had suffered from non-operated appendicitis. It would be interesting to compare a hundred deaths within a year of insurance in this country with the above list, for it would afford some ground whereon to institute a comparison between the diagnostic ability of the medical officers of life offices on this side of the ocean. The very large proportion of early deaths from accident gives prominence to the life-cost of modern machinery and appliances, but it is impossible to appreciate its exact significance without knowing precisely the social status of the victims.

The Ubiquitous Reporter.

The reporter is a necessary evil in these days of cheap journalism, and he must be borne with when he cannot be repelled. Yet there are certain places and circumstances in which public opinion unhesitatingly declares him to be *de trop*. Among them is the room in which a post-mortem examination is being performed for medico-legal purposes. Very properly did the judge in the Ipswich murder case animadvert on the presence of a reporter while the autopsy of the victim was being made, and one would like to know in virtue of what occult protection he was admitted—for he could hardly have been present by chance or by mere negligence. The judge promised to take cognisance of the paragraphs in the newspaper containing the allusion to this part of the investigation. and to deal with them *sec. art.* We are surprised that the medical men engaged in the case did not "spot" the intruder and have him ejected. Of one thing we may be sure, that no medical sanction was given to his unwarrantable intrusion.

The Standardisation of Drugs.

There exists, as most of our readers are probably aware, an official compilation known as the British Pharmacopœia, the object of which, *inter alia*, is to formulate certain tests of purity and methods of preparation having for object to ensure as far as possible the uniformity of preparations for medicinal use. Unfortunately, no provision is made to ensure uniformity of physiological action and therapeutical effect on the part of these products, effects which vary within extraordinarily wide limits, even when the technical directions contained in the official programme are rigidly adhered to. This is a fact which must be familiar to all practitioners, especially those who, dispensing their own medicines, are better able to observe their action. Mere titration of the principal alkaloidal ingredient of a drug does not fulfil the desideratum, since the chief constituent does not necessarily represent the whole activity of the drug. It is not for us to suggest the ways and means by which this object might be attained, that being a purely technical matter with which the pharmacopœial committee must be left to deal, but that there is room for reform will be seen from the paper read by Mr. Wippell Gadd, an abstract of which we publish elsewhere. The matter was fully discussed at yesterday's meeting of the Pharmaceutical Society, when various suggestions were made with this object in view. These we shall deal with more fully later.

Uterine Fibroids and the Menopause.

It is odd that there should be so much difference between experts on such a simple question as the tendency to disappear of uterine myomata after the menopause. The belief that such a tendency exists is so general, and has received such authoritative sanction, that it is formally recognised in every text-book, and is held by many surgeons to justify an expectant attitude in presence of uterine hæmorrhage due to fibroid when the age of the patient is such as to allow the advent of the climacteric period to be awaited. The structure of uterine fibroids or myomata is indistinguishable from that of the uterus proper, and one would naturally expect it to share in the atrophy which overtakes that organ at this period. Moreover, there is ample evidence to show that fibroids which have grown very rapidly during pregnancy have retrogressed with equal rapidity along with the uterus during the process of involution. There are few gynæcologists who cannot recall instances of fibroids which have at one time given trouble and have subsequently shrunk to such an extent as to become inaccessible to examination. Altogether one appears justified in accepting this view as correct; yet, in Mr. Bland-Sutton's opinion, it is "pure superstition." It is a pity that such an important point should be left undecided, seeing that it would be within the power of a small committee of the Obstetrical Society to settle it once for all. It is not asserted that all fibroids evince this tendency, and possibly this may depend in great measure upon the proportion of fibrous tissue which enters into the composition of the growth. One would expect those in which muscular tissue predominated to be more apt to undergo shrinkage than hard, fibrous growths, but whether this is the case cannot for the present be stated. In view of the important bearing which this question of spontaneous shrinkage has upon the adoption of surgical treatment, it is highly desirable that it should be cleared up, and we would suggest the matter as suitable for general discussion at one of the medical societies.

The New York Medical Society has succeeded in obtaining the conviction of a local clergyman for the illegal practice of medicine. The reverend gentleman had for three years past been advertising a cure for the drug habit, and had organised a committee to collect subscriptions to defray the cost of the treatment for indigent patients.

Bubonic Plague.

Dr. Bruce Low's report on bubonic plague has been presented to the President of the Local Government Board, England. The report will remain of historical value as the most exhaustive and clear pronouncement that has yet appeared on the disease. He has not only recorded chronologically and topographically all recent manifestations of plague, but he also indicates in each instance the source of the malady, the dimensions of the plague prevalence, its fatality, and the measures adopted with regard to it. Not the least valuable feature of the report is the section dealing with the confusion of the bubonic plague with other maladies, usually some commonplace current malady, as, for instance, influenza, enteric fever, malaria, and the like. But so often has confusion thus arisen as almost to suggest mimicry, as it were, by plague, on first transplantation to a new soil, of indigenous maladies. The report adds that notwithstanding the facilities afforded to the plague in dense populations of fastening on a number of localities presumably prone to foster it, this disease has seldom become quickly or largely epidemic. In this respect differing from cholera, such a marked difference in the infectivity of the two diseases offers an interesting subject of study to etiologists and epidemiologists, and gives the sanitarian a reasonable hope of being able to prevent the spread of, if not to completely stamp out, bubonic plague.

Abuse of Medical Charities.

A medical man, who, by the way, signs his full name, qualifications, and address, has recently written a long letter to the *Western Daily Press* (October 14th) on the subject of hospital abuse. He quotes figures showing that some 125,254 persons were relieved during the year 1901 by the Bristol medical charities. Upon that basis, taking the population of the city in question at 130,000, he estimates that one in every two and a half of the entire population of Bristol get relief from the medical charities in times of sickness; and one in every five and a-half die in charitable institutions. There is no evidence furnished as to any attempt to exclude persons coming from other parts from Bristol hospitals, a fallacy that is of the utmost importance in view of the prominence of Bristol as the chief town in the west of England. Otherwise the proportion of the figures suggesting that out of 130,000 citizens no less than 125,000 receive medical charity in the course of the year would be amazing and incredible. Allowing for all sources of error, however, the case of the writer would, nevertheless, be proven by an immense margin of material evidence. Sooner or later this pauperising abuse must be recognised by the philanthropic public who support the charities. We agree with the writer whose letter we have quoted, in his view that the time has come for making a united protest against hospital abuse, inasmuch as thrift is discouraged, self-respect is impaired, and the people are demoralised thereby. And, it may be added, an honourable profession is defrauded of a just and legitimate means of livelihood.

The Female "Dosser."

ACCOMMODATION for London's female vagabonds is meagre. The homeless women of the metropolis have too long been neglected. From a recent return of registered common lodging-houses in London we find that there is accommodation for 2,725 women, and of these 2,151 beds are for single women and 574 beds for married couples. We learn from Dr. Shirley Murphy that the London County Council, as we think very rightly, has discouraged houses allowing accommodation for single persons of both sexes and "doubles." It would seem also that the provision at present existing for females is generally inferior to that available for men, particularly as regards kitchens and lavatories. We are glad to see that it is proposed shortly to provide a municipal lodging-house for women.

Society for the Study of Disease in Children.

A SPECIAL meeting of this Society is to be held in December for the discussion of "Tuberculous Peritonitis." The subject is one of very great interest and importance, and communications bearing thereon have been promised by Dr. E. Cautley, Dr. James Barr (Liverpool), Dr. Theodore Fisher (Bristol), Dr. G. A. Sutherland, Dr. Leonard Guthrie, and Mr. W. Watson Cheyne.

PERSONAL.

LORD STRATHCONA will take the chair at the November dinner of the Aberdeen University Club on Friday, the 19th inst.

DR. R. H. ADERS PLIMMER has been appointed Grocers' Company Research Student at the Jenner Institute of Preventive Medicine.

DR. WILLIAM HUNTER is to take the chair at the dinner of the Edinburgh University Club at the Criterion Restaurant this (Wednesday) evening.

SIR WILLIAM J. COLLINS will deliver a lecture on "The Housing Question in London" before the King's College Medical Society on Friday next, at 8 p.m.

SIR GILBERT PARKER, M.P., will preside at the dinner which is to be given to celebrate the jubilee of Trinity College, Toronto, at the Hotel Cecil on Monday next.

DR. E. S. BASHFORD, assistant to Sir Thomas Fraser, F.R.S., of Edinburgh, has been selected for the post of Superintendent of Cancer Research, and will enter upon his duties forthwith.

Alleged Assault.

MR. WILLIAM RIDDELL MATTHEWS, of Brooks Bar, Manchester, appeared at the County Police Court, Strangeways, last week, in response to a summons charging him with assaulting a girl, age 16, who had been to his surgery to have a tooth extracted. After the hearing the magistrate declined to express any opinion and committed the case for trial, Mr. Matthews being liberated on his own bail for £20.

BIRTHDAY HONOURS.

AMONG the titular appointments made by the King on the occasion of his Majesty's birthday, we note the following:—

C.M.G.

W. H. W. Strachan, Chief Medical Officer of the Colony of Lagos.

Members (4th class) of the Royal Victorian Order.

F. W. Hewitt, M.D., Honorary Anæsthetist to his Majesty.

Donald James Mackintosh, M.B.

C.B. (Military Division).

Henry C. Woods, C.V.O., M.D., Inspector-General of Hospitals and Fleets.

C.B.

William P. Power, F.R.S., Principal Medical Officer to the Local Government Board.

C.I.S.O.

G. McNaughtan, M.D., Medical Officer Scotch Prison Service.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

SCOTLAND.

[FROM OUR OWN CORRESPONDENTS.]

ENDOWMENT OF MEDICAL RESEARCH IN EDINBURGH.—Mr. T. Francis Mason, of Freeland Lodge, Woodstock, who has recently instituted a research scholarship of the annual value of £200 for the study of the thymus and other ductless glands, has generously given a donation of a similar amount to the Laboratory of the Royal College of Physicians of Edinburgh, to be devoted to the further prosecution of a research on the ductless glands which has already been in progress there for several years, under the superintendence of Dr. Noël Paton. Finding by a domestic bereavement that existing knowledge with regard to the physiology and pathology of these glands is very incomplete, Mr. Mason has taken this most practical means of advancing the scientific study of the subject.

GLASGOW OPHTHALMIC INSTITUTION. — The Post-Graduate Course of Demonstrations on Diseases and Injuries of the Eye was inaugurated last week. There was a good attendance. Professor T. McCall Anderson, who introduced the lecturer, commented on the value of post-graduate instruction. The subject of the first demonstration was "Dimness of Sight in Diseases of the Kidney characterised by Albuminuria."

MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

THE ROYAL INFIRMARY.—Great interest continues to be taken in the formation of a new Board. It will be remembered that the old Board resigned after its scheme for re-building on the old site had been thrown out by a large majority of the trustees. Many members of the old Board were willing to serve on the new one, and a special meeting of the trustees was called to legitimise the election of a new Board at this juncture. A strong committee of trustees was formed, and it was thought for some time that the twenty-one gentlemen nominated by this committee would be elected without contest, so avoiding the trouble and expense of a contested election. The last action of the old Board was to fix the date of the election for November 14th. This decision was adversely criticised by the trustees' Committee, as it made Thursday, November 6th, the last day on which nominations could be received, and thus unduly hurried their movements. The situation was further complicated by the decision of the Women Guardians and Local Government Association to nominate two lady candidates for election to the Board. This raises a question which has not previously been discussed, and which introduces some awkward elements into the contest. The trustees' committee state that the idea was sprung on them too late for the inclusion of ladies in their list of nominations. They approve, however, of the employment of ladies in the government of the Infirmary, and suggest the early formation of a ladies' committee, which would doubtless be represented upon the board of management. It gradually became clear that a contest was unavoidable, and when the nominations were made known it was seen that there are thirty-one candidates for the twenty-one places on the Board. Twenty-one gentlemen are proposed by the trustees' committee; two ladies, by the Women Guardians Association; one lady and seven gentlemen by other trustees. The result of the election cannot fail to be a progressive Board, and one which will push forward the scheme for rebuilding on a new site without undue loss of time.

THE OPEN-AIR TREATMENT OF CANCER.

To the Editor of The Medical Press and Circular.

Sir,—We have heard much lately of the open-air treatment of phthisis. This treatment aims at bringing the vital processes to such a level as will enable the natural and healthy elements of the body to counteract the unnatural or morbid ones. Or, to speak in greater detail, such an array of defensive elements, as represented by leucocytes, lymphoid cells, and giant cells, is created as to destroy or render impossible the life of the offensive ones, as represented by the tubercle bacillus and its derivatives. This result is brought about by a plenitude of fresh air and good food.

I propose to apply these factors to the treatment of cancer. By fresh air I mean such as can be obtained, not on the balconies of a hospital at Brompton, but on a summit of the South Downs for example. By constant exposure to such air and *sufficient* food, and by this I mean as much as will suffice to keep the vital processes at the highest, which necessitates that the patients should be always kept slightly on the "hungry side," such an army of lusty young leucocytes might be created as would turn in hungry desperation on the cancer elements and rend them. I again emphasise the importance of sufficient food, as the advocates of the open-air treatment of phthisis believe and practise the astonishing fallacy that too much food is better than enough. The result is, and must be, that a large proportion of the defensive elements called into existence by the treatment are occupied in combating and neutralising the morbid products of over-assimilation.

That the human body contains or can produce elements capable of destroying, or rendering impossible, the life of cancer elements, is proved by the occasional disappearance, or at least atrophy, of cancerous tumours. Such an undoubted case, as evidenced positively by microscopic examination, was instanced a few years ago in the *British Medical Journal* by a Dublin surgeon. We have all seen how the warts of adolescence disappear of their own accord as the system becomes more stable. Mr. Hutchinson has pointed out that if several of such a crop are destroyed, the rest disappear spontaneously. I can well remember seeing a poor Jewish woman who led a lonely life for many years in the dreadful companionship of an immense and evil-smelling cancer, that had destroyed the left breast, crept under the axilla, and spread over a considerable area of the back. Here, surely, was resistance.

I am aware that cancer occurs on the "hill side" and in the "alley," but always under the same vicious conditions of too much or improper food, and in the latter instance, bad air. Both these factors would be eliminated by what I propose.

I am, Sir, yours truly,
Hope Grant, F.R.C.S.E.

15, Christopher Street, E C.

WHOOPING-COUGH.

To the Editor of The Medical Press and Circular.

Sir,—From what I saw of whooping-cough at the Hospital for Sick Children, Great Ormond Street, when about 3,000 cases passed under my notice, I came to the conclusion that it was impossible to arrive at any clear conclusions as to the nature of the disease from hospital resources. What impressed me more than anything on this point was the account given me by Sir William Jenner of the change in his views regarding the malady after he suffered from it late in life. He confessed that until then he never understood it. Much the same thing happened to Sir Thomas Watson, who wrote to me at the time his son, the present baronet, and his grandsons caught whooping-cough from the younger children.

There is no doubt but that those who work among the poor and see the disease in the crowded parts of a great city can best understand the very singular nature of the malady. It is more fatal to young children than all other diseases combined, for it assumes very different forms, and the symptom of the whoop is a small one among infants. From the time of Ballonius (de Baillou) in 1578, that is, a century before Willis in England described whooping-cough, it was known in Europe. The time has come when its infectious nature and other peculiar characters are being recognised, and the erroneous views entertained regarding the disease are being corrected.

I am, Sir, yours truly,
Robert Lee.

DENTAL ANTISEPSIS.

To the Editor of The Medical Press and Circular.

Sir.—With reference to your editorial note to-day (Nov. 5th), I would like to point out that every dental surgeon who performs the more delicate operations of his profession is, so to say, bound over to the practice of strict antisepsis. If he disregard it the vast majority of his operations will turn out unsuccessful. For example, in manipulating the canals of roots, if nerve-extractors and other such instruments be not sterilised and strict antisepsis observed throughout, the danger of exciting acute alveolar abscess becomes extreme; and a patient going about with a badly swollen face as the result of an attempt to save a valuable tooth, which after all may have to be drawn, forms about as bad a walking advertisement as a practitioner can make for himself. Such accidents do not happen unless as comparatively rare exceptions under the hands of those who practise strict antisepsis. Similar remarks apply to extraction. Every dental surgeon knows that foul forceps may set up local sepsis or even give rise to much more serious distant effects; and as the trouble of keeping instruments clean is really small, it must be an uncommonly careless practitioner who neglects it. Among a certain class of practitioners and "tooth drawers" complete disregard of antiseptic precautions is too commonly displayed. Cases exemplifying this are to be found in numbers at the dental hospitals and dental departments of general hospitals. Every now and again cases of death following tooth extraction are reported. Two of such cases within the past few years have been under my own notice. The tooth in each case had been drawn by an unqualified practitioner. An inquest in each case was held, and the medical evidence proved the deaths to be due to septicæmia, the result of infection of the alveolar wound. Comment was made upon the rough and filthy condition of the instruments which had been used. It is customary to make light of dental diseases because they do not commonly directly or indirectly involve danger to life; but every dental surgeon in active practice has daily brought home to him the fact that these diseases inflict in the aggregate a terrible sum of physical misery. It is not to be expected that a Legislature which refuses to protect the health and lives of the simple public against the wiles of the most infamous and blatant medical quack, will interfere in the case of the fraudulent dental pretender, who if less harmful, is so only because his scope for evil is more limited.

I am sir, yours truly,

November 5, 1902. M.R.C.S., L.D.S.

Obituary.

LENNOX BROWNE, F.R.C.S.Ed.

The death of Mr. Lennox Browne, which took place at Frith Lodge, Northwood, Herts, on Sunday, November 2nd, from malignant disease ot the stomach, marks the disappearance of a striking personality from among metropolitan specialists. Mr. Lennox Browne had attained a well-recognised position in his special department of practice, and if he did not perchance occupy quite that to which his skill and experience appeared to entitle him it was due to the fact that his energies, indefatigable as they were, were too diversely employed. From his youth upwards Mr. Lennox Browne displayed remarkable artistic proclivities, and his water-colours are highly prized, not only by his friends who were fortunate enough to become the recipients thereof, but also by the more censorious public who paid for them. This talent he turned to excellent account in the pictorial representation of morbid appearances of the throat and nose, and the coloured drawings which grace his *magnum opus* on "Diseases of the Throat, Nose and Ear" greatly enhance the value of a treatise which for many years was the most authoritative text-book on the subject. Mr. Lennox Browne was sixty-two years of age at the time of his death, and he qualified in 1863. After a brief sojourn in Australia he fell in with the late Sir Morell Mackenzie, with whom he remained in close literary association for upwards of seven years, during which period he illustrated Mackenzie's essay on "Growths in the Larynx." He was mainly instrumental in the foundation of the Central London Throat and Ear Hospital, which was opened in 1874, and he only retired from the active staff two years ago, when he was appointed Consulting Surgeon.

Mr. Lennox Browne was combative and masterful by nature, and this too marked individuality created for him numerous enemies, many of whom were admittedly of his own making. He, however, possessed remarkable organising qualities, and his assistance was highly prized by his colleagues at the Central Hospital, the interests of which he always had at heart. On two occasions his services were formally recognised, first on his fiftieth birthday, when they presented him with a handsome silver bowl, and again on his retirement from the active staff, when he was presented with a suite of old English furniture for his country house and an illuminated address. His residences, both in town and country, were full of charming drawings and pictures, many of them signed by the best-known names in the artistic world.

Mr. Lennox Browne was the son of Dr. Isaac Baker Browne, at one time well known in the obstetrical world, and one of the pioneers of ovariotomy in England, and this at a time when much opprobium was wasted upon those who advocated a departure in surgery, which was not put on a sound basis until Sir Spencer Wells brought his master mind to bear upon it and shamed professional opinion into acquiescence. He bore his severe sufferings with the greatest fortitude, seeing patients as recently as September 16th, and he continued to interest himself in his garden and in artistic pursuits until only three weeks since, when his condition obliged him to take to his bed.

He was the author, among many other works, of "The Throat and Nose and their Diseases," which reached a fifth edition, and is still unique by reason of the beauty and fidelity of the illustrations; this was translated into French in 1891; "Diphtheria and its Associates" (1896); "Deformities and Morbid Growths of the Pharynx and Larynx," and, with the late Mr. Emil Behnke, he published a work on "Voice, Song and Speech," which ran into eighteen editions. When the serum treatment of diphtheria was introduced Mr. Browne published several papers adversely criticising the results claimed for this treatment, but, although they attracted a good deal of attention at the time, universal experience has since shown that his arguments did not repose on any solid substratum of fact.

He was a prominent Freemason, being a Grand Officer of England as well as of the Grand Lodge of New Zealand, and he was one of the oldest living members of the Savage Club.

He was buried at Northwood Parish Church on Wednesday last, the ceremony being attended by his hospital colleagues and members of the committee of management and a number of friends. *Requiescat in pace.*

Laboratory Notes.

NEW TABLOIDS.

Additions to the list of "tabloid" products manufactured by Messrs. Burroughs Wellcome and Co. are so numerous that, in spite of their individual interest, it is difficult to keep abreast of the tide.

Among recent additions to the list of "tabloid" ophthalmic products we note atropine sulphate gr. $\frac{1}{800}$. This is readily soluble, and is intended to be introduced directly into the conjunctival sac, when it promptly produces the characteristic effects. In view of the ease with which solutions of atropine undergo decomposition when kept this method of oculotherapeutics presents obvious advantages.

"Tabloid" Aspirin, gr. v., is a convenient form in which to administer this substitute for salicylic acid and the salicylates. Aspirin is an acetyl-acetic acid, and is recommended in the treatment of articular rheumatism, &c. The dose is from 5 to 15 grs., repeated several times in the twenty-four hours.

The "tabloid" Apomorphine compound contains gr $\frac{1}{50}$ of apomorphine in combination with chloride of ammonium and liquorice. The expectorant action of the alkaloid is thus reinforced by the stimulant action of the ammonium chloride, and the demulcent properties of the liquorice. They are directed to be allowed to dissolve in the mouth, but having tried one we recommend that they be swallowed *subito* before the ammonium chloride has time to reveal itself in solution.

The "tabloid" of Yellow Iodide of Mercury contains a definite chemical salt, free from metallic mercury, and is, under ordinary circumstances, perfectly stable. Each tabloid contains gr. $\frac{1}{8}$ of the salt.

The "tabloid" of Compound Liquorice Powder contains 30 grs. thereof in compressed form, and affords a very convenient means of administering an otherwise disagreeable preparation.

The "tabloid" Kino Compound Powder contains 5 grs. of the official preparation, which is a well-known and trustworthy sedative-astringent in the treatment of irritative diarrhœa, dysentery, &c.

HYPODERMIC SUCCINIMIDE OF MERCURY TABLOID.

These products contain gr. $\frac{1}{5}$ of hydrargyrum succinimidum, and are designed to facilitate the hypodermic treatment of syphilis and syphilitic manifestations. Injected well into the muscles this salt gives rise to but trifling local reaction, thus rendering possible a very efficacious method of treatment, the only objection to which, when certain other salts of mercury are used, is the pain following each injection.

SOLOID MICROSCOPIC STAINS.

It is certainly a happy idea to put up current stains for microscopical work in "soloid" form, thus facilitating the preparation of fresh solutions containing a well-defined proportion of the ingredient. "Soloid Microscopic Stains" are issued in packages of six. The full list comprises: Soloid Bismarck brown, borax, methylene blue, eosin, eosin methylene blue (Louis Jenner), fuchsine, gentian violet, Gram's iodine solution, hæmatoxylin, hæmatoxylin (Delafield), methylene blue, methylene violet, and thionine blue.

"JENULE" OF MORPHINE AND BELLADONNA.

This suppository contains morphine hydrochloride gr. $\frac{1}{4}$, with ext. belladonnæ gr. $\frac{1}{8}$, enclosed in a closely fitting tinfoil sheath. The sedative and anodyne effects of this combination of drugs are thus rendered available, in a neat and convenient form, for use in affections of the tissues and organs adjacent to the lower bowel.

Royal College of Surgeons, Ireland.

Last week, in the Albert Hall of the Royal College of Surgeons in Ireland, the President of the College presented to the successful students the medals and prizes awarded at the termination of the previous sessions in the School of Surgery, and to Dr. Cuthbert Eccles, of Greystones, County Wicklow, the Royal Humane Society's testimonial for having on June 26th last gallantly rescued a gentleman from being drowned while bathing.

The President of the College, Mr. L. H. Ormsby, in the course of his inaugural address introductory to the Medical Session 1902-1903 in the schools attached to the college, referred to the present condition of the Royal Army Medical Corps and the Irish Poor-law Medical Service.

At the close of his address Dr. Cuthbert Eccles was called forward, and the President, addressing him said: Dr. Cuthbert Eccles, it is my proud privilege as President of this College to be the medium of presenting to you the Royal Humane Society's Testimonial for your heroism in plunging into the sea at Greystones, County Wicklow, on June 26th of this year, and gallantly rescuing from drowning Mr. W. H. Lumley. . Dr. Eccles, from that date you are an honoured Licentiate of this College, and as the dispensary medical officer of Delgany you have, coupled with the late Dr. Smyth, of Burtonport, and others, added further honour to your class and calling, for you have upheld the proud distinction of a brave man by saving a valuable life at the risk of your own. Your certificate has been signed by his Royal Highness the Prince of Wales as President of the Royal Humane Society, and I trust you may be long spared in health and happiness to enjoy your well-merited honour.

The President then presented the medals and prizes as follows:—

Winter Session, 1901-1902.—Stanley Memorial Gold Medal in Anatomy: J. J. Connolly. Descriptive Anatomy, Junior, W. St. L. Moorhead, 1st prize and medal; L. Lucas, 2nd prize and certificate. Senior, R. Bury, 1st prize and medal; I. Allaun, 2nd prize and certificate. Practical Anatomy, first year, J. B. Kelly, 1st prize and medal; J. Prendiville, 2nd prize and certificate. Second year, R. Bury, 1st prize and medal; R. A. Brown, 2nd prize and certificate. Third year, J. J. Connolly, A. N. Crawford and J. Parker (equal), 1st prize and medal. Practice of Medicine, M. Lochrin, 1st prize and medal; J. S. Sheill, 1st prize and certificate. Surgery, J. Spencer Sheill, 2nd prize and medal; W. R. Ormsby, 2nd prize and certificate. Midwifery, J. J. Connolly, 1st prize and medal; F. O'D. Fawcett, 2nd prize and certificate. Physiology, R. A. Brown, 1st prize and medal; E. Smith, 2nd prize and certificate. Chemistry, L. Lucas, 1st prize and medal; E. F. Ward, 2nd prize and certificate. Pathology, R. W. Burkitt, 1st prize and medal; W. R. Ormsby, 2nd prize and certificate. Physics, L. Lucas, 1st prize and medal; E. W. Greene, 2nd prize and certificate.

Summer Session, 1902.—Barker Anatomical Prize, £30, R. G. Allen. Carmichael Scholarship, £15, J. J. Connolly. Silver Medals in Operative Surgery, W. R. Ormsby and J. J. Ryan (equal). Practical Histology, W. W. Boyce, 1st prize and medal; A. C. Adams, 2nd prize and certificate. Practical Chemistry, C. M. Burton, 1st prize and medal; J. B. Kelly, 2nd prize and certificate. Public Health and Forensic Medicine, F. O'D. Fawcett, 1st prize and medal; L. F. Kelly, 2nd prize and certificate. Materia Medica, P. V. Dolan, 1st prize and medal; H. S. Misstear, 2nd prize and certificate. Practical Pharmacy, C. M. Burton, 1st prize and medal; E. J. Smallman, 2nd prize and certificate. Biology, C. M. Burton, 1st prize and medal; A. J. Faulkner, 2nd prize and certificate. After a vote of thanks to the President had been passed the meeting terminated.

Cork Medical and Surgical Society.

The annual dinner of the Cork Medical and Surgical Society was held on Saturday evening, November 1st, at the Imperial Hotel, Cork. Dr. P. T. O'Sullivan, President of the Society, occupied the chair, Dr. J. Cotter, Vice-President, occupying the vice-chair, and about fifty members and guests sat down to dinner. After the usual loyal toasts had been duly honoured, the President proposed the toast of the "Cork School of Medicine," which was responded to by Professor W. Ashley Cummins. The toast of the "Naval and Military Medical Services" was responded to by Colonel McNamara, R.A.M.C., P.M.O. Cork District, and Staff-Surgeon John Moore, R.N., while the toast of "Our Guests" was spoken to by Mr. S. H. Newsom, Hon. Treasurer of the Cork South Infirmary, and Mr. Hubert O'Keefe, L.D.S. Mr. M. D. Daly, J.P., Hon. Treasurer Cork Fever Hospital, then proposed the toast of the "Cork Medical and Surgical Society," which was responded to by the President. A number of songs and other musical items were rendered during the evening.

Deaths Under Chloroform.

An inquest was held at Nottingham last week on the body of a woman, age 32, who died under chloroform administered for the purpose of tooth extraction at the General Infirmary. The anæsthetic was given by the deputy-assistant house surgeon who said he had "great experience," but just after the teeth had been extracted the patient turned livid and the heart failed. No mention is made in the report of the method of administration or of the amount of chloroform used. The usual verdict was returned. A child, aged five months, died under chloroform at Guy's Hospital last week, while undergoing a second operation for strangulated hernia. The anæsthetic was given by the junior house physician. A verdict of death from misadventure was returned.

Suicide of a Medical Man.

An inquest was held last week by the coroner for Paddington on the body of Archibald James Bennett, age 28, who had committed suicide by taking hydrocyanic acid. The deceased was reading up for the fellowship of the Royal College of Surgeons, and nothing was elicited throwing light on his reason for taking his life. Incidentally a juryman raised the question whether suicide is to be accepted as conclusive evidence of insanity, the charitable view which coroners favour, and in the absence of any evidence as to the deceased's state of mind an open verdict was returned on that point. Fortunately the post mortem indignities formerly inflicted on persons adjudged *felo de se* have been abandoned, and four cross roads are no longer haunted as of yore.

National Orthopædic Hospital.

Mr. H. J. Tresidder having resigned the secretaryship of this hospital after more than nine years service, owing to his ill-health, Mr. Keith Anstruther has been appointed by the Committee of Management as Secretary.

Lady Health Visitor for Newport.

Miss Winifride K. Willey, of Newport, has been chosen female Health Visitor or Inspector for the borough of Newport out of twelve applicants who applied for the post.

Royal Navy Medical Service.

The session of special instruction at the Royal Naval Hospital, Haslar, terminated on October 24th. The prizes were awarded as follows:—The Gold Medal and Microscope to Surgeon Charles A. G. Phipps, late of the London Hospital; the Silver Medal and £10 worth of Books to Surgeon Stanley S. H. Shannon, late of Guy's Hospital. Surgeons in order of seniority:—

	Marks.		Marks.
Charles A. G. Phipps	4230	R. L. Jones, B.A. ...	2889
S. S. H. Shannon ...	3537	Robert H. Atkins, B.A., M.B.	2837
Charles K. Bushe, B.A., M.D.	3202	Charles J. O'Connell	2789
William R. Harrison	3141	James A. Thompson, B.A., M.B.	2756

THE CASE OF DR. RAINSBURY.

To the Editor of The Medical Press and Circular.

Sir,—Referring to the appeal made to assist Dr. Rainsbury in discharging the judgment debt and costs in the above matter, I beg to enclose a list of further contributions, and on behalf of Dr. Rainsbury and the Council of the Midland Medical Union to thank those who have so generously responded. I would add that there still remains a balance of £113 2s. 5d., towards which it is hoped that further donations will be made.

I am, Sir, yours truly,
George S. O'Rorke,
Sec. Mid. Med. Union.

The proprietors of 'Scott's Emulsion" have published, for distribution to medical practitioners, a very handy and compact "Diary and Emergency Note Book" for 1903. It presents special convenience in that the diary commences in Nov., 1902, and is continued to Feb., 1904—a novel and welcome variation from routine. In addition to various items of useful information there is an insurance coupon entitling the holder to £100 in the event of death, under certain specified circumstances.

NATIONAL ASSOCIATION FOR THE SUPPRESSION OF BAD LANGUAGE.

To the Editor of The Medical Press and Circular.

Sir,—The obscene and blasphemous language now so common—even, shame to say, on the lips of women and young children—is so shocking and so revolting that you will, I trust, lend us your kindly aid in inviting the co-operation of those who may be disposed to join us in our efforts to suppress the use of disgusting and profane words, and so wipe that foul blot from the character of our people.

I am, Sir, yours truly.
Greville Walpole, M.A., LL.D.,
Secretary.
1, Finsbury Circus, E.C., Nov. 5, 1902.

An Absent-minded Professor of one of the Welsh University Colleges was observed walking down the street with one foot on the kerb and the other in the gutter. "Good morning, Professor," said a friend; "how are you?" "Well," replied the Professor, "I thought I was all right, but for the last half-hour I have been limping in the most unaccountable manner."

Meetings of the Societies, &c.

LONDON.

Wednesday, November 12th.

South-West London Medical Society (Bolingbroke Hospital, Wandsworth Common).—8.45 p.m. Paper:—Dr. B. Fenwick: Backache in Women.

Dermatological Society of London (11, Chandos Street, Cavendish Square, W.).—5.15 p.m. Demonstration of Cases of Interest.

Hunterian Society (London Institution, Finsbury Circus, E.C.).—8.30 p.m. Paper:—Mr. A. H. Tubby: Recent Advances in the Treatment of Paralytic Deformities.

Thursday, November 13th.

British Gynæcological Society (20, Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. R. Snow, Dr. Macnaughton-Jones and others. Paper: Dr. Macnaughton-Jones: "The Propriety of Conservative Operative Procedures in Abdominal Cœliotomy for Adnexal Disease (illustrated by two specimens).

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).-4 p.m. Mr. Hutchinson: Clinique. (Surgical.)—Mr. Keetley: Coxa Vera.

Childhood Society (Library of the Sanitary Institute, Margaret Street, W.).—8 p.m. Mr. J. C. Hudson: Handicraft in Connection with Education.

Harveian Society of London (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Mr. A. Doran: Uterine Fibroids Considered from a Clinical and Surgical Standpoint. (Harveian Lecture.)

Friday, November 14th

Anatomical Society of Great Britain and Ireland (King's College, Strand, W.C.).—4 p.m. Annual General Meeting. Specimens by Dr. Salaman, Dr. A. Keith, and Dr. P. Thompson. Papers by Dr. R. J. Gladstone and Mr. F. G. Parsons.

Ophthalmological Society of the United Kingdom (11, Chandos Street, Cavendish Square, W.).—8 p.m. Cases and Specimens will be shown by Dr. A. Bronner, &c. 8.30 p.m. Papers:—Dr. F. W. Edridge-Green: On the Necessity for the Use of Colour-names in the Test for Colour-blindness.—Mr. S. Snell: (1) Avulsion of the Eyeball by Midwifery Forceps; (2) Paralysis of the Upper Movements of the Eyeballs; (3) Retinitis Pigmentosa in Five Generations.

Clinical Society of London (20, Hanover Square, W.).—8.30 p.m. Papers:—Dr. W. H. B. Brook: Cases illustrating the Clinical Features of an Epidemic occurring at Lincoln in May, 1902.—Mr. Mansell Moullin: Cases of Gastrotomy for Recent Gastric Ulcer.—Mr. H. McGavin: A Case of Strangulated Inguinal Hernia in which Reduction *en masse* was caused by the Employment of Taxis.

Tuesday, November 18th.

Westminster Hospital (Broad Sanctuary, S.W.).—4.30 p.m. Mr. Stonham: Surgical Cases (Post Graduate Clinical Demonstration).

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—Dr. Patrick Manson: Dysentery.

Appointments.

Bristowe, H. C., M.D.Lond., Medical Officer of Health for the Wrington District of the Union of Axbridge, Somerset.

Goodall, J. Strickland, M.B.Lond., &c., Lecturer on Biology in the Medical School, Middlesex Hospital.

Maguire, W. J., M.B., B.Ch., R.U.I., Surgeon to the North District of the Royal Irish Constabulary in Belfast, *vice* D. McDonnell, M.D., R.U.I.

Miller, E. J., L.S.A Lond., House Surgeon to the Tynemouth Victoria Jubilee Infirmary, North Shields.

Mole, Harold F. F.R.C.S.Eng., Honorary Assistant Surgeon to the Bristol Royal Infirmary

Rubra, H. H., M.D.Brux., M.R.C.S., L.R.C.P.Lond., Anæsthetist to the Great Northern Central Hospital.

Scharlieb, Mary Ann Dacomb, M.D., M.S Lond., Physician for Diseases of Women, Royal Free Hospital, Gray's Inn Road.

Vaughan, Ethel May, M.D., B.S.Lond., Assistant Physician for Diseases of Women, Royal Free Hospital, Gray's Inn Road.

Vacancies.

Borough Asylum, Portsmouth.—Assistant Medical Officer. Salary £120 per annum, with board, lodging, &c. Applications to the Medical Superintendent.

Borough of Colchester.—Urban District.—Appointment of Medical Officer of Health Salary £475 per annum. Applications to H. C. Wanklyn, Town Clerk, Town Hall.

Bradford Royal Infirmary.—Dispensary Surgeon. Salary £100 per annum, with board and residence Applications to William Maw, Secretary, Royal Infirmary, Bradford.

Cahirciveen Union, Glanbehy Dispensary District.—Temporary Medical Officer. Remuneration £5 5s. per week. Immediate application to Thos. C. FitzGerald, Clerk of Union. (See advt.)

City of Nottingham Workhouse Infirmary.—Senior Resident Medical Officer, salary £160 per annum, and for the post of Junior Resident at a salary of £120 Apartments, board, washing, and attendance provided in each case. Applications to G. Muncaster Howard, Clerk to the Guardians.

Middlesbrough County Borough Asylum, Marton-in-Cleveland, Yorkshire.—Assistant Medical Officer. Salary £130 per annum, with furnished apartments, board, and washing. Applications to the Medical Superintendent, as above.

Penryn, Corwall.—Ancient Order of Foresters and Independent Order of Rechabites.—Surgeon. Immediate application to R. F. Stephens, Penryn, Cornwall. (See advt.)

Warrington Infirmary and Dispensary.—Resident Surgeon. Salary £100 per annum, with furnished residence and board. Applications to J. H. J. Hampson, Secretary.

Worcester County and City Asylum, Powick, near Worcester.—Assistant Medical Officer. Salary £140 per annum. Applications to Medical Superintendent.

Births.

Basden.—On Oct. 28th, at Stanford-le-Hope, Essex, the wife of H. S. Basden M.R.C.S., L.R.C.P Lond., of a daughter.

Berry.—On Oct. 27th, at Wansford House, Watford, the wife of F. Haycraft Berry, M.D.Lond., of a son.

Dobie.—On Nov. 3rd, at 11, St. John Street, Chester, the wife of Herbert Dobie, M.D., of a daughter.

Morgan.—On Nov. 4th, at Marteg House, Westcliff-on-Sea, Essex, the wife of W. Harmon Morgan, M.R.C.S., L.R.C.P. Lond., of a daughter.

Stanford.—On Nov. 4th, at Sutton Valence, the wife of W. Bedell Stanford M.R.C.S., &c., of a daughter.

Ward.—On Nov. 6th, at 40, Berners Street, Ipswich, the wife of F. Fowler Ward, M.B., B.C., of a son.

Marriages.

Elliott—Wright.—On Nov. 4th, at St. Bartholomew's, Sydenham, S.E., Staff Surgeon Horace Elliott, R.N., son of Samuel Elliott, B.A., barrister, of Benfleet, to Mary Elizabeth, second daughter of the late George Cross Wright, of Challow House Berks.

Hartley—Stewart.—On Nov. 6th, at St. John's Church, Edinburgh, Arthur Conning Hartley, M.D., F.R.C.S.E., Bedford, to Margaret, eldest daughter of the late James R. Stewart Esq., M.A.Oxon.

Deaths.

Goullet.—On Oct. 30th, at 7, Cliff Terrace, Budleigh Salterton, Devon, Arthur Peter Goullet, M.R.C.S.Eng., L.R.C.P.Lond., late of 2, Finchley Road, St. John's Wood, London, second and only surviving son of the late Commander Charles Goullet, R.N., aged 74.

Ward.—On Oct. 27th, at St. Bartholomew's Hospital, Herbert S. Ward, M.B., B.S.Lond., M.R.C.S., L.R.C.P., of Rhiwbina, Glam., aged 25.

THE CONFLICT OF MEDICAL TESTIMONY IN COURTS OF LAW. (a)

By L. H. ORMSBY, M.D., F.R.C.S.,

President of the Royal College of Surgeons, Ireland; one of the Senior Surgeons of the Meath Hospital and co. Dublin Infirmary.

The conflict of medical testimony in courts of law has been for many years a matter of great moment to us all. Therefore, I need not apologise for making it the subject of my present address.

I have frequently observed in the Dublin law courts the most distinguished physicians and surgeons divided in their opinions as regards the cause, present condition, and probable future result of real and imaginary injuries or diseases. In face of the conflict of medical evidence it is no wonder that judge and jury sometimes find it almost impossible to arrive at the justice of the case. Let me give you a typical example—railway shock. Where a person complains of injury in a railway collision, a surgeon is called on, either by the alleged injured person or by the railway company, to express his opinion. He must consider the case from at least four aspects:—

1. As to whether the person complaining has really been injured at all.
2. If injured, what is the nature and extent of the injury?
3. Whether the injury is permanent, or likely to be permanent?
4. If not permanent, when will restoration be ensured?

As regards the first point the great difficulty depends upon what position the surgeon holds to the alleged injured person, whether he is the usual medical attendant, or whether he is engaged in the interest of the railway or other defendant company.

If he is the usual medical attendant of the patient his task is less difficult. The patient will inform him without reserve concerning everything connected with the alleged injuries, and from previous knowledge of his constitution the surgeon will have ample opportunity of comparing accurately the patient's present condition with his state previous to the accident, and from his personal intimacy with the patient he will be in a position to estimate any overstatement of his sufferings.

On the other hand, where the surgeon is the recognised medical adviser of the railway company, or he may happen to be called in for the occasion to protect their interests, his tasks and duties are not nearly so simple. In accordance with professional etiquette he cannot visit the patient unless in the presence of or in consultation with the patient's medical attendant.

This usage is, of course, right in the main, but it has disadvantages. It often leads to inconvenience and loss of time in order to arrange an appointment that will suit all parties concerned. Secondly, when the patient has been made aware of the projected visit he prepares himself for the ordeal in great excitement, describing his sufferings in such a striking and vivid manner and with such minute detail as to compel the medical examiner to use all the knowledge and sagacity he possesses to distinguish whether what has been detailed to him is real, feigned, or exaggerated. Hence it has occurred to me, and doubtless to others of my brethren also, that the cause of truth and justice would be better served, in some instances at least, by leaving it to the surgeon to exercise his own discretion in visiting without notice certain patients alleged to be suffering from injury. Then, and only then, will he see the patient in his natural or real state. Such visits I feel certain would help greatly to distinguish the cases of feigned from those of actual injury. In support of this view I can cite eminent authority.

Mr. Erichsen, referring to the conduct of railway surgeons when visiting a patient on the part of the defendant company, suggestively observes "The patient is not yours—he probably does not wish to consult or even see you. Perhaps you are admitted to an interview with him and to an examination of him only after consultation with his solicitors and by their consent, or in virtue of the judge's order. He most probably looks upon you as being hostile to him and as coming with a view to making light of his misfortunes. Hence you will usually have but few opportunities allowed you of seeing the patient, generally only once, at most, twice or thrice. He is always prepared beforehand for your visit, he is excited, annoyed, or apprehensive with respect to it. You do not consequently see him in his usual frame of mind, and the mental disturbance thus occasioned may react injuriously upon and greatly aggravate his physical ailments. Above all you have no opportunity of taking him unawares and unprepared when your visit is expected, because, if unexpected, you would have a good opportunity of judging whether this symptom or the other really existed, or if it existed to the alleged extent."

Speaking from personal experience, I have occasionally gone with the medical attendant of the patient without previous notice of my intended visit having been given and the information gained under such circumstances has been at times remarkable. In one instance, when we entered the room the patient was sitting on a chair. He received us pleasantly in a laughing, joking manner, not having the least suspicion that I was the railway company's doctor. The moment he was informed who I was and the nature of my visit the whole aspect of his face suddenly changed. Instead of a pleasant, open countenance, he assumed a sullen, dark, dejected look, and seemed greatly annoyed that he had been taken unawares. In another instance where my visit was expected, before my examination was over I was convinced I had to deal with a case enormously exaggerated, for the injury the man had received was so slight as to be incompatible with the symptoms described by the patient himself. The patient was so determined to aggravate and exaggerate his symptoms that for many months he prepared himself —by a continued invalid régime, and nursing his injuries mental and physical so that his imaginary ailments, grew into stern realities—so that he became a confirmed wreck, all for the few hundred pounds he received as compensation. This man managed his case so well that he deceived his own medical attendants to such a degree that they were indignant when I ventured to suggest that some of the symptoms complained of were exaggerated. On another occasion I paid a visit on behalf of an Accident Assurance Company to a gentleman who it was alleged had received very serious injuries by falling off his bicycle in a collision with a car. It was alleged that this gentleman was in bed. On arriving at his house and asking who was his medical attendant. I found he had no medical man attending him. that he was not at home, but was that day out shooting on the Dublin mountains.

(a) Presidential Address read at the Opening Meeting of the Surgical Section of the Royal Academy of Medicine in Ireland, Nov. 14th, 1902.

Of course, I am not suggesting that severe and permanent injuries do not take place as well as other accidents. I have on many occasions attended patients who have been severly injured. But I do say that one of the greatest difficulties in a medical man's investigation is to distinguish between real and feigned injuries. Hence the regretable conflict of medical testimony in the law courts. I have heard advocate's comment upon it as derogatory to the members of a noble profession and as calculated to defeat justice. An honest difference of opinion is quite another matter, but it is the direct conflict of evidence as to the presence or absence of serious symptoms in obscure cases, like railway shock or railway spine that lead the public to conclude that doctors will expand or contract their powers of observation as to diagnosis and prognosis according to the interests of the side for which they are paid.

In this city, when an important case of personal injury is to be tried in the law courts, the solicitors retain the services of a powerful Bar, usually three K.C.s and a junior on each side. Next to securing the Bar the question of medical witnesses crops up. Counsel directs the solicitor to have a consultation with the medical attendant, with the result that the doctor recounts what he knows. Senior counsel may think his evidence is weak and will not influence a jury or that he is not sufficiently known. Accordingly some leading surgeon is frequently retained to back up the medical attendant's opinion. This gentleman is approached by the solicitor. The fee is arranged, and his attendance is secured to give evidence for the plaintiff. The moment the defendant company learns that an eminent medical witness has been retained their solicitor is put in motion to secure an equally eminent medical expert to give evidence on their behalf. Then it is sometimes thought desirable to have another medical man on behalf of the plaintiff. This is no sooner known than the defendant company in like manner engages the service of yet another doctor. Thus the case comes on for trial. The leading medical witnesses are heard on each side, Hard swearing takes place, resulting in conflict of testimony. How does this affect the court? Lord Coleridge says, "Such conflicts of scientific opinion are puzzling to a judge who knows little, and to a jury who probably knows less, of science."

His lordship, it may be observed, omitted all reference to the knowlege of medical science possessed by the Bar, but it probably would be only fair to assume that it does not occupy a higher standard than that at which the learned judge so modestly places the acquirements of the Bench.

Conflict of medical opinion in courts of law I know gives persons who are inclined to speak slightingly of the profession an opportunity to misrepresent the real point at issue, as regards the difference of opinion, which frequently is more apparent than real. Indeed, I feel certain that it occurs much less frequently than is represented. Mr. Erichsen thinks that in at least 90 per cent. of all cases of surgical injury in which claims for compensation are made there is perfect accord between the medical men concerned as to the nature, the extent, and the possible duration of the injury. Such cases as these are necessarily settled out of court, and as they do not become the subject of judicial investigation they do not attract the attention of the public in the newspapers. In the small remainder of the cases, not amounting to one-tenth of the whole, a discrepancy or conflict of opinion takes place which is not as a rule with respect to the facts of the case, but has reference to the possible pathology, the ultimate extent of the injury, and the probable duration of the symptoms. When we consider that these injuries are chiefly lesions of the brain and spinal cord, affecting organs and structures the pathology of which is not as yet accurately determined, and consequently is less understood than that of any other part of the body, we cannot feel surprised that there is an occasional want of unanimity even among men who are exceptionally well-informed on the subject of the injuries and diseases of the nervous system.

In every department of life conflict of opinion occurs. In politics, religion, engineering, chemical and biological science, and in the law itself to at least as great an extent relatively as that which is met with in medicine and surgery. Let us see, then, to what extent conflict of opinion occurs in the law courts among the members of our own profession.

There are three classes of medical witnesses who appear in the small proportion of compensation cases which in the end drift into courts of law.

First, there is the *bona-fide* medical attendant of the case. Secondly, there is the recognised medical officer of the railway or other company. And, thirdly, there is the consulting surgeon or medical expert called in from his acknowledged acquaintance with the subject of the injury alleged to have resulted in the case at issue. The first two witnesses detail the actual facts, the present condition, and the various symptoms and signs observed by them or ascertained after careful examination, and the weighing of the objective and subjective symptoms present. As a rule there is not much difference of opinion between these witnesses. The conflict of testimony generally appears among the "experts" called on either side to testify as to whether the injury complained of is feigned or real, and if real, the probable duration of the lesion and the future effect it may have on the patient. I have already stated how these experts have been brought into the case, namely, that their services have been secured by the litigants themselves to give evidence. I think medical experts ought to be nominated by the Court, and paid under the directions of the Court.

I agree with Mr. Erichsen when he says "The method of appointing experts is radically wrong and is productive of many evils." A medical man who is retained and paid by a litigant, being only human, does not see why he should not earn twenty or thirty guineas for his opinion when opportunity occurs. With the purest intentions possible, unconsciously, almost instinctively, he is apt to become biassed in favour of the side he is called upon to support. He is inclined to look for the strong points on his own side and the weak ones on that of his opponents. It is fatal when a medical witness becomes an advocate. He should be in a position to guide the court in the direction of what he believes to be the truth. Conflict of opinion among surgeons as regards actual facts rarely or ever occurs in cases of pure surgical injury, such as fractures, dislocations, ordinary wounds, but it is as to the deductions from admitted facts, and the opinions that may be legitimately based thereon, that different views are expressed. The difference of opinion thus conveyed appears to a non-medical tribunal to be much wider than it really is. It is often, as has been said by Mr. Erichsen, rather a difference of degree than an actual divergence of opinion as to actual conditions, and if the case were tried before a tribunal possessing the requisite amount of medical knowledge to form an independent judgment, these differences would be narrowed to a very slender line, if not reconciled. Sometimes discrepancies in scientific opinion cannot be explained away, or due value assigned to conflicting statements, in consequence of the want of scientific knowledge on the part of the tribunal before which the case is tried.

How is it possible, to quote Lord Coleridge again, for a judge who knows little of science, and a jury who knows less, to form a trustworthy estimate of the scientific medical evidence that is brought before them? This is especially the case when that evidence relates not to matters of fact but to matters of opinion on some of the most unsettled problems in physiology and pathology, namely, those connected with the functions of the brain and spinal cord.

What would be said if a leading physician or surgeon, having little or any real knowledge of law, were asked to try a case involving some of the most intricate, obscure, and complicated questions in the law of real property? Suppose before him several King's Counsellors, debating those questions from opposite standpoints. Would it be possible for him to come to anything like a trustworthy conclusion, or one that would be satisfactory to the members of the Bar? In the ordinary arbitrations for the compensation to be paid for lands compulsorily taken questions of law arise, and the arbitrator is entitled to have a legal assessor to guide him.

Surely the cases are parallel; on the one hand, the judge who knows little of science in a case which teems with scientific and technical possibilities of the most obscure character; on the other hand a surgeon who knows less of law dealing with a legal problem.

Therefore it is that I respectfully suggest that the court in actions for personal injury should be assisted by a medical assessor of undoubted knowledge and eminence who would assist the judge, enabling him to weigh and estimate the true value of the expert evidence given *pro* and *con*. If in the Admiralty Court it has been found desirable for the presiding judge to call to his assistance two nautical assessors who have practical knowledge and experience in navigation where there is a question of responsibility for a collision, how much more should it be necessary for a judge in cases of railway shock to call to his assistance medical assessors selected and paid under the direction of the court who are above and independent of the contending sides, and who could weigh all matters of medical evidence at their true value? So strongly did the Council of the Royal College of Surgeons in Ireland think on this matter that last year several discussions took place. On March 7th, 1901, notice of motion was given in these terms:—

"That the Council of the Royal College of Surgeons in Ireland is of opinion that the conflict of medical testimony so often apparent in the law courts is derogatory to the profession and is frequently subversive of justice. The Council therefore consider it desirable on public grounds that provisions somewhat similar to those already in force under the Workmen's Compensation Act, 1897, should be made for the appointment of independent medical referees in all cases in which there is likely to be a conflict of medical testimony where suitors seek compensation for personal injury."

A sub-committee of the Council was appointed to consider the matter, and their report came up for discussion at the Council meeting April 2nd, 1901. They recommended the adoption of the following resolution;—'In cases of actions for damages for personal injury, the Council of the Royal College of Surgeons in Ireland is of opinion that the court should obtain an independent surgical opinion, having regard to the necessary technical nature of surgical evidence, especially in cases of alleged injury to the spine."

After considerable discussion, the Council unanimously adopted a resolution in the following terms:—

Resolved,—"That the President and Council of the Royal College of Surgeons in Ireland having regard to the necessarily technical nature of medical evidence, are of opinion that in cases of actions for damages for personal injuries, the court should obtain the assistance of a medical expert other than those employed by the parties in the suit."

This resolution was printed and a copy sent to each of the judges of the Supreme Court of Judicature in Ireland. But, so far as I am aware, the judges have never replied to this communication.

The action of the Council is not generally known. Perhaps this is the first *quasi*-public intimation. The administration of justice is at all times a subject of public concern. Hence I respectfully venture to hope that the suggestion of the Council of the Royal College of Surgeons, a suggestion which tends to the dignity of the medical profession and to the promotion of the ends of justice, will be duly considered by his Majesty's judges in Ireland and England at an early date.

GASTRIC ULCER. (a)

By F. J. SMITH, M.D., F.R.C.P.,

Physician to the London Hospital.

Everyone is familiar, both by reading and possibly by actual experience, with the two common forms of definite ulceration of the stomach, *e.g.*, the small punched-out so-called peptic or acute, and the large indurated or chronic, but I do not think we have been so alive to what I believe to be a third form. My own experience of this third form has led me to attach very great importance to it. The first case that attracted my attention occurred some ten years ago; it was that of a man about forty-five or fifty years of age, who came to me at the City Road Chest Hospital with all the symptoms and physical signs of pulmonary phthisis. I gave him medicine, and told him to see me again in a fortnight. About five or six days later his friends came to see me and said that he had suddenly passed a large quantity of blood per rectum and died. I asked for and obtained a necropsy. The phthisis was there right enough, of an ordinary type, but the intestines from stomach to anus were full of blood, the exact source of which was at first quite inexplicable, as I could discover no gross lesion in the stomach (its obvious *primary* source); closer scrutiny of the viscus, however, showed me at the cardiac end a hole, about the size of a ordinary pin's head, leading directly into a small vessel; beyond the hole or round it there was no trace of any ulceration visible to the naked eye. At the time I thought I had possibly a peculiarly-situated single focus of tubercle to deal with, and allowed myself to say that I had seen a case of tuberculous ulcer of the stomach. I removed the piece of the organ with the hole in it, and intended to have sections cut; but unfortunately the specimens got lost, and so the case remained really unexplained till further evidence accumulated of what I now believe to be its real nature.

(a) Abstract of an Address delivered before the East Surrey Branch of the British Medical Association at Reigate, October 9th, 1902.

During the last three or four years in the post-mortem room I have found in at least two or three persons, in whom there was no suspicion of tubercle at all, a precisely similar condition. The history of the last one, by the kind courtesy of Mr. Rigby, I am enabled to give. The body was that of a girl, æt. 22, a barmaid. Her previous history is unattainable; but so far as the notes go they are not incompatible with the supposition —they do not specifically state that it was so—that she was one of that very common type of anæmic girls who suffer from indigestion and pain after food; at any rate she was admitted, looking very blanched, as a case of gastric ulcer with hæmatemesis, and transferred at once to Mr. Rigby for operation. The history of her present acute illness was as follows:—She had had a bilious attack on Thursday, vomited a pint of blood on Friday, is said to have had several fainting attacks on Saturday and Sunday, and on Tuesday vomited another half-pint of blood, so that there was a reasonable suspicion that she would bleed to death if something radical were not done to check the hæmorrhage. Mr. Rigby operated. The notes run—"No ulcer was found, but a villous looking patch about the size of a shilling was found, from which the blood seemed to be coming; this patch was sequestrated by a purse-string suture, &c." (From my immediate point of view the surgical procedure is of no particular interest.) At first she did well, but suppurative parotitis supervened with œdema of the glottis, necessitating tracheotomy. She struggled gamely with these difficulties, but on September 24th she vomited blood again, and died on the 25th. At the post-mortem I found the surgical situation perfect so far as the stomach was concerned (except that the sutures were unabsorbed and, indeed, unaltered—a point for surgeons to note). The wounds were healed perfectly, and the old affected region effectually sequestrated; but near the pylorus, some inches from the old spot, was a small pin's-head-sized hole leading directly into an open vessel, with no trace to the naked eye of any ulceration or swelling, or other pathological condition than a simple solution of continuity in the mucous membrane. The histories of the other cases differ a little from this one, but the post-mortem appearances were identical in all. Such is my definite evidence of facts from the dead-house, but in the living the evidence is nearly as strong

For the last four or five years Mr. Moullin has operated for me upon several cases of gastric ulcer, the operation being demanded for various reasons which we may discuss later—perforation, suppuration, hæmorrhage, life a burden, &c.; but among those upon whom he has operated for hæmorrhage it is very noteworthy—and I believe his experience coincides with that of all my surgical colleagues—how frequently he has to report, "I found no ulcer, but only a small hæmorrhagic or petechial-looking spot."

I am, therefore, on this evidence forced to the conclusion that this erosive form of ulcer is of much more frequent occurrence and of much more clinical importance than has been generally admitted, for I believe that it is the condition which is primarily at the bottom of all cases in their early stages; that, in other words, it is the starting-point of most, if not all, ulcers of the stomach of any form whatever.

It must be in the experience of all to have met with cases in which all we have been able to say at first is, that dyspepsia is present, and the dyspepsia has later on been followed by severe hæmatemesis, and possibly by all the classical signs and symptoms of ulcer. Can we, in the light of my present text, avoid such incidents? I fear I am obliged by practical evidence to say that in ordinary life such incidents or accidents will, and must, remain inevitable in a certain proportion of cases, for it is impossible to send every patient to bed for even two or three days who comes complaining of indigestion, and yet that is what the position comes to mean if we would act with absolute safety; for I am quite convinced that patients with these erosions do not complain at first of anything but the mildest symptoms of indigestion. Time after time I find, on looking up my old notes of cases of hæmatemesis that, even on the most careful inquiry, a little wind or fulness after food, a good preliminary appetite too easily satisfied, slight pain sometimes at once, sometimes delayed for an hour or so after food, are all that has ever been noticed. Such patients are not fit to be very thoroughly tested in regard to localised pain on pressure; but when I make the statement "that when erosions only are present there is no localised tenderness on pressure, only a generalised tenderness of the whole epigastrium, that when a definite gross ulcer has been present there has been this localised tenderness," I am not stepping outside any actual observations noted down, though I am quite willing to admit that it is based more on negatives than on exact positives; a risky position I admit, but one which can lead to no harm, and may help to the avoidance of accidents in some few cases. The position I take up is this, when we see a patient between, say fifteen and forty, complaining of indigestion without any definite exciting cause, we can neither affirm - without hæmorrhage—nor deny the possibility of erosions being present; and if we remember the possibility, we shall be inclined, whenever it is at all practicable, to send the patient to bed for a few days, and either starve him (or her more frequently) completely, or feed on pulp and slops. If hæmorrhage has occurred in a case with short duration of symptoms, I go so far as to say that erosion is the most likely condition present. We must, however, take the elements of diagnosis and consider the various groupings of them, for it is in the association and linking together of the symptoms, the symptoms complex, rather than on the individual items, that diagnosis mainly rests. The items themselves are: 1, Age; 2, sex; 3, pain or discomfort; 4, hæmorrhage; 5, perforation; 6, duration (*a*) over a length of time, (*b*) in an attack; 7, severity of symptoms complex; 8, local tenderness; 9, vomiting, and the nature of the vomited matter.

It would occupy too much time to follow out every possible combination of these, but I think we may usefully consider some of the various diseases known to occur in the abdomen which require to be distinguished if we would treat our patients on any rational basis.

It may seem rather far-fetched to suggest that a movable kidney may simulate gastric ulcer, but on at least three separate occasions I have had some difficulty in determining how much of the pain after food, and the nausea in youngish women, was due to movable kidney, which was undoubtedly present, and how much to a pathological condition of the stomach.

Acute gastritis practically never occurs (under circumstances that necessitate differentiation from ulcer) in young subjects without a fairly obvious cause in the shape of too much "lobster salad" or something obviously irritating to the stomach. It is sudden in its onset, and associated with much nausea and retching; points in which I am led to believe it differs from gross gastric ulcer, though possibly resembling multiple erosions. The appetite is in abeyance from utter distaste for food, whereas in gastric ulcer the appetite may be good.

A bilious attack I cannot define as I am rarely in a position to see one, but in adults my impression is that it is the same thing as acute gastritis, and the "bilious" part of the name has arisen from the sole fact that the vomit becomes almost pure bile, owing to *anti*-peristalsis reaching the duodenum. In young persons I believe a condition does exist which has the same phenomena during its presence as those of acute gastritis in adults, but it is brought on by very slight causes indeed, generally of a reflex—not direct gastric—origin, a sort of neurosis allied in its primordial nature to epilepsy, the distinguishing feature being the history of a "delicate stomach" quite from early childhood or even infancy. The severity of the attacks begins to diminish at the age of, say, fifteen to twenty, when ulcers begin to intrude into the diagnostic horizon. Accepting, as I think we must, the existence of such a disease as acid dyspepsia, the following constitute its symptoms complex. The patient is an adult, say from thirty to fifty; pain rarely or never comes on till two or three hours after food; it is much, and that almost at once, relieved by vomiting, and it is also relieved very rapidly by the ingestion of some food or plain liquid diluent. It requires to be separated from chronic gastric ulcer, which I think can usually be done by the *combination* of the presence of intense general pain and the absence of a lump to be felt, or local tenderness to be elicited. If a chronic ulcer should complicate it, then dilatation is likely to be a marked feature.

Prognosis is always so bound up with treatment that it can hardly be discussed apart from it. To prevent confusion and repetition in the discussion of the treatment of gastric ulcer, we must take it in separate divisions.

The first group I make from this point of view is a very large one, viz., those cases in which dyspepsia is the prominent feature, but in which there are no certain indications, such as hæmorrhage, to give a strong lead. Taking the young anæmic girls first, I have never yet found a case which was not improved by iron given at once, provided the tongue was not badly furred. It is generally stated that the stomach should be cleaned up by bismuth, &c., before iron is given; but I cannot say that this accords with my experience, with the sole proviso regarding the tongue mentioned above. I do not think this group, whether anæmic or not, offers any new or special features in treatment for me to advance; but the rapid subsidence of all trouble directly the patient goes to, and remains in, bed is little short of miraculous, and it is this fact which makes me say that, whenever it is in the least degree possible, young patients with indigestion without a very definite exciting cause, or even with one, should be put to bed. The next question is, When should we let such a patient get up? I believe that the stomach will heal from erosions as rapidly as a throat will heal from congestion, and that in three or four days it is probable that danger is past, but if any doubt still lingers in your mind, there is a very simple plan that I learned from the practice of Dr. Samuel Fenwick, viz., to get the patient to swallow a little salt solution (ʒj. of salt, ad. ℥ij of water) in the morning on an empty stomach; if there is still any raw place this will cause a good deal of temporary pain, and will also serve to show whether the condition has passed on to actual gross ulceration or not, and whether, if it has, the ulcer has healed. The pulpy diet, with which you are all as familiar as I am, I pass over with only one remark, but that one I wish to make as emphatic as possible: raw milk should not be given alone; junket, broken-up custard, soft bread and milk, &c., may be given in small quantities at a time, but the patient must not be allowed to drink ordinary raw milk, owing to the large, hard (for the stomach) curds that are produced.

The second group is a very different one to discuss from the point of view of treatment, and I may at once say that I do not think we have yet sufficient experience to dogmatise on it. The group itself is that one in which we feel sure that an acute ulcer is present, and it has three separate types:—(*a*) Ulcer diagnosed by local tenderness, &c.; (*b*) Ulcer diagnosed by hæmorrhage; (*c*) ulcer diagnosed by perforation.

Type (*a*) must be put to bed and treated, so far as general management is concerned, absolutely on the lines of the first group. One principle here, however, I might emphasise, as I have come to regard it as a vital one, and that is if vomiting is a prominent feature, we must give the stomach absolute rest—water and medicine are the only possible exceptions—and starve the patient even for four or five days; in acute cases nutrient enemata may be administered, but I think they do very little good. Food excites retching, which is bad for the patient and for the ulcer. When, after starvation, food is resumed, dry food is the best - a dry crust or a biscuit, which cannot be swallowed till thoroughly masticated. The main thing is to throw to the winds any idea of regular meals or feeding; but let the patients nibble a biscuit or crust, restricting them very rigidly in quantity. As regards drugs, nitrate of silver has given me as good results as anything else, but doubtless bismuth is very valuable. If the patients do not get well in fourteen to twenty-one days, they are very liable to drift into my third group.

Type (*b*).—It is really on the treatment of hæmorrhage from the stomach that opinions will probably differ most. No one, I suppose, would suggest any active surgical procedures in a first attack of hæmatemesis—it is astounding what a large amount of blood may be lost, and yet the patients almost invariably do well; but when the hæmorrhage is repeated a second, third, or fourth time, and death seems to be almost inevitable if the bleeding vessel be not secured, it is then that the surgeon must step in. On percentage results of these cases compared with the non-operated ones the question must ultimately be decided. I doubt if it is possible to lay down any hard and fast rule, so much depends on the condition of the patient at the time; but if I am to formulate a rule, it would run something like the following:—"If a patient has had three serious hæmorrhages within, say, five days to a week, and during that time the pulse has very markedly increased in frequency, we ought to advise surgical measures."

The direct medical treatment consists in bed and absolute rest of mind and body, for which purpose I am sure opium is the best drug; it must be pushed freely, say five or six minims every hour, till the patient is well under its influence, and then in doses sufficient to keep him so. Nothing in the shape of food must be given; but water or ice, at the request of the patient, may be given in small quantities. I think any of the direct astringent and constringent drugs may be useful, but I doubt the wisdom of ergot unless given in very large doses. Extract of suprarenal seems to give good results in some severe cases, as it would appear to have a marked local as well as distant action.

The third group includes cases in which there is a history of at least a year's duration of what the patient calls severe indigestion, including possibly, hæmatemesis, severe pain in the abdomen, and probably some vomiting It is very important in this group to make up one's mind whether one has to deal with a gross organic lesion of the stomach or with functional trouble only (acid dyspepsia, &c.); but for my present purpose we must assume that the former is the case. What, then, are we to do? The first thing is to ascertain what treatment has already been employed, because the cases may be divided into those that have drifted while under treatment and those that have drifted without seeking professional advice. If, on inquiry, we find that the patient has not been to bed and remained there for at least two weeks, he must be sent there and treated carefully in the same way as in the first group. Further procedures will depend on—(1) The results obtained from such method of treatment. (2) What is found: (*a*) a contracted stomach; (*b*) a dilated one; (*c*) a lump. (3) The inclinations of the patient derived from the amount of local crippling. (4) Accidents—hæmorrhage, perforation, vomiting.

If hæmorrhage occurs in this chronic form of ulcer, I think operation is as distinctly called for as it is when perforation has taken place.

If we find a contracted or dilated stomach, it seems to me equally imperative to offer the patient the relief which operation will bring, and which, in the nature of things, cannot be permanently afforded by medical measures. Lavage may relieve for a time, but not for long. If we cannot find any gross evidence of permanent mischief, and have to trust to the complaints of the patient for our diagnosis, it is then our duty to try and relieve these symptoms by medical means first. Lavage is the most important procedure for doing this, as it will frequently give relief for a long time. Of drugs I have obtained the most marked relief from bicarbonate of soda, forty grains in a wineglassful of water, about four hours after a meal. Listerine (a drachm in a tumbler of water on an empty stomach) I have known also help very materially. But it is not much use pouring drugs into a foul stomach filled with fermenting food. If, however, a chronic ulcer be present, *i.e.*, if the case be not one of acid dyspepsia, I believe that any and all medical measures will eventually prove ineffectual, and ultimately the patient must choose between an operation and a condition of constant misery and pain. It is this that renders accurate diagnosis so important.

THE PROPRIETY OF CONSERVATIVE OPERATIONS IN CERTAIN CASES OF ADNEXAL DISEASE DEMANDING ABDOMINAL CŒLIOTOMY.

ILLUSTRATED BY SPECIMENS. (*a*)

By H. MACNAUGHTON JONES, M.D., F.R.C.S.I. and Ed.

The question as to whether we have not exhausted the lessons which the exhibition of pathological specimens illustrative of the diseases of the pelvic organs of women can possibly teach, sometimes forces itself upon us. Has not every conceivable morbid process or change been illustrated and discussed until further inspection of the same states is only a waste of time and a vain repetition of teachings and arguments which are intended rather for our personal glorification and advertisement than for the only excusable object in advancing them—namely, the progress and advantage of the art or science under the ægis of which a society exists? I fear most of us must plead guilty to the soft impeachment.

Let me say a word or two on this subject before entering upon the discussion of a point of practical moment in gynæcology, which the two specimens I show illustrate. The present state of gynæcological knowledge, both in its theoretical and practical aspects, is anything but complete. True, some parts of the art are apparently crystallised, and the final type has seemingly been arrived at, but others are yet in the transitional and modifying stages, and many more are in the cruder colloidal condition. Many examples of this fact will occur to you, and it is not necessary for me to do more than briefly refer to a few of them. The statement applies equally to the etiology, the pathology, the therapeutics, the clinical handling of, the operative measures applicable to, and the correlative morbid conditions and associated organic changes of, such conditions. Instance the etiology of fibromata of the genitalia, the pathology of various mixed benign and malignant processes, the therapeutics of disorders of menstruation and vulvar and vaginal diseases, the clinical aspects of different forms of endometritis, the operative measures to be followed in certain cases of cancer of the uterus, pelvic suppurations, and displacements of the uterus, while there also remains a vast field for investigation in the study of the *associated* diseases which precede, accompany, or follow, affections of the female genitalia. This latter study does not merely include such questions as the clinical and pathological relation of appendical to ovarian inflammations, the spread of tuberculosis, the contrast of the spread of sarcoma with that of cancer, the influence of disease in the adnexa of one side on the health of the other, but it also embraces the legion of reflex clinical symptoms, if not pathological changes, which are associated with diseases of the genitalia, whether in the great viscera, or in the nervous system. These are some few examples of the truth of my assertion that the resources of gynæcological investigation are far from being exhausted.

This being so, I think you will agree with me that the elucidation of such problems is more surely affected by the careful examination of the morbid parts removed by the operator himself, who can throw the most certain light on the natural position, appearances, anatomical connection, and the difficulty of removal of such growths or affected organs. On the other hand, I think the casual examination and haphazard expression of opinion on diseased structures, mutilated in the removal, altogether altered by their mode of preservation, and without any accurate clinical record of the previous history, generally does more harm than good, is retrogressive rather than progressive in its effects, and in a society tends rather to demoralise its scientific atmosphere than to impart an invigorating influence to those who take part in its debates. I say this here because, when asking Fellows of our own Society to bring specimens of interest, I have frequently met with the reply, "Oh yes, I could bring specimens, but what is the use? The exhibition of specimens is played out." On the contrary, I maintain that there is hardly an operation *justifiably* performed in which a morbid growth, organ, or structure is removed, which does not afford some useful clinical or therapeutical lesson, and still more certainly a pathological one, worth learning. Such lessons are accentuated by the previous careful investigation of the parts removed, and by their subsequent exhibition.

I now come to the matter on which I wish to invite your views to-night—namely, how far does the natural desire on the part of the surgeon to remove as little as possible from the pelvis, militate against the future happiness of the woman and increase the risk to her life? To-night I must strictly limit the field of inquiry to one single group of conditions the surgeon has frequently to deal with, and narrow the discussion down to this. I mean the operative procedures necessitated when we are compelled to perform *abdominal* cœliotomy for adnexal disease. I am not referring to colpotomy, though doubtlesss many remarks I have to make will in a degree bear on the vaginal operation also. A word is necessary with regard to the whole question of cœliotomy for adnexal disease, threadbare as that question is. I shall only touch upon it here as it bears on the subject I am dealing with.

I suppose we all come under one of four heads in our daily actions of life. Though it does not infrequently happen that in the elaboration of the mental impulses of many of us composite forces are at work, still, the preponderating material present in the gradual construction of the character of the man gives to that character the aspect which we denominate and differentiate as knavery, folly, ignorance or honesty. Doubtless, as in geological strata, there are intercalations (transitional and intermediary states) in which one phase of our nature passes by imperceptible gradations into the other—the strata of the knave into the intercallary formation of the fool, or the looser bed of the latter into the solid rock of ignorance beneath.

At times, in searching with our exploring hammer through the complex formation and ramifications of human character, we are too apt to conceive of and seek for in others imaginary and impossible combinations, and, disappointed in the search, to damn altogether the subject of our hypercritical investigation.

You say, "Where in the gynæcological formation does the stratum of honesty come in? Is this species extinct?" The attitude of some suggests to us the answer that the pure quartz of honesty, untainted by any of these more strictly human elements, is only to be found in the gynæcological physician who deprecates operative interference in cases of adnexal disease, and piously talks of mutilation, risk, rest and change of air. To some of us this may have the same resemblance to the *bona fide* substance we are seeking as one of the Faulkner diamonds or genuine old paste has to the real stone, and if we could merge Pecksniff and Micawber into a compound term we might give it that name as a definition. "Pure ivory," said the late Lord Lytton in one of his "Fables in Song," "fares no better than mere bone." And surely the osseous tissue of the genus elephas gynæcologicus is used to serve up on special occasions, and made to do duty as a substitute for the ivory of his tusk. Rare, however (as some would still have the world believe), as it is to find an honest operating gynæcologist, still we may, by a stretch of

---

(*a*) Read before the British Gynæcological Society, November 13th, 1902.

generosity, conceive that a few exist, and I must tax the exercise of your liberality to-night in asking you to concede to me that, however contaminated I may be by the "sacra auri fames," by thirst for reputation, love of experiment, and that professional bias that Herbert Spencer has so well depicted as influencing all professional men, from archbishops and lord chancellors down to gynæcologists, still, I am, as Tennyson puts it, so far as "may be consonant with mortality," honest in the arguments I put before you. Further, I ask you to believe that in some of these I am moving in a direction contrary to my own bias and past beliefs.

I shall place the subject before you thus:—In the first instance, we will ask what is our present position as regards risk to life in abdominal cœliotomy—(*a*) in uncomplicated cases, (*b*) in complicated. By "uncomplicated," I mean plain, straightforward cases in which the operation can be completed without any unusual risks from adhesions, hæmorrhage, the presence of septic fluids, or such a low state of vitality or deficient vital resistance as to render the risk of any operative interference disproportionate to its severity. By "complicated," I understand those cases in which the operator meets with old and extensive adhesions, and organised attachments to surrounding parts, the presence of septic fluids, the prolongation of an operation in consequence of the complications being bilateral, the extra shock involved both by this and possibly by hæmorrhage and difficulty met with in delivering the tumour. To these unpropitious conditions we may add the temperament of some patients, restless, apprehensive, hysterical and impatient of pain. In the first class of case I do not think that it is exaggeration to say that the mortality (with our improved methods) of simple salpingo-oophorectomy is not more than 1 to 2 per cent. For my own part, taking all the cases of salpingo-oophorectomy I have performed (I cannot say how many) complicated or otherwise, I have only lost one, and that I attributed partly to some operative bungling. The patient had been ailing for years; had mitral valvular disease, and was very anæmic. There was adnexal trouble, and it was associated with great agony. In consequence of her cardiac complication I put off operation. At last there was no alternative, save operation, and I removed a blood-sac from the right side, and found another similar sac at the left. Both were bound down by adhesions. In freeing these and in bringing the adnexal mass to the surface I had great difficulty, and was tempted to seize the tumour with a tenaculum. In the effort I must have pierced a large venous sinus in the broad ligament. Immediately the pelvis filled with blood, and I had the greatest difficulty in arresting the hæmorrhage. I left a Miculicz tampon in the pelvis, and a temporary clamp. There was no further hemorrhage, but she never recovered the shock. This has, so far, been my first and last death from salpingo-oophorectomy.

If now we endeavour to determine the percentage mortality in the complicated cases, we have a difficult task. Tait said that oophorectomy might be one of the simplest and easiest, or one of the most difficult, operations in surgery, and so it is. Still, I do not think that we can assign a larger mortality, even in complicated cases, than 5 per cent. Is there any operative procedure of equal severity in the whole domain of surgery of which more favourable results can be quoted than this? I am ignorant of any.

Bear in mind that the great majority of these operations are undertaken for utterly incurable conditions, or, at the best, in states where there are smouldering volcanos ready to burst into activity at any moment under the slightest provocation, and commonly rendering the woman's life a misery to her. This, then, is our position to-day in regard to salpingo-oophorectomy—it challenges competition with any other surgical major operation for rapidity of execution, speediness of recovery, and completeness of cure. Personally, I should let no sentimental considerations or problematical sexual consequences stand in my way of rescuing a woman from misery, or saving her life—she knowing to the fullest the consequences of the step about to be taken and acquiescing in its completion. It goes without saying that gratifying results only follow from the most thorough and complete operations. "The opprobrium of all such operations in the future," said Tait, "will lie in their incompleteness." In another generation or two, when most names in British gynæcology are forgotten, or at the best, remembered only as those of commonplace workers, that of Lawson Tait will be regarded as one of the earliest landmarks in the evolution of this branch of pelvic surgery.

There must ever be a large proportion of cases in which the complete removal of both adnexa is indicated. Cystic and other tumours, pus cavities and sacs, if present, immediately determine this. There is another class in which the examination of the unaffected adnexa on one side proves them to be normal and healthy, *and in which no question of their removal can arise.* There is a third where partial disease affects the tube or ovary, or both, either on the one side or on the two. The question I wish to raise to-night is, How are we to deal with such cases—(*a*) when the organs at either side are sufficiently free from disease to justify attempts at conservative operations; (*b*) when the partially affected adnexa on one side are associated with organs so seriously affected on the other as to call for the removal of the latter.

We will deal with the first contingency. I take it that no one will remove adnexa in whole or part in which such operations as ovarian resection or salpingostomy offer a reasonable hope that a cure will follow their performance. This would apply to simple cystic states, small blood cysts, localised suppurative foci in the ovary, or localised and circumscribed distension and stricture of the Fallopian tube.

Here careful ablation of the diseased parts, and plastic operations, afford the woman all the protection she can expect against a second operation. Should she, however, insist that in the event of its being found that there is a reasonable doubt of such a favourable result following, the adnexa are to be removed, then I think she is entitled to the benefit of that doubt, and should not be subjected to the risk and ordeal of a second operation.

Before I discuss the other class of case, I may here interpolate a few comments on the way in which we are apt to assume to ourselves the privilege of determining, not what women may or do feel in these matters, but what we consider that they ought to feel. I fear that our familiarity with the complaints of women, of pain, misery, domestic incapacity, confinement, and loss of all social pleasure, breeds in us a certain degree of contempt, and that we should view them from a very different standpoint if we ourselves were the victims. We are so accustomed to the marvellous endurance and self-denial, and the power of bearing silently, that women as a rule possess in so much a greater degree than men, that we are apt to grow somewhat callous in making further, and perhaps unreasonable, demands on their fortitude. Possibly the common misuse of such terms as "neuroses" and "hysteria" has something to say to this. How many men would escape the stigma of being classified as "neurotic," or "neurasthenic"—nay, even "hysterical"—cool, brave, and imperturbable though they may be under ordinary circumstances, if they had some abdominal disease for months or years, comparable to any of the diseased conditions from which women often suffer uncomplainingly? How many men would screw up courage to undergo the ordeal of a second, or possibly third cœliotomy? As compared with the majority of operations called for in diseases of the genitalia in women, removal of the appendix is a mere trifle. Also the antecedent effects on the vitality of the sufferer are widely different. Ask any man how he would like to go through the trial of a second similar operation! Look at it how we may, to subject a woman to a second cœliotomy, the apprehension of it accentuated by her experience of the previous one, the unavoidable pain and risk, is a thing to be avoided on all grounds whenever it is possible, and it is our duty to take every precaution to protect her from such a catastrophe. Doubtless there are women who have a craving for operation, a distinct outcome of morbid mentalisation. We have all met examples of such. These are true instances of complex neuroses, in which the genitalia play an important part, but no surgeon will minister to a mind so affected by humouring the morbid whim or impulse by operating.

There is another inquiry that some women make, and one that seriously influences their determination. That is, how far the disease in the genitalia is likely to influence the germs which follow future conceptions? This is a question of great interest. It touches on the problem of hereditary influences, both paternal and maternal, in the pro-nucleus in the ovum. One would like to follow out the life histories of such conceptions, and study the pathological developments in the mature organs, and the correlative mental attributes, latest modifications consequent upon such embryonic influences not necessarily manifesting their presence until adolescence or during adult life. If it is not unreasonable to infer that the ovum must be influenced by the physical and mental state of the woman, whose genitalia have been seriously affected, and by the local morbid conditions, whatever they may be, which may tend to a predisposition to kindred changes in the offspring. For instance, a patient from whom the tuberculous-pyo-salpinx I show was removed eighteen months since, is now in the third month of pregnancy.

The other class of case to which I refer is that where it is imperative to remove the adnexa of one side, and where at the time of operation those of the other are found to be partially affected in any of the ways that I have mentioned.

Is it the best course to perform some conservative operation and return the adnexa, or to ablate them? Here I show the adnexa removed from two patients. The first was operated upon by me on December 9th, 1900, for adnexal disease, and the affected tube and ovary were removed.

The patient was a married woman, æt. 26. The adnexa were shown by me here. Constant and uncontrollable vomiting necessitated operation. All vomiting ceased from the time of its performance, and the patient was apparently restored to perfect health. The cyst on removal was the size of a small orange, there had been intra-cystic hæmorrhage into the tumour. At the same time the opposite ovary was resected, and a fair sized cyst was ablated, while some smaller cysts were punctured. In May, 1902, she contracted influenza, and after this similar attacks of vomiting to those she had suffered from in 1900 commenced. There was also severe headache, and a great pain in her right side. I saw her in July, the sickness having increased, and also the pain. She now had great difficulty in walking, and there was incontinence of urine. On September 15th I performed a second operation, when these adnexa were removed. It will be seen that there was cystic degeneration of the ovary, the tube being distended, and there was a double cyst in the broad ligament. She made a rapid recovery.

No. 2 is from a patient, æt. 32, who was operated upon by another surgeon, an able gynæcologist, five years previously for a hydro-salpinx at the left side; it was the size of a fist, and was removed by a posterior colpotomy. The operation was a simple one. At the time both ovaries appeared on inspection to be healthy, except for the appearance of several small cysts, which were punctured. Both ovaries were returned. The uterus was healthy in size and position. The condition, as reported to me when I saw her in August last was as follows:—Uterus normal, right ovary normal, left enlarged and painful. There was a serious falling off in weight and general health. On examination, I found an adnexal tumour filling the pouch of Douglas. Operation revealed a left ovary and tube fixed and surrounded by adhesions. At the right side there was a cyst about the size of an orange, and an enlarged tube —a hydro-salpinx. The right adnexa were removed and the patient is now quite a different woman, notwithstanding the added complication of a movable and enlarged kidney. The left ovary still discharges its function, though I fear that it will ever be the source of at least periodical trouble.

Here are two operations occurring within a few months, in which a complete operation on both adnexa in the first instance would have saved a second one, also great suffering, if not risk. I have at present under my care three cases in which oophorectomy at one side, resection at the other, and ventro-suspension, were performed by me, and in both there is now an adnexal mass, which I fear will require removal.

The fact remains that no surgeon can tell what percentage of such conservative steps may bequeath a demand for secondary interference. And the very nature of the affections to which these organs are subject (I speak more particularly of the ovaries) renders this recurrence a probability. Nothing is more tempting than to do a neat resection and return an ovary. Nothing is more gratifying than to find pregnancy follow our efforts, and maternity secured. Let me pass round a few substantial evidences (photographs of children) of resection, following ventro-fixation and salpingo-oophorectomy. For one of these cases I am indebted to a gentleman who is here to-night, and who can bear testimony to the patient's miserable state of health at the time of operation (Dr. W. K. Bourke). I only refer to the gratifying result of her complete recovery in order to show that I am fully alive to the other side of the question, namely, the desire to preserve the adnexa at all hazards. There are points not to be overlooked in considering this question. Kindly remember that nothing is further from my desire than to even seem to dogmatise on so important and disputable a point as the one we are here to discuss calmly and without bias. Still, I must candidly say what my own view is. I shall summarise it thus—given a case of adnexal disease demanding abdominal cœliotomy, in which the adnexa of one side are seriously involved, the contingency of partially affected or unhealthy adnexa at the other side should be carefully discussed with the patient, and her deliberately-considered wishes ascertained as to the removal of or retention of these. The possibility of the need for a second cœliotomy should be pointed out to her—the surgeon not merely obtaining what is known as "a free hand," but eliciting her express wish after the clearest possible explanation placed before her of the advantages and disadvantages of both courses. If there is a reasonable doubt of the future health of the adnexa in question, then I think the best course is to remove them, provided always that the patient has given her full consent to such a proceeding should it be deemed necessary.

I have said nothing of certain questions which are closely allied to this one. These are not touched on in this short paper, but concern the relative advantages of the vaginal and abdominal routes in affections of the adnexa-drainage as against radical operation in certain cases of pelvic suppuration (recently again advocated by Noble) or any collateral issues as the consequences of double salpingo-oophorectomy, sexual or other, and I have avoided any allusion to methods of technique in conservative operations on the adnexa. None of these matters, therefore, come under discussion to-night. I trust that you will agree with me in thinking that the subject is one that justifies me in bringing it before you.

ABSTRACT OF NOTES
OF
EIGHT CASES OF GASTROTOMY FOR GASTRIC ULCER, *(a)*

By MANSELL MOULLIN, B.A.OXON., M.A., M.B.

IN six of these cases the operation had been performed for hæmatemesis, and in two for continued pain and vomiting. One patient, who had lost so much blood that she had to be transfused both at the time of operation and subsequently the same evening, died on the eighth day from general peritonitis, due to the contents of the stomach having escaped through the anterior wound, which showed absolutely no sign of repair. The five others recovered. In addition to these, Mr. Mansell Moullin stated that he had been consulted with a view to operation in eleven other cases. In five of these no operation had been performed, and they had all died, three from hæmorrhage, one from perforation, and one from exhaustion. The six others had been operated upon with one death The notes of these had been already published, (*Lancet*, October 20th, 1900, and July 5th, 1902.) Putting aside, therefore, all operations for the complications and sequelæ of gastric ulcer, such as perforation, pyloric and cardiac stenosis, having less contraction, perigastric abscess, adhesions and such like, of the nineteen cases of gastric ulcer in which he had been consulted, the five which were not operated upon died, and only two of the fourteen which were. In eleven of these fourteen the immediate cause of the operation was hæmatemesis, and six of these were so far gone from loss of blood that transfusion had to be performed upon the table or immediately after. Of the two that died, in one the kidneys were badly diseased, and there was an open artery on the floor of the ulcer; in the other, as already mentioned, the loss of blood had been so great that the patient had not sufficient recuperative power left to effect repair of the wound. Everything had gone on well until the fourth day, when the wound in the stomach opened, and general peritonitis followed. In most of these cases the ulcer had been excised, and the wound brought together with fine silk sutures. In two, however, it was simply sutured. In two others, both of which recovered, the whole thickness of the wall of the stomach at the site of the ulcer was strangulated by a silk ligature applied round it from the mucous surface, one or two Lembert sutures being applied in addition on the outer surface; and in one in which the ligature applied in this way could not be made to hold, owing to the softened state of the mucous membrane and the great thickening of the other layers, the wall of the stomach was raised into a fold, which was sutured through and through transversely from the mucous surface, the ends of the contiguous ligatures being tied together, so as practically to effect the same result as ligature of the wall *en masse*. Mr. Mansell Moullin went on to say that he had not the slightest intention of advocating operation in all cases of gastric ulcer, or of anything that would be construed into such advocacy; but that he was certain that if operations were performed more freely, not only would many more lives be saved, but that patients would be saved an enormous amount of suffering. At his request Dr. Bulstrode had collected and analysed the cases of gastric ulcer admitted into the London Hospital from 1897 down to the present time with the view of ascertaining the results of hospital practice. The number was exactly 500, 98 men and 402 women Of these no less than forty eight, or nearly 10 per cent., had died from perforation and peritonitis; thirteen (2½ per cent.) from hæmatemesis, and twenty-eight (5·5 per cent.) from other causes. The total number of deaths was eighty-nine, or, approximately, 18 per cent. These figures, however, were deceptive in that they embraced all the slighter cases on which no one ever proposed to operate. If these were left out, and only the gravest of the grave counted (such cases, for instance, as those in which operation might be contemplated), the percentage would be far higher. Dr. Bulstrode had also calculated that of these 500 cases upwards of 216, or 42 per cent., had been in hospital already for this complaint, and had relapsed. If to the 18 per cent. that die, and the 42 per cent. that relapse are added all those cases in which the later sequelae (such as pyloric stenosis, &c.) occur and those in which cancer develops (estimated by Hauser at 6 per cent.), it must be admitted that the results of the present method of treatment are not so successful as they are usually thought to be, and not nearly so successful as they would be if an operation were performed in the more serious cases, those which would terminate fatally. The indications for operation in acute cases are threatened perforation and hæmorrhage. The former may present no symptoms of any kind until perforation actually takes place The greater part of the wall of the stomach is absolutely devoid of sensibility and may be cut, or pinched, or burnt, without the patient being aware of it. It is only the parietal peritoneum that has sensory nerves, and an ulcer of the stomach does not cause pain until the irritation, spreading from it, affects the parietal peritoneum, under that which lines the under surface of the diaphragm. Pain or pressure, therefore, is not so much an indication of ulcer of the stomach, as that the ulceration is spreading, and is, therefore, likely to end in perforation. One attack of hæmorrhage is not an indication for operation, but a second attack is. Hæmorrhage in ulcer of the stomach, when it is severe, is nearly always caused by a lateral opening in the wall of an artery. Severe capillary hæmorrhage needs proof. If the wall of an artery has given way, the opening may become plugged, and the hæmorrhage never return. But, if it does return, it means that the plug has been dislodged, or destroyed, and it is not wise to expose the patient to the risk of a third attack. In chronic ulcer it is entirely different. The fact of an ulcer having become chronic is proof that the previous treatment has failed. Chronic ulcer is exceedingly serious, not only in itself, but from the complications it entails, and if treatment has been tried thoroughly once, and has failed, there should be no further delay in operating. The mortality from hæmatemesis alone in chronic ulcer of the stomach has been shown by Dr. Wall, from statistics collected at the London Hospital, to be 6 per cent. in women and 12½ per cent. in men. If to this is added the mortality from perforation, exhaustion, the supervention of cancer, perigastric abscess, and the recurring other sequelæ which so frequently set in, it must be admitted that the death-rate is a very serious matter. Mr. Mansell Moullin also drew attention to a kind of case which had hitherto been classed with cases of chronic gastric ulcer, but which should be kept separate, and which he proposed to speak of as recurrent ulcer. The patients in the intervals between the attacks were perfectly well. There was either some condition of the stomach itself, or of the general constitution, which predisposed to the successive development of ulcer of the stomach. What this condition might be was not known; but, until it was known and could be remedied, it was better that gastro-enterostomy should be performed and recurrence prevented by placing the stomach at perfect rest, than that the patients should be left with the risk of hæmatemesis, or of perforation, constantly before them. Instances were quoted in which acute ulcers, which could not have been present more than a week or two at the most, were found, although the symptoms had lasted off and on, with intervals of perfect freedom for several years.

Clinical Records.

OPERATION FOR PERFORATED GASTRIC ULCER —THREE CONSECUTIVE CASES. (a)

By **Robert Bickersteth** F.R.C.S.

Senior Assistant Surgeon, Liverpool Royal Infirmary.

The first patient was a housemaid, æt. 27, on whom the operation was not performed until twenty-seven hours after the perforation had occurred. The ulcer was on the anterior surface of the stomach, but close to the cardiac orifice To get at it at all, it was necessary to completely divide the left rectus muscle, and even then it could only be reached with the greatest difficulty.

The second patient was a man, æt. 23, in whom only four hours elapsed between perforation and operation. The ulcer was on the anterior surface of the stomach, but close to the pylorus. There was no great degree of thickening of the stomach wall round it, and it could be readily closed by a double row of sutures, invaginating a fold of stomach wall at this part.

The third case was a hospital nurse, æt. 30, in whom the operation took place four hours after perforation. Much turbid fluid was found in the abdomen, as was also the case in both the operations previously described —but even after a most careful and prolonged search no sign of ulceration or perforation could be discovered—not only in the stomach, but in part of the small or large gut. A second incision made over the appendix showed both this and the Fallopian tubes to be healthy, and after a thorough washing out, and provision for free drainage from both abdominal incisions, this case had to be sent back to the ward without the perforation ever being discovered and dealt with.

(a) Notes read at Meeting of Liverpool Medical Institution November 6th, 1902.

Contrary to expectation, the woman, after lying in a critical condition for several days, eventually did well, and made an excellent recovery; she was now, two years later, in good health, and busily engaged in her calling.

Of the other two cases, one occurred fifteen months and the other three months ago, and all three cases not only regained their health very rapidly after the operation, but showed a most marked improvement on their previous condition, and put on flesh.

This Mr. Bickersteth attributed to the very careful and rigorous dieting enjoined for many weeks after the operation; the patients, after they had passed through so grave a crisis, readily submitting to measures which, under any other circumstances, they would scarcely have been induced to tolerate.

CLINICAL SOCIETY OF LONDON.

Meeting of Friday, November 14th, 1902.

Mr. Howard Marsh, F.R.C.S., President, in the Chair.

Dr. W. H. B. Brook on cases illustrating the

CLINICAL FEATURES OF AN EPIDEMIC OCCURRING AT LINCOLN IN MAY, 1902.

In the early part of May, 1902, an epidemic suddenly broke out in the city of Lincoln, of which the chief characteristics were :—Sore throat with œdema of the fauces and uvula, the tonsils in many cases being covered with a drab-coloured fur. A dark measly eruption was met with in two-thirds of the cases on the second day, lasting from a few hours to one week, and showing a tendency to recur in some cases as late as the sixth week. In some cases it was of an urticarial character. During the fading of the eruption desquamation occurred in one-third of the cases. The fever was never high unless complications were present, generally under 102°, falling on the appearance of the eruption. The pulse-rate was not increased in proportion to the fever. Albumin was never present in the urine, except in two instances in which at the end of a month there was a transient attack of hæmaturia. Seventy-five cases occurred in the space of seven days in the practice of Dr. Brook and that of his partners, Mr. Charles Brook and Dr. Stanley Green, and in no case did the infection appear to be communicated to others. Nearly all the patients were adults, several were well advanced in years. The complication most commonly met with was swelling and tenderness of the cervical glands, generally about the fourth day; this was accompanied by a return of the fever, which in some cases became very high, and could only be reduced by the administration of anti-streptococcus serum. This inflammation of the cervical glands occurred in some patients who had apparently quite recovered, and in them appeared to be dependent upon a too early return to the meat diet, which also had a tendency to cause gastritis and even peritonitis. Stiffness of the muscles and joints was met with in several instances; in one, an adult, this occurred at the end of a fortnight, and was so marked as to resemble acute rheumatism, the stiffness of the joints persisting for several months. Septic phlebitis occurred in one case, æt. 66, which terminated fatally on the twentieth day, with symptoms of pyæmia, death being ushered in with hemiplegia, coma and convulsions. With one doubtful exception all these patients had had milk from the same dairy, a circumstance which was suggestive of the infection having been conveyed by milk The epidemic was investigated by Dr. Klein, who isolated a special micro-organism from swabs taken from the throats of several of the patients. The treatment that gave the best results was rest in bed with a milk diet. Calomel followed by a saline purge when first the patient was seen, and a simple saline mixture with salicylate of sodium followed during convalescence by the administration of quinine. Great relief was afforded by the application of nitrate of silver to the fauces, and the frequent use of a gargle containing carbolic acid and borax.

Dr. Goodall observed that similar epidemics were not unknown elsewhere, and he referred to an instance in N.E. London in which the infection was thought to have been conveyed in the milk. He pointed out, however, that scarlet fever patients who had bad throats of the anginoid type often developed very curious eruptions.

Dr. E. G. L. Goffe asked if Koplik's spots had been looked for, also whether the usual complications of scarlet fever were absent in all the cases?

Dr. Savill referred to an epidemic which broke out in the Metropolitan Infirmaries in 1891, especially at Marylebone and Paddington. The symptoms were very similar to those described by the author but severer. The eruption became general, and there was a slight tendency to pyrexia. The chief difference lay in the absence in these cases of any throat lesions, at any rate in the milder cases. He thought that possible food supplies might have received more attention when investigating the source of the disease, and it was a significant fact that on talking the matter over with Mr. Lunn, of the Marylebone Infirmary, they found that the only purveyor they had in common was the dairyman. His own belief was that the poison was conveyed in the milk. An epidemic of a somewhat similar kind had occurred at the Greenock Infirmary. Every autumn a tendency to skin diseases was noticed in the infirmaries of London, and he thought this fact required to be investigated.

Mr. John R. Lunn mentioned a most remarkable feature of the epidemic referred to by Dr. Savill, viz., that it lasted six years with one year's intermission. The disease was infectious or contagious, since his assistants and nurses caught it It was investigated by most authorities on skin disease in London. He had seen several outbreaks of a similar character, but they were not as severe. They thought at the time that it was due to the milk. It was remarkable that the disease mainly affected old people. They had not had any other outbreak since, but recently there had been two or three isolated cases, and he had been apprehensive lest they should usher in another epidemic. No treatment seemed to have any effect on the malady, except, perhaps, the application of collodion and iodine.

Dr. Poynton asked whether antistreptococcic serum had been used?

Dr. Brook, in reply, said they had found that boiling the milk prevented persons taking the complaint. The poison seemed to reside in the cream more than in the milk. In only one case was there any otorrhœa, and in that case the erysipelas bacillus was present in the discharge. In one case the cervical glands suppurated. Koplik's spots were looked for in every case, but were never seen. He had injected antistreptococcic serum supplied by Parke, Davis and Co. with most remarkable effects, the temperature falling at once from 105° to 100° F., and this on several occasions They had seen cases of true scarlatina, and the difference was marked.

GASTROTOMY FOR GASTRIC ULCER.

Mr. Mansell Moullin read the notes of eight cases in which he had operated for gastric ulcer, which will be found on page 544.

Mr Barker raised the question as to what ought to be the line of treatment in cases of severe hæmorrhage from the stomach when they had decided to operate. Ought they to open the stomach and look for the point of hæmorrhage, or should they content themselves with relieving the gastric stasis by gastro-enterostomy. He admitted that he experienced great difficulty in deciding this point. There were many cases in which no ligature would hold in the gastric wall, and moreover, in many instances, even on looking for the orifice it could not be found. He recalled such a case in which he failed to detect it after careful search, and even on the post-mortem table they almost gave up the search before a minute aperture was detected.

Mr. **KELLOCK** said they must draw a sharp line between hæmorrhage from the stomach and perforation, the latter, of course, calling for immediate treatment. The author seemed to have operated for the relief of pain and vomiting, but these were not the most urgent symptoms. He thought that the vomiting was often not due so much to the condition inside the stomach as to something outside and around the ulcer. He himself had operated on two patients with these symptoms. One had suffered for seventeen years from pain and vomiting, and on opening the abdomen he found a large scar in the wall of the stomach, and attached to it a tough band of adhesions, which eventually he excised in its entirety. The result was in every respect satisfactory. More recently in another patient presenting much the same symptoms, very anæmic with pain and vomiting, but no wasting, the possibility of hysteria was entertained, but on opening the abdomen he found exactly the same condition of things, the same depressed scar in the wall of the stomach, and adhesions to the parietes, which he divided, simply turning in the wall of the stomach without opening it. This patient had been well ever since. He asked the author why he made another incision in the stomach in one of his cases instead of attacking the depressed scar from the outside.

Mr. **BIDWELL** asked whether adrenalin had been used, and mentioned the case of a patient who had severe hæmorrhage after gastro-enterostomy, which was relieved by this drug. In the milder cases he thought this drug should be given a trial.

Mr. **MANSELL MOULLIN** in reply, re-called a case in which gastro-enterostomy had been performed, and the hæmorrhage had continued, indeed, he did not see how it could be otherwise. In the case referred to by Mr. Kellock, he had closed the anterior incision in the stomach by two rows of sutures, but the patient was so debilitated that no attempt at healing had taken place. If the sutures in the posterior incision did not give way, that was probably because, comprising as they did much more tissue, sufficient time had not elapsed to allow of this taking place.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

PATHOLOGICAL SECTION.

MEETING HELD FRIDAY, NOVEMBER 7TH, 1902,
PROFESSOR **BENNETT** in the Chair.

PROF. E. H. **BENNETT** exhibited specimens of

DISLOCATION OF SHOULDER,

and read a note on some cases in which Kocher's method of reduction of dislocated shoulder has failed. The specimens were a dissection of an old unreduced dislocation, which in all particulars conformed with Malgaigne's definition of subclavicular dislocation; and a cast of the limb exhibiting the characteristic features of the injury. The cases recorded were two from the living; one seen on the day of the injury, the second, five weeks after. In the first an attempt at reduction had already failed, made by very competent hands. The second was five weeks unreduced, and had been five times submitted to attempts at reduction under anæsthesia. The injuries conformed in their features with the subclavicular dislocation of Malgaigne, in both Kocher's manipulation and the method by the heel in the axilla failed. The reduction was in both obtained by traction with rotation on the arm abducted downwards and outwards. Professor Bennett discussed the influence on the reduction of the character and position of the lacerations of the capsule.

Dr **KNOTT** said he would like to ask Professor Bennett to explain why he considered Kocher's method so much superior to horizontal and upper vertical extension?

Professor **BENNETT**, in reply, said the reason Kocher's method is so useful is that it applies particularly to the intra-coracoid dislocation, which is the most common, or its immediate modifications. He had never met with a case which resisted Kocher's method, except the two he had described.

Dr. **EARL** showed a case of

ADENOMA OF THE LIVER.

In describing the case, Dr. Earl said the liver showed the most marked synotic atrophy he had ever seen. His attention was drawn to a small, round mass, well marked off, and of a green colour. The liver contained a large number, fifteen or twenty, of these, and most probably there were more. The largest was about half an inch in diameter. The liver itself had altered in appearance and the histological characters of these masses were hard to make out, none of them abutted on the surface, and consequently his attention had not been drawn to them. The cells in them bore a close resemblance to liver cells. They were divided into lobules, and were surrounded by a fibrous capsule. The cells were arranged after the manner of normal liver cells, but with less regularity. He found coagulated bile present, and there was a great deal of granular bile-pigment in the liver. Sections of some of the smaller tumours showed more marked resemblance to normal liver structure. These tumours appeared to be one of the forms of adenoma. He presumed that synotic atrophy of the liver had nothing to do with these.

Dr. **DAWSON** asked Dr. Earl whether this liver showed signs of malignancy? He had seen in Vienna two cases of adeno-carcinoma of the liver which resembled these.

Professor **O'SULLIVAN** said he would like to ask Dr. Earl if there was any difference between the cells in the liver and normal liver cells? He had a case of extreme cirrhosis of the liver in a young girl, in which there were growths through the liver, when the cells were larger than normal and less regularly arranged. He looked upon this as regenerative.

Professor **WHITE** said the question of whether this was an adenoma of the liver or an adeno-carcinoma must be left to Dr. Earl. He was inclined to agree with Dr. Earl that it was adenoma from its microscopic characters, and also as he felt sure that Dr. Earl would not have given it the name of adenoma if secondary growths were found. He said Dr. Scott had shown some time ago a case of a large single adenoma of liver.

Dr **EARL**, in reply, said that with regard to what Dr. Dawson had said he felt certain that they were not malignant tumours There were no growths found anywhere in the liver, and the fact that the resemblance to normal liver cells was so close, would negative the view that the tumours were malignant With regard to Dr. O Sullivan he said he did not see any great difference between these cells and normal liver cells. As to whether there was an attempt at regeneration, that could not be decided.

CAVERNOMA OF THE LIVER.

Dr. **EARL** said that this was a well-recognised and not uncommon condition which occurs in human beings and in the lower animals. Cavernomas were sometimes single, but generally, as in this case, multiple, and usually occurred in elderly people, though sometimes they were seen at a very early age, even in infants of a few weeks old. They appeared of a dark purple colour on account of the contained blood, and were of various sizes. They might be as large as an apple. They were not raised above the surface of the organ when they abutted on it, and they were also found in its substance. Their structure resembles that of the cavernous tissue of the penis. Simple muscular tissue is said to occur in their walls. In some cases liver cells have been found in their walls. The larger tumours are surrounded by a fibrous capsule; the smaller merge in the liver substance without any capsule. Though the condition is well recognised, there is considerable doubt as to their pathogenesis. They have been considered tumours, but they never cause any enlargement of the liver. They are merely substitutions of the liver tissue, and are generally believed to be due to dilatation of lobular cavities with subsequent pressure atrophy. Tumours very similar to these have been produced in cats by causing narrowing of the hepatic vein. The fact that liver cells are found in the walls is in favour of their origin from pre-existing capillaries in these places.

Professor Scott exhibited

AN EPITHELIAL TUMOUR OF THE GALL-BLADDER

removed by operation by Mr. Heuston. There was a large mass attached to the gall-bladder, which was swollen. There were calculi in it and in the surrounding tissues. A section showed it to be of undoubted epithelial origin. Most of the cells were undergoing a mucoid degeneration.

Mr. Arthur Benson and Dr. Earl showed a case of

CONGLOBATE TUBERCULOUS TUMOUR OF THE CHOROID

in a girl, æt. 14. The growth, which only dated from March 27th, 1902, occupied almost the whole interior of the globe, the vitreous being pushed to one side and the lens remaining transparent throughout. This variety of tuberculosis of the choroid was stated to be a very rare affection, whilst the miliary variety was comparatively common. In this case another remarkable circumstance was noted, viz., that there was no tuberculous family history, nor was there any other focus of tuberculous disease to be found in any other part of the patient. The sections, which were made by Dr. Earl, showed that caseation had taken place in the tumour, and giant cells were also visible. The growth was adherent to the sclerotic in one place, and the retina was wholly detached. The other eye was normal, and the child, though naturally frail, seemed to be in excellent health.

Dr. Earl said that on cutting into the eye he found the vitreous chamber almost completely obliterated by a whitish mass, and he could see a couple of opaque spots even with the naked eye. On examining this mass he found it was strongly adherent to the sclerotic at one point, and at no other. It was a tuberculous mass with a small quantity of caseation. The ciliary processes and the iris were quite free. The layers of the retina were to be seen.

Mr. Story said the case reminded him of a specimen which he had exhibited some two years ago. It was one of a solitary tuberculous tumour in a young woman, æt. 18 or 20. It was in the optic papilla, and simulated the choked disc of intracranial disease. The growth in this case was retinal rather than choroidal.

The meeting then adjourned.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, NOVEMBER 6TH, 1902.

The President, Rushton Parker, Esq., F.R.C.S., in the Chair.

Dr. Grossmann showed a case of

CONGENITAL ABSENCE OF THE IRIS

in both eyes, the only one of the kind he had ever seen. The patient was a young man, æt. 26. The formation of the head was normal. The corneæ were normal, and the anterior chamber of normal depth. The iris completely absent in both eyes The lenses slightly greyish, in both an anterior polar cataract, and a smaller posterior one. There was no trace of ciliary processes visible, not even after eserine. No change in zonula. No photophobia. Vision in both eyes = $\frac{1}{6}$ with + 7 sph. and + 2 cyl. vert. Dr. Grossmann said he intended to examine the lenses for the purpose of seeing whether any support could be found either for Helmholtz's or Tscherning's theory of accommodation.

Messrs. Richard Williams and Stevenson spoke, and Dr. Grossmann replied.

Dr. Burton reported a successful case of

CÆSAREAN SECTION IN A RHACHITIC DWARF.

He said that if the operation was to be a success it must be undertaken as an operation of election, and not as a last resource. Every medical man at the present day ought to recognise at his first examination of a woman whether a living child can pass through the pelvis or not If any doubt existed, attempts to deliver through the pelvis were unjustifiable, as thereby a later necessary operation might be seriously handicapped. In this particular case no doubt existed, the conjugate measuring not more than an inch and a-half. Dr. Burton especially noted the use of an intra-uterine gauze drain, and suggested as a further advantage its action as a uterine stimulant. Finally, Dr. Burton said he had attempted to procure utero-parietal adhesions after Dr. Wallace's method.

Dr. O'Hagan, as a general practitioner, agreed as to the possibility of deciding on a first examination in cases of marked contraction of the pelvis. He pointed out, however, that the greatest difficulty arose in cases in which the conjugate, although it approached the normal, was still relatively to the size of the fœtal head too small. Personally, he preferred the practice of the induction of premature labour at seven to eight months.

Drs. Gemmell, Stokes, and E. T. Davies spoke, and Dr. Burton replied.

Dr. Lloyd Roberts related a case of

GLIOMA OF THE CEREBELLUM WITH INTERMISSION OF SYMPTOMS.

A woman, æt. 29, had double optic neuritis, headache, and vomiting, patellar reflexes absent. The symptoms of intracranial pressure increased, clonic spasm of limbs, inequality of pupils, paralysis of the left sixth nerve. She emaciated rapidly and became comatose. After two months in this state, she began to improve and ultimately became perfectly well except for blindness from optic atrophy, and absence of knee jerks. The patient remained well for eight months, when a return of the symptoms proved fatal, iodide of potassium this time proving of no avail. P.M. A glioma was found occupying the whole of the middle lobe of the cerebellum.

Dr. Gullan said he had seen an almost parallel case, also a cerebellar tumour. In this, however, no return of the symptoms had occurred, but blindness, due to optic atrophy, persisted.

Drs. Warrington and Macalister also spoke, and Dr. Lloyd Roberts replied.

Mr. R. C. Dun showed

TWO UNUSUAL CASES OF SPINA BIFIDA.

The first patient, a girl, æt. 6, had a lumbo-sacral spina bifida from birth. She was run over by a milk-cart, and the spina bifida disappeared entirely without any external escape of fluid. Fourteen days later a swelling appeared over the left dorsum ilii; a few days later the old spina bifida reappeared. From the time of the injury there was marked pain in the back, with partial bladder paralysis. On operation, the old sac was found to be abnormally thick; a small opening at its left side led into a very thin sac closely adherent to the overlying tissues. The adherent nerves were returned to the spinal canal and the sac excised. Result: Cure of the spina bifida, complete loss of pain, bladder paresis unchanged. The second case, a girl, æt. 7, had a lumbar spina bifida occulta, overlying which was a hair-field 6 ins. by 3¼ ins. with hair 7 ins. long.

The President commented upon the curious result of the accident, and said he had a very similar case to Mr. Duns' second patient under his own care.

Mr Robert Bickersteth read a note on operation for perforated gastric ulcer, based upon three recent cases, which will be found under "Clinical Records."

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD THURSDAY, OCTOBER 23RD, 1902.

Dr. John Robertson, President, in the Chair.

Dr. Arthur Hall showed (1) (for Mr. H A. Mason) a case of congenital jaundice in a girl, æt. 13. The child was noticed to be jaundiced at birth and has remained so ever since. Except that she was backward in development and especially in walking, she has always had good health, and is now bright, active, and intelligent, though perhaps a little young for her years. The conjunctivæ are deeply jaundiced, the urine contains a trace of bile pigment and the fæces are fairly well coloured.

(2.) A case of secondary syphilis with severe headache and periosteal nodes on the forehead. The date of primary infection could not be obtained, but the patient gives a history of five weeks' headache. There is roseola. adenitis, cachexia, pharyngitis and laryngitis.

(3.) Case of urticaria with well-marked dermographia.

(4.) Case of disseminated lupus with lichen scrofulosorum and patches of verrucous lupus.

(5.) An old man with extensive rodent ulcer of thirty years' duration, in whom the right orbit and root of the nose is completely destroyed.

(6.) A severe case of seborrhœic dermatitis.

Mr. **Snell** related particulars of (1) a case of complete avulsion of the eyeball by midwifery forceps; (2) a case of palsy of the upper movements of the eyeballs. Recovery. He also introduced (1) a case of acromegaly with bi-nasal hemianopsia; (2) two cases of unilateral congenital hypertrophy of eyelids and face; (3) two cases of monocular blindness following fracture of the skull; (4) two cases of symblepharon, treated by Thiersch grafts. Stereoscopic photographs of cases were shown.

Dr. **Godfrey Carter** showed a case of bilateral clonic spasm of facial muscles. The patient was an engraver, æt. 68. Two years ago clonic spasm of orbicularis muscles followed slight eczema of eyelids and has gradually got worse since. When at close work the spasm ceases, but it is often so severe when out of doors that the eyes are completely closed, and crossing a street is dangerous.

Dr. W. T. **Cocking** showed a case of well-marked jaundice in a woman, æt. 50, which appeared at the age of three weeks and has persisted until the present time.

Dr. **Hall** also read a paper on "Some Cases of Blue Discolouration of the Toes (so-called Cyanidrosis)," in which the staining was due to a blue aniline dye used in the manufacture of cheap black stockings. This is dissolved out by the acid sweat of the feet, and stains the upper layers of the stratum comeum to some depths.

France.

[From our own Correspondent.]

Paris, Nov. 6th, 1902.

Gastric Ulcer.

The treatment of hepatic colic by olive oil internally is of ancient date, but Prof. Mathieu, of Paris, by a series of experiments, has come tot he conclusion that the same treatment is highly beneficial in cases of stenosis of the pylorus, and in chronic gastric ulcer, where an excess of acid existed.

The olive oil possesses a considerable nutritive value, and besides does not provoke gastric fermentation, as is observed with the lactic regimen.

The amount of the oil ingested daily was about 5 ounces, given in three doses. The patients seemed to take it without much reluctance, and after about a week of the treatment the painful gastric symptoms had disappeared.

Obesity.

To persons suffering from obesity with accummulation of fat in the lumbar and abdominal regions M. Kisch, besides the usual diet treatment, recommends local friction with the following ointment:—

Iodide of potassium, ʒj;
Iodine, grs vi:
Vaseline, ℥j.

To be rubbed in night and morning over the lumbar region, and the parts covered with a large compres steeped in a solution of acetate of aluminium:—

Acetate of lead, ʒij;
Alum, ʒss;
Water, ℥viij:

and a sheet of oil silk or other impermeable tissue outside the compress.

For friction of the abdominal walls M. Kirsch replaces the ointment by

Vinegar of squills, ℥viij;
Iodide of potassium, ʒij.

The Population in France for 1901.

According to official reports, the births for 1901 exceeded the deaths by 72,000, while the preceding year the mortality was greater by 26,000. The above result is mainly due to an increase in the number of births and an important decrease in the mortality.

Examining the figures in another order of ideas, it is found that proportional increase represented 0·19 per cent. of the population, whereas for the previous decade it had not exceeded 0·06 per cent. However, the situation of the country as regards the increase of its native population remains always unsatisfactory in spite of the increase registered for 1901, as it only represents 0·07 per 100 inhabitants.

Germany.

[From our own Correspondent.]

Berlin, November 15th, 1902.

The *Deut. Med. Zeit.*, No. 89, has a reference to an article on

The Operative Treatment of Graves' Disease,

by Dr. L. A. Diwawin. From his study of the literature, and from the observation of a number of cases of his own, the author arrives at a series of conclusions, of which the following are the essential ones:—In serious cases in which medicine and electrical treatment have alike failed, operation may afford relief or even effect a cure of the disease.

Medical treatment usually affords only temporary relief, and does not prevent recurrence, but operation secures permanent improvement, in which there are no relapses. The operation cannot, however, be regarded as one free from danger. For its performance general anæsthesia must not be made use of. After operation the treatment must be as careful as possible. Fresh air, good simple feeding, and perfect rest are indispensable.

Those operations are the most suitable that lead to a diminution in the volume of the diseased thyroid gland. There is no routine method of operating and there can be none, as the clinical features of the disease and its pathological substratum are not simple but manifold.

In the surgical section or the Naturforscher Congress Hr. Kehn made some retrospective observations on

Seven Hundred and Twenty Laparotomies for Gall-stone,

with special reference to hepatic drainage. He admits that in many cases of cholelithiasis a permanent resting stage may be brought about by rest cures alkalies, &c. A course of treatment at Carlsbad or Neuwahr will often effect so much that operation is not called for. He doubts, however, whether the actual recovery takes place, *i.e.*, whether the stones are really expelled. It should not be the aim to expel them but to keep them quiet in the gall-bladder and to prevent inflammatory attacks. The long-continued use of hot applications, along with rest in bed and Carlsbad water, does best service in this direction. In case of recurrent attacks of colic without icterus operation is justifiable. Hydrops and empyema of the gall-bladder were surgical affections. Gall stone cases that have become addicted to morphia should be operated on.

Patients with chronic icterus that is not dependent on stone and incurable disease of the liver should be operated on within at least three months after the onset of the jaundice, as, instead of the suspected carcinoma of the head of the pancreas, a curable chronic interstitial pancreatitis will often be met with. But even when no local swelling of the gall-bladder or liver can be found, in case of painful symptoms that resist treatment, operation should be resorted to. In such cases, especially in men, adhesions of traumatic origin are frequently met with without calculi.

It was not possible to formulate general indications for operation. Each case must be decided by itself. Men, especially fat ones, bear operations badly. Women who have borne children bear operations well. The poor must be operated on sooner than the rich, as they cannot afford the benefits of a Carlsbad course, and live carefully. In cases of diabetes, arterio-sclerosis, chronic nephritis, diseases of the heart and lungs, operation should be avoided as much as possible.

Hr. Körte, Berlin, gave an account of 135 cases of the kind operated on by himself.

Hr. Landerer spoke on

THE OPERATIVE TREATMENT OF PULMONARY TUBERCULOSIS.

Like Spengler and others, he had endeavoured to improve cases of cavities and abscesses of the lungs by resection of the thorax He had operated in six such cases with partial or very good results. As regarded the operation, the region of the heart and great vessels was to be avoided, as here pulsatory cicatrices always resulted. Tuberculous tissues should be touched as little as possible for fear of miliary tuberculosis. Stationary cases would give better results than acute ones. Cases of tuberculosis of the lower lobes, the worst for internal treatment, were specially suitable for operation. The difficulty of healing of almost all tuberculous affections, whether of the lungs or joints, lay in the impossibility, or at any rate the extreme difficulty, of obtaining cicatricial contraction. This was seen in coxitis, that healed at last suddenly but with deformity when separation of an epiphysis or spontaneous luxation took place.

Hr. Hofmeister related a case of non-tuberculous cavity of the lower lobe that confirmed what Mr. Landerer had just stated; by resection of ribs cicatricial contraction was rendered possible.

ASPIRIN

is described as an excellent analgesic by Dr. Armin Suess (*Med. Blatt.*, 40/02), and is not only a specific in rheumatic conditions, but is effective in nearly all painful conditions, even those due to new growths. The taste is not disagreeable. No disturbances, such as noises in the head or gastric troubles, have been noted as caused by it.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, November 15th, 1902.

THE bloodless reduction of congenital dislocation introduced by Professor Lorenz is well known to orthopædic surgeons, but it may be well to briefly describe it. The first step in the operation consists in the reduction, the head of the dislocated thigh being brought to the level of the acetabulum. The patient is anæsthetised to an extreme degree of muscular relaxation. A band is passed round the perineum and another around the ankle, the latter being attached to a screw-extension apparatus. The extension is evenly exerted, the operator meanwhile grasping the muscles of the thigh, manipulating them while extension is going on. When the head of the femur is brought below Nélaton's line extension is suspended, and is followed by the second step in the operation—the wedging of the reduced head of the thigh-bone into the acetabulum. This is the repetition. The chief anatomical barrier is the anterior part of the fibrous capsule which hugs closely the surface of the acetabulum. Although the head is in the proper position to enter the acetabulum, no amoun of force will drive it in. The operator, standing on a stool, seizes the thigh, flexed at right angles to the trunk, with one hand, and with the other grasping the head of the femur, he, by a system of extension, combined with rotation and gradually increased abduction, opens the way into the potential acetabular pocket. If the reposition is successful, the head of the femur is felt to leap over the posterior edge of the acetabulum, and the surgeon feels at once that reposition has taken place. The third and final step in the operation has for its object the formation of a solid acetabulum. By manipulation the soft parts of the acetabular cavity may be moulded, but the essential changes occur after the patient is allowed to get about. In order to retain the head of the bone in contact with the acetabulum, and thus re-awaken the process of growth so long dormant, the thigh is flexed in abduction at an angle of about 90°. The position is maintained by the aid of a plaster-of-Paris bandage carefully applied about the pelvis, and extending to the knee-joint of the affected side. After a few days the child is urged to walk. Every step tends to drive the head of the bone deeper and deeper into the acetabulum. Growth is re-awakened, the parts are again rendered active, and a neo arthrosis is gradually built up. Formerly Lorenz removed the first fixation apparatus at the end of three months, and usually subjected the patient to a second fixation period of three months. He now advocates rather longer fixation periods.

INFANT MALFORMATION.

Halasz, at the "Gesellschaft der Aerzte," showed a five days' old child with hare-lip, cleft palate, shortening of the right forearm, subluxation of the elbow joint, and absence of the ring and little fingers of the right hand. The other seven children of the family presented no departure from the normal.

PEMPHIGUS NEONATORUM.

Weiss brought forward a sixteen days' old child with pemphigus neonatorum in the early stage of recovery, presenting all the appearances of a transitional form of dermatitis exfoliativa, the desquamation extending far beyond the limits of the vesicle.

Knöpfelmacher related the history of two cases which had come under his own observation where pemphigus neonatorum, dermatitis exfoliativa, and impetigo contagiosa were associated. One of the sufferers died a few days after birth, as the pemphigus was speedily followed by the dermatitis. The second case was one in which the pemphigus was followed by impetigo contagiosa.

Paralysis of Right Facial and Abducent Nerves.

Schlesinger showed a patient to the Society with complete right side paralysis of the facial and abducent nerves. When the patient was told to look to the right the left globe remained immobile in convergence. There was no congestion of the papilla or fundus, though sometimes there was headache and vomiting. The left facial nerve gave the reaction of commencing degeneration when tested electrically.

From these complex symptoms he attempted to demonstrate by means of a cerebral model that the cause of this paralysis was due to a glioma or cerebral tumour in the floor of the fourth ventricle, or possibly extending from the quadrigemini along the aqueduct of Sylvius.

The Operating Theatres.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.

Peritomy by the Electric Cautery.—Mr. H. Work Dodd operated on a man, æt. about 20, who had been admitted suffering from chronic cyclitis in the left eye. The eye had not been well during the last three years, and during that period he had had exacerbation of inflammation. The vision was good, and the iris was not bound down by many adhesions. The eye ached a little continually, there was a little photophobia and some tenderness; the condition was probably rheumatic in origin. The pericorneal area and the neighbouring sclera were injected with blood vessels, and that part of the sclerotic corresponding to the ciliary body was much darker in colour than elsewhere. The patient having been treated at other hospitals by the usual medicines and applications appropriate to the case (so far unsuccessfully) Mr. Dodd thought more vigorous means might be adopted for the man's relief. He said he first thought of removing a circular piece of the conjunctiva and sub-conjunctival tissue down to the sclera from all round the cornea—the classical operation of peritomy—but ultimately, deciding that a greater degree of counter-irritation should be produced, and a larger amount of tissue dealt with than is the case in the usual operation of peritomy, he determined to operate by means of the electric cautery instead of using the knife. After the patient had been anæsthetised, and the eyelids held apart by a speculum, the cautery was applied to the eye in the following manner: The instrument used had a flat spade-like point something under a quarter of an inch broad; this was heated to a dull red heat, and the eye being held with fixation forceps, a whole area all round the cornea, but carefully avoiding that structure, was thoroughly burnt right down as nearly as could be judged to the sclera; this was extended in such a way as to completely occupy externally the position opposite to the ciliary body inside the eye. A little vaseline was put into the conjunctival sac and the eye bandaged and the patient sent back to bed. Mr. Dodd pointed out that the effect he aimed at was very much that which is obtained by the veterinary surgeon in firing a joint. He drew attention to the fact of the thoroughness, depth and breadth of the application of the cautery to the area treated; the effects he hoped to get from this would be, he considered, much more efficient than those which could be obtained from the milder operation of peritomy, which acted chiefly by cutting off the superficial blood supply to the cornea; but, in the operation he had just performed, counter-irritation with regard to the ciliary region was what he aimed at, and that was his object in extending the cauterisation thoroughly all round the ciliary area. To burn down to the sclera, and even to superficially touch the sclera itself, was, he thought, very necessary; but, of course, penetration of the globe of the eye was to be carefully avoided.

It is satisfactory to state that the patient left the hospital about a month after completely well, and when seen some months afterwards there was no evidence of any of the past disease, and the area treated by the cautery looked practically normal.

THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

Operation for Ovarian Hernia, with Twist of Pedicle and Necrosis.—A baby, æt 12 months, was brought to Mr. Stansfield Collier's out-patient room at the hospital on account of a swelling in the left groin. The mother gave the following history:—For six months the baby had had a rupture on the left side, which had been kept back by a truss; four days previously she had found it impossible to push back the rupture; the day before a doctor made an endeavour to reduce the swelling under chloroform, and, not succeeding, had advised immediate admission to hospital. The child had been in pain, and had not slept properly, but had not vomited, and the bowels had acted daily. The baby looked ill. The swelling was situated over the external abdominal ring; its outline was not well defined; the integuments and the left labium majus gave the appearance and feel of solid œdema; over the middle of the lump elasticity was well marked, but not definite fluctuation, nor was there redness. Mr. Collier remarked that at the first glance it appeared probable that the swelling would prove to be an abscess from an infection of a lymphatic gland, but the history pointed to a hernia, and he related three cases of swellings in the groin of babies which had lately been under his care, in all of which œdema of the integuments had been a marked feature: the first proved to be an abscess from disease of the appendix in a hernial sac; the second a twisted pedicle of an ovary, and the third a twisted cord of an imperfectly descended testis. Mr. Henry Curtis, at Mr. Collier's request, operated, making an incision over the upper part of the swelling, and exposed a necrotic ovary which lay in a sac destitute of fluid. The twisted pedicle was composed of the Fallopian tube and the broad ligament close to the ovary. Mr. Curtis transfixed and tied the pedicle above the twisted portion. The ovary and the free end of the Fallopian tube were enormously swollen and black, but still firm and free from smell. The sac was dissected out and the neck ligatured, the wound was sewn up and a collodion film applied. From this case may be learned, Mr. Collier remarked, that one must not lay too much stress upon œdema of the integuments as evidence of an abscess in the groin, and that tense or painful swellings in the groin should be explored without delay.

REGISTERED FOR TRANSMISSION ABROAD.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 19, 1902.

THE TREATMENT OF GASTRIC ULCER.

IN spite of the great advances which have been accomplished in abdominal surgery the surgical treatment of gastric ulcer is still far from satisfactory. So much is this the case that surgeons display no desire to relieve physicians of the responsibility of dealing with patients suffering from this always grave and often fatal lesion. One reason for this, no doubt, is that gastric ulcer owes its origin in large measure to an underlying condition of physiological misery which reduces the reparative forces of the organism and deprives physicians and surgeons alike of that *vis medicatrix naturæ*, which, in other departments of medicine and surgery, is their mainstay. The etiology of the formation of gastric ulcer is ill-understood, but when the ulcer has actually formed we know by experience that it is very apt to recur. It would seem that even when, under suitable treatment, healing of the ulcer has taken place, the cicatricial tissue which remains is unable in all cases to resist the corrosive action of the gastric juice, so that under comparatively slight stimuli fresh ulceration takes place. In view of the uncertain results which follow surgical intervention in these cases the most serious and urgent cases only are thus dealt with, and the mortality is consequently very high. The anatomical conditions are such as often to frustrate the surgeon's best endeavours and leakage is extremely difficult to prevent. It is necessary to draw a sharp line of demarcation between ordinary cases of gastric ulcer in which pain and vomiting are the principal symptoms, and those in which violent hæmorrhage or perforation places the patient's life in imminent jeopardy. In the present state of surgical technique the former are best dealt with medically, but in the latter the surgeon is compelled to intervene if only to give the victim one last chance of recovery. On the other hand, so long as surgeons confine their ministrations to cases verging on the moribund, so long is gastric surgery likely to remain the opprobrium of the art. Gastro-enterostomy has been suggested and practised as an alternative to opening the stomach, but it is obvious that this operation, although it may remedy the gastric stasis which is associated with this condition, cannot have much effect in arresting hæmorrhage. One reason why surgeons are so chary of operating for the relief of hæmatemesis is that even with the stomach open to inspection it is often a matter of quasi-impossibility to discover the particular point from which the blood escapes. The erosion may be so small as almost to defy recognition, yet by the constant hæmorrhage to which it gives rise it undermines the constitution, and if left open ultimately determines death from asthenia. Ulceration short of perforation, as has been pointed out, may sometimes be effectually dealt with by ligatures applied from the outside, advantage being taken of the opportunity to dissect away adhesions which have formed to adjacent tissues. It is to these adhesions that the persistent vomiting and pain are in great measure due. It is to be hoped that surgeons will not be discouraged by the qualified success which at present attends their efforts. The domain of gastric surgery is still open, and the technical difficulties, which at present mar the success of operations, may prove amenable to new and improved methods. Gastric ulcer is a lesion which obviously calls for surgical relief, and it is one, moreover, the treatment of which physicians would willingly relinquish in favour of less tedious and more trustworthy methods of dealing with than those at their disposal.

THE ELECTRICAL TREATMENT OF CANCER.

OF recent years the developments of electricity have been so rapid that our knowledge of the subject has to be frequently revised from the medical standpoint alone. A field full of therapeutic promise, for instance, has been opened up in the treatment of malignant disease, a point to the consideration of which the following remarks will be confined. As everyone knows, the etiology of cancer is still in the air, although the drift of modern opinion has veered round more and more towards the belief that an animal micro-parasite constitutes the *fons et origo mali*. From the point of view of the practical man of medicine, however, a doubtfulness of that kind does not in the least interfere with his steady pursuit of means which, although empirical, will aid him in the relief and the cure of cancer. The operative surgeon has been enabled to record some measure of success in the treatment of early cases in favourable positions of the body, but his field is so strictly limited as to apply to a small percentage only of persons attacked by the disease. In summing up the position, it may be said briefly that both medicine and surgery have hitherto failed to obtain any mastery over this scourge of humanity, which is no less widespread than deadly. The advent of any new method, then, naturally arouses keen interest in the medical world, especially when it arises in connection with an agency that has already achieved wonders in many other directions, to wit, electricity. Hardly had the medical world fairly grasped the practical importance of the Röntgen ray methods in the fields of medicine and surgery than they were confronted with a fresh marvel, namely, the therapeutic effects of exposure to the focus-tube whence the rays were emitted. Here, again, in the lack of more exact knowledge, curative effects were the fruit of empirical observation. As a matter of fact, the cause of the therapeutic result is no more known in 1902 than it was some five years ago, when these observations were first published. No one can say with authority, for example, whether the X-rays themselves are directly and actually concerned with the curative effects following exposure to the focus-tube. Under these circumstances it seems logical to use the non-committal terms adopted by one observer, who suggests the substitution of "focus-tube" for X-ray, as in the phrases, "focus-tube therapeutics," "focus-tube dermatitis," and so on. The matter is of some little importance, as it is to this agency we are looking with hopefulness in the treatment of cancer. Repeated success has been reported in the case of epitheliomata and other surface lesions of a malignant nature, especially in carcinomatous nodules recurring in the scars left by operation. Further, at least one deeper seated growth is said to have disappeared under the influence of the rays, but for the present we must remain content with the fact that we have found in the focus tube an additional agent of great power and value in the treatment of malignant invasions on the surface of the body. There is yet another modern form of electricity, however, which promises to outstrip not only the focus-tube, but all other non-surgical methods hitherto devised for the cure of cancer, namely, the application of currents of high frequency of interruption. Ever since the discovery of d'Arsonval, that such currents could be passed into the body imperceptibly, medical electricians have been busy with their investigations. The present position is remarkable with regard to cancer. It may be said that in suitable cases patients improve in weight, general nutrition, loss of pain, and regaining of sleep and appetite in a way that has not hitherto attended any other method. At the same time, in some cases at least, the new growth has disappeared and the patient has been apparently restored to health. It is too early to say as yet whether a permanent cure has been obtained in these cases, but at any rate therapeutic results have been secured which are of the highest palliative value. Further developments of this new method will be awaited with the keenest anxiety. Meanwhile, in spite of our present imperfect comprehension of the principles involved and their clinical application, there can be little doubt that in the focus-tube and the high-frequency apparatus scientific medicine has found two potent weapons in her future warfare against one of the deadly foes of mankind.

SOCIETY JOURNALISM AND THE MEDICAL PROFESSION.

Sir William Broadbent's protest against "Spy's" caricature of him in our contemporary, *Vanity Fair*, will raise in many minds a doubt as to whether a sense of dignity and the duties of medical etiquette cannot be carried to too great an extent. It will seem to some people to be perhaps just a little absurd to object to a publicity which has been forced in many instances upon the most prominent and distinguished men in the Kingdom, and in point of fact upon the most distinguished of all. "Spy's" caricatures are known all over the world, and there are, we fancy, few who ever considered them to be actuated by malice, or to be anything save a caricature, in the best sense of the term, of a prominent man. This being so, we fancy that Sir William Broadbent's indignant repudiation can hardly be due to a mere sense of affronted dignity, and the question arises, What is it due to? A man in Sir William Broadbent's position would not send a protest to the Press unless he had a good reason for protesting. The reason is perhaps not difficult to find, if one happens to be a reader of the columns of our contemporary. The fact of the matter is—and we fancy that it lies at the root of Sir William Broadbent's action—the attitude of *Vanity Fair* towards the medical profession is one of carefully-studied insult. In almost every issue of the paper some paragraph appears which represents an attempt to depreciate the medical profession in the eyes of the public. It is not so long since an anonymous member of its staff termed Sir William an "ignorant apothecary," and the reason for this gutter-press invective was that its subject attempted to save the public generally from becoming the victims of one of the many imaginary cures for consumption. Further, in the very number of *Vanity Fair* in which appears the caricature complained of, there is one of a series of articles on medical specialists which, even after every allowance has been made for attempts at humour and the exigencies of shortness of "copy," can admit of no other interpretation than that the series was meant to draw contempt on the medical profession. There is as much difference between *bona fide* attempts to write in amusing and witty fashion of the prosaic things of this world and the insulting lampoon as there is between "Spy's" caricature and the series of articles to which we have alluded, where every suggestion, from gross ignorance to actual moral impropriety, is made against an honourable profession. We do not want to suggest that our contemporary keeps all his insults for the medical profession, for that is not so. Paragraphs frequently appear regarding political or other opponents which make even holders of the same political creed as our contemporary wonder what was the origin and education of the writer. Members of every profession suffer from their personal idiosyncrasies, and, in a small proportion of cases, idiosyncrasy is a mild term by which to stigmatise their moral obliquities, but that does not make their profession, as a whole, a fitting subject of insult. As well condemn a writer in the *Times* or *Spectator* for the ill-bred effusions of another journal. Newspapers have their public, and must write up or down to their level as the case may be. We find it, however, difficult to believe that the public of *Vanity Fair* demands or requires such writing down as at times, disfigures the columns of that journal. It is little wonder that a prominent member of the medical profession should object to the unauthorised appearance of his caricature amidst the surroundings in which he finds it, even though the same caricature in other surroundings could be regarded as nothing save a compliment. To find in one part of a journal a slanderous article on the profession to which we belong, and in another part our own unauthorised portrait, or caricature, is quite enough to raise the indignation of any honourable man.

Notes on Current Topics.

Modern Mithridatics.

The announcement of the discovery of a serum for whooping-cough—a discovery the value of which we are not as yet in a position to affirm, follows in the wake of the preventive inoculations for diphtheria, anthrax, tetanus, hydrophobia, pyæmia, &c. The list is already of respectable length, and the immunity afforded by these various sera is indisputable even in respect of those whose curative powers are still somewhat uncertain. We seem to be in a fair way to realise the feat of King Mithridates in inuring ourselves against the various poisons which threaten our frail existence. The results achieved by this potentate in the domain of toxicology are inconclusive and ill-authenticated, but those of our scientific investigators repose on a sounder basis. Unfortunately, modern discoveries in immunisation bear for the most part on diseases which each one of us is reasonably entitled to hope he may escape in the natural course of events. Nevertheless, if we knew positively that the immunity afforded by these sera would be durable it might be thought desirable by the more prudent to run through the gamut of vaccinations. As a matter of fact, however, the duration of the protection is in every instance a moot point, and as in some instances it probably only lasts a month or two, it hardly seems worth while. Immunity against typhoid fever, pneumonia, syphilis, scarlet fever, and old age, would be highly appreciated, but they are not yet on the market. The time may come, nevertheless, when the maxim *medicina tota in observationibus* will have to be modified in favour of prevention.

Berlin Conference on Tuberculosis.

It is characteristic of the altruism of medicine that all the gleaners in the field of medical science willingly contribute to the general stock of knowledge. The amount, like a rolling snowball, grows until its proportions attain a size that even professional men need to be reminded of. In telling the story of accumulated knowledge, diffusing it abroad, and exciting interest in special subjects medical conferences play an important and useful part. But, as a rule, they themselves contribute little to our information on obscure subjects, and too often the early workers in the field are lost sight of, and honours justly theirs bestowed on others. The recent Congress on tuberculosis in Berlin is a good example of this. The whole proceedings might be read from start to finish without discovering any recognition of the claims of British workers, though the whole of our knowledge of the etiology and treatment of the disease is their work. As far as British writers and physicians are concerned, Bodington has lived in vain; at least, his views were not accepted until they came back to us with the legend, "made in Germany," and rechristened the "Nordach" treatment. Yet the reader of Ziemssen finds nothing to warrant the claims of Germans to this, the greatest triumph of the physician during the nineteenth century. Now Ziemssen's cyclopædia was commenced about 1872, more than thirty years after George Bodington's modest essay of thirty pages. And to-day, we cannot better Bodington's therapeutics, "the most important remedial agent in the cure of consumption, that of the free use of a pure atmosphere; not the impure air of a close room, or even that of a house generally, but the air out of doors, early in the morning, either by riding or walking. The diet nourishing, consisting of boiled egg, fresh meat, milk and bread, and two glasses of sherry in water daily." We need not multiply examples, but we may just name as workers, Lynch, McCormac and Ryan, names familiar to students of British medicine, though seldom referred to in the medical literature of the day.

An Automatic Fever Indicator.

It is obviously of great importance to know exactly when the temperature of a given patient reaches its maximum, a point which may fail to be ascertained should it fall at a time intermediate between the regular hours for taking the temperature. Moreover, the mere fact of the temperature attaining a certain elevation constitutes an indication for antipyretic measures calling for immediate attention. In order to fulfil these desiderata an ingenious French physicist has invented an apparatus which sets a bell ringing when the fever rises above the point at which it has been set. The essential part of the apparatus is a clinical thermometer in which the mercury on rising completes an electric circuit. This index-thermometer is placed in the patient's armpit, and connected up with a bell circuit which rings in the house-physician's room, warning him of the necessity for his presence. It is claimed that this device will render it possible to reduce the number of nurses, but this sanguine view is based on a misconception, because taking the temperature is perhaps the least important of the nurse's multiple duties. Many other automatic apparatus will be necessary before we can deplete the nursing staff of our hospitals.

Personation and the General Medical Council.

A correspondent has written us sharply criticising our recent leading article on "Personation and the General Medical Council." He interprets the remarks made with regard to that body as an assertion that the Council will not accept responsibility, and, further, neglects its duty in that direction. That impression certainly does not represent our view, which suggests that the Coun cil fails to put a reasonable effectual check upon personation because of the radical defects of a system which is no system. Our correspondent asks, What should be the duty of the Council in the prevention of unqualified practitioners? Should a person be employed in each town to watch every medical name-plate that is put up, and to investigate the *bona fides* of the newcomer? We decidedly think that something should be done in every such case, and fail to see why special officers for the purpose should not be appointed by the Council, which has accepted th responsibility of maintaining the integrity of the "Register." One official could manage several counties were the Council to establish some simple system of communication with medical men throughout the United Kingdom, asking for information as to newcomers. The present plan adopted by the Council is unworthy of confidence. Reform in this direction we regard as closely connected with the recasting of the General Medical Council with fresh powers and a fresh constitution. A popularly elected and popularly controlled governing body would be more likely to handle with firmness and wisdom a question so vital to the material interests of the profession as that of personation. Medical men would hardly grudge the spending of money upon practical issues that would add so materially to their own safety and protection. Increased funds would readily be obtainable from compulsory annual registration, and would repay the profession a thousand-fold. What is wanted is a Council with the popular interests at heart.

Body Snatching in America.

Great scandal has been caused in Indianapolis by an epidemic of body snatching, and twenty-five persons have been indicted for aiding or abetting in the commission of the offence. Five of the inculpated are physicians charged with complicity in that they neglected to keep a proper register of bodies received for dissection. It was stated by one of the witnesses that upwards of a hundred bodies had been "snatched" during the past year. Obviously such things ought not to be, but their very occurrence is *prima facie* evidence of a lack of provision for the requirements of anatomical studies, otherwise it would not be worth while to take all this trouble. The abuse in this country was stamped out once and for ever by an Anatomy Act which rendered it possible to obtain anatomical material without desecrating graves, or converting, as did the celebrated Burke, living beings into subjects for dissection. It is odd that our American contemporaries in commenting on the scandal do not point out this obvious moral.

Moral Insanity.

A form of insanity which is apt to escape recognition is that in which the sexual instinct furnishes the "irresistible impulse." It is possessed of considerable medico-legal interest, although at present it would be idle to plead even attenuated responsibility in favour of prisoners charged with sexual crimes. Aberrations of the sexual passion are, however, among the most marked and obstinate manifestations of mental defect or impairment, but, unless they happen to be associated with depreciation of one or other of the higher intellectual faculties, the law declines to take cognisance thereof. These aberrations are specially well-marked in neurotic subjects, more particularly in those of epileptic descent, a fact which affords *prima facie* proof of the neurotic origin of the impulse. There is a close connection between certain forms of sexual aberration and homicidal proclivities, and this is another proof of mental derangement. In short, these abnormal sexual manifestations are in a large proportion of instances merely premonitory of grave psychical disturbances, and it behoves criminal psychologists to study them from this point of view.

The Holding of Inquests.

It has long been matter of common belief that the present death registration and death certification machinery of the United Kingdom is in so unsatisfactory a condition as to demand early reform. When that issue is fairly placed before the Legislature one of the points that will have to be "fairly and squarely" faced will be that of the coroner's duty with regard to the holding of inquiries into deaths where the certificate of a registered medical man is not forthcoming. A specific direction to coroners to hold inquests upon all uncertified bodies would raise the whole question of proper and efficient death registration in a practical and far-reaching manner. With a threat of that kind constantly hanging over his head the unqualified practitioner would soon be inclined to take a less rosy view of his irregular calling. The permissive nature of medical registration would also be in all likelihood rendered practically needless, for no medical man would care to attend cases of illness with an ever-present risk o subjecting the friends of his patients to the unpleasantness of a public inquest. No medical practice could survive a sham of that kind for any length of time. At present a coroner is directed to hold an inquest where there is reasonable cause to suspect that any person has died either a violent or an unnatural death, or has died a sudden death of which the cause is unknown. On the whole it seems likely that coroners hold too few rather than too many inquests. The latter view is usually advanced by local authorities who object to open their purse-strings for the general protection of the public.

Should the Appendix be Outlawed?

CURIOUS as it may appear, the question has been raised whether the surgeon is justified in removing the vermiform appendix when he comes across it in the course of operations undertaken for other reasons than appendicitis. Dr. Howard Kelly, of Baltimore (*a*), has been at the trouble of catechising his surgical *confrères* on the subject. The replies show that, as might be expected, no uniformity of opinion exists as to the propriety of removing the appendix in the absence of obvious disease, and the majority answered in the negative. When, however, the appendix is slightly adherent to neighbouring structures, most surgeons declared it their practice to remove it. This conclusion is so obviously in accordance with general surgical principles that it hardly seems to have been worth the trouble to obtain it. The fact that the appendix has no known function does not prove it to be a functionless organ, although, as Dr. Kelly observes, we are in the habit of assuming this to be the case. It is confidently asserted that the normal appendix never contains fæcal concretions, and among other reasons which may be held to justify its removal the presence of such concretions is one. Moreover, it is urged, not without a show of reason, that the existence of an appendix long enough to enter the field of an adjacent operation exposes the patient to the risk of subsequent adhesions and should therefore be removed. The outcome of Dr. Kelly's experience is that the appendix should always be examined and its condition noted whenever the abdomen is opened, provided no additional risk is entailed thereby; that its removal is justifiable when it is found to be slightly adherent, when it contains fæcal concretions, and, as a matter of routine, in operations for the removal of the right ovary, in order to obviate the risk of adhesions.

Statues of Medical Men.

PHYSICIANS and surgeons and scientists generally are but slowly coming to their own. The man who usually wins popularity is one who appeals to the sentiment of the populace and in his life and work arouses the emotional nature of the people. Comparatively few memorials to medical men can be found at Westminster Abbey or in St. Paul's. Our provincial towns are not without monuments to local celebrities and forgotten benefactors, but permanent records which may remind the man in the street of the labours of medical practitioners who have passed to the majority are rare indeed. And, as far as we can remember, the only members of the nursing profession who have been fixed in imperishable stone or metal are Miss Florence Nightingale and "Sister Dora." We are glad to find that there is a growing tendency to accord to medical men honour and justice in regard to this matter, and we note with pleasure that outside the very beautiful town hall at Colchester, "the oldest town in England," an elegant marble statue has been erected of Dr. William Gilberd, the famous physician to Queen Elizabeth. But 1540-1603, during which years Gilberd lived at Colchester, throws us back to almost forgotten days. Still it is well that at the commencement of the twentieth century this distinguished scientist should have his memory rescued from oblivion. But it should be remembered that the statue has been presented to the Corporation of Colchester by the medical profession in that town.

The Pathology of Articular Rheumatism.

IT is extremely probable that under the genera designation of articular rheumatism are comprised several distinct morbid processes which a certain clinical similarity has caused to be grouped under one head. This assumption would go far to explain the want of uniformity which obtains in the onset, course and termination of these cases. The view is steadily gaining ground that the typical acute articular rheumatism is an infectious disease, its subsequent course being largely determined by individual constitution. Just as certain persons become infected with tuberculosis by reason of defective resistance on the part of particular tissues, so others are amenable to the rheumatic poison in consequence of a morbid proclivity on the part of the serous membranes. The joint structures are made up of delicate tissues upon which devolves a large amount of work, and any depreciation of vitality renders them amenable to morbid influences. We witness this depreciation of vitality in association with chronic alcoholism, renal disease, and in certain blood dyscrasiæ such as hæmophilia and scurvy. To these secondary and accessory states must be attributed the persistence of the rheumatic process beyond the average. This predominance of the personal factor must not blind us to the variable nature of the constitutional disturbance which may pave the way to inflammation of the joint structures, and the effects of the salicylate medication will often assist in the differential diagnosis. Cases which resist this treatment should always be regarded with suspicion, and search made for another explanation of the symptoms.

Glycosuria and Graves' Disease.

GLYCOSURIA, if not a constant, is a very common symptom in the subjects of Graves' disease, and the relationship between the two is an interesting point in the pathogenesis of the latter affection which has not yet been satisfactorily explained. True diabetes is also met with in this connection, but in a somewhat smaller proportion. Glycosuria in any form is vastly more common in females suffering from exophthalmic goitre than in males, the proportion being several times greater than that of the occurrence of this disease in the sexes respec-

(*a*) *Journ. of the Amer. Med. Assoc.*, No. 17, 1902.

tively. In view of these facts, it is difficult to accept as probable the view that the coexistence of glycosuria and Graves' disease is of the nature of a coincidence only. Moreover, it has been noted that when the glycosuric element is present the prognosis is thereby aggravated, suggesting that the constitutional impairment is greater than in the cases in which it is absent. The administration of thyroid extract in these cases provokes at first an increase in the excretion of sugar, but when this treatment has the effect of improving the characteristic manifestations of the fundamental disease, it also determines a decrease in the output of sugar. It is now generally admitted that in all probability Graves' disease is due to the perverted action of the thyroid gland or of the parathyroids, or both, and it is possible that functional disturbance of these glands may also account for the occurrence of diabetes. It is worthy of note, on the other hand, that the administration of large doses of thyroid extract is often followed by the temporary appearance of sugar in the urine when it was previously absent. It may reasonably be inferred that the two morbid conditions have some common factor, and that factor may be either a disturbance of circulatory equilibrium or a far-reaching influence on metabolic exchanges.

Friendly Societies and Sanatoria for Consumptives.

If the sanatorium treatment of consumption is ever to be placed on a footing at all commensurate with the requirements of the labouring population it can only be on the initiative of friendly societies and similar associations. They have every incentive to take the matter in hand, because the sickness allowances of their consumptive members constitute a heavy drain on their resources which, under existing conditions, remain until the malady terminates in death. Dr. Hillier's suggestion that deputations from the friendly societies of this country should visit Germany to observe the administration of the State Sick Insurance Fund has much to commend it, if for no other reason that it may stimulate them to take into consideration the desirability of adapting the system to their own requirements. Each friendly society might have its own camp for consumptives, a plan which offers many advantages over the erection of costly sanatoria which could only accommodate a limited number of inmates.

It is officially notified that His Majesty has consented to open in person the new out-patient department of the London Hospital at a date to be subsequently fixed.

The late Dr. Thomas Fitzpatrick, F.R.C.P., has bequeathed the sum of £1,000 to Trinity College, Dublin, to found a prize which shall be awarded to the candidate who obtains the highest aggregate of marks at the final examinations in the School of Physic.

Street Accidents.
